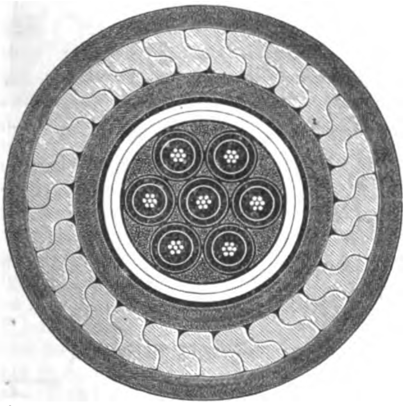
To effectively meet these difficulties was by no means easy. After minute examination of the question by the Swiss telegraph authorities, the Felten and Guilleaume cable, the section of which is shown in full size in the accompanying illustration, was adopted. The conductors are each composed of seven No. 22 copper wires, the strand being insulated with alternate layers of Chatterton compound and gutta percha to a thickness of 0·236in., and then taped. Seven such gutta percha cores are stranded together and the whole taped and tarred. To protect the cores from the gases and water in the tunnel they are encased afterwards in a double lead-covering. The latter is served with insulating material, chiefly compound, and packing, and over this are placed 25 peculiarly-shaped wires which interlock and form an extremely firm and close sheathing; finally the cable is served with asphaltum, the diameter over all being about 2in. The total length of the cable is about eight miles. In addition to the seven-core cable a quantity of cable of the same construction, but having five and four cores, was supplied for special connections.

The next consideration was the laying of the cable. This was done under the supervision of Dr. V. Wietlisbach, of the Swiss Telegraph Administration. It was determined to have the cable laid in the same trench as the former cables, but as there was no space left at the same depth beneath the ground, and it being no longer possible to widen the trench, the only alternative, in order to avoid the difficult and costly work of constructing another trench, was to lay the new cable above the previous ones, and the new cable has been laid in this way, separated from the others by sand, and covered by a



Cross-section of the St. Gotthard Telegraph Cable, Full size.

layer of sand and stone slabs, the trench being then filled up with stones or pebbles. The laying of the cable was carried out as on former occasions, that is to say, the rotating wheel on which the cable was carted was placed on an open truck drawn by a locomotive, thus allowing the cable to slowly unwind from the reel. The laying of the cable, as well as the conveyance of material, could only be done in the evening between seven and nine o'clock, on account of the immense traffic on the line. The jointing, however, was done at night. The jointing was an exceedingly difficult task, as in consequence of the atmosphere being so damp, and besides impregnated with coal and ash-dust, it was almost impossible to keep the hands and tools clean, even for a short time. The damp and trickling water moistened the ends of the cores, often causing small faults in the insulation, in spite of the utmost care. However, by means of a sensitive mirror galvanometer placed at the Göschenen entrance, these faults were detected and eliminated. It will be readily understood that work of this kind in such an atmosphere (made worse by the flickering torches and the high temperature) was exceedingly difficult. The joints were enclosed in iron joint boxes specially designed by the contractors to protect them both from mechanical and chemical injury.

The cable is connected up at the Göschenen and Airolo stations, and there provided with lightning arresters. The electrical tests specified for the cable by the telegraph administration are as follows:—

Copper resistance, 7 ohms max.	Per kilometre at 60°F.
Insulation resistance 1,000 megohms min.	
Capacity 0·25 microfarad max.	

The tests after the cable was laid gave the following far more favourable results, viz.:—

Copper resistance, mean, 6·35 ohms	Per kilometre at 60°F.
Insulation resistance, mean, 7,500 megohms...	
Capacity, mean, 0·193 microfarad	

SOME NOTES ON THE ELECTRIC LIGHTING OF THE CITY OF LONDON.*

BY MAJOR-GEN. C. E. WEBBER.

(Continued from page 427.)

What was probably one of the most difficult parts of the task was the description of the details of the adaptation of portions of the plant to sites and buildings still under design, so that no extras on the contracts should arise, and thus the equipment of the stations and sub-stations should be of the most complete and up-to-date description, and fully equal to the requirement of the capacity which the contractors had undertaken to provide. Both sites presented exceptional features, and the designing of the building structures for each differed entirely. That for the Wool Quay (since abandoned)† required a building in which the floor of the basement would have been 20 feet below high-water mark, and the station plant should be placed on floors one above the other; the generators to be in the basement, the boilers over (on a Hobson's steel girder floor), and the coal above. The site at Meredith's Wharf, although the essential features of the first design have been retained, has been so enlarged that any description of it that might be attempted in this paper would not be sufficient.‡

The estimate of the load-factors of the *public* lighting of the City may be here made with some interest. Adopting Mr. Crompton's figure, which allows 25 per cent. for extra or reserve machinery, in the case of the public lighting the capacity of the plant is 890 − 222 = 668 kilowatts, or 5,851,680 kilowatts per annum. The 515 arc lamps represent 257,500 watt hours, and the 906 glow lamps—half being 100 watts and half 50—represent 67,950 watts more, or a total hourly consumption of 325·45 kilowatt hours, which, with 4,030 running hours in the year, gives a load of 1,311,562 units per annum. But, in fact, the amount of the above plant that is spare, or available for arc lighting in public buildings or elsewhere, is very large, and it is better to regard the actual capacity of the plant exclusively devoted to public lighting, including reserve, as represented by sixteen 50 (500-watt) light machines, with an annual total capacity of 3,504,000 kilowatts. This will give a load-factor of 37·4.

DISTRIBUTION.

Outside the Postal Telegraph and the City Engineer's office there was no one who could form any accurate idea of the condition of things below the surface of the City streets. The subways in Queen Victoria-street, in Arthur-street, and in the Holborn-viaduct, although suitable for through mains of supply of any kind, were eminently not so for electric distribution conductors, which have to be tapped at frequent intervals for the supply of current for public and private lighting. Although forced to use them, the cost of such mains and services to a supply company is higher than if the lines were laid under the footway on either side. In March, 1890, the London County Council, with the approval of the Board of Trade, and the confirmation of the Home Secretary under the terms of the Metropolitan Subways and Government Acts of 1868 and 1888, had published by-laws for regulating the use of subways. These, while in force in the Queen Victoria-street subway, are not so in those under the Holborn Viaduct and Arthur-street. Anyone who has used street subways for electrical conductors, in common with gas, water, and other companies, will understand that, except for primaries, the

* Paper read before the Institution of Electrical Engineers, February 8, 1894.

† This site had to be taken over by the City company under the "concessionaire" contracts.

‡ The Institution will be better served if I leave it to the gentlemen who were selected by me as my assistants for that part of the work, and who have actually since carried it out—namely, Colonel Seddon (late R.E.), and Mr. C. Thompson. The meeting will, I hope, understand that in refraining to give any detailed description of the equipment of the stations I am influenced by the wish that such should be undertaken either by the engineers of the respective contractors who designed and erected them, or by Mr. J. H. Jackson (one of my assistants), who is still superintending the same. As regards the building structures, I may, however, add that of three chimneys designed, and specified and contracted for under me, one—*i.e.*, that now to be seen close to Bankside—has been erected. There are features of its construction, especially with reference to the bond, that I should like to have time to describe. Its cost was £2,075, its height 150 feet, and its internal diameter 12 feet.

Digitized by Google

electrical engineer would much rather remain outside. The by-laws are excellent for the regulation of this user, but the panacea which excellently-intentioned persons believe exists in street subways falls short of theirs and the public's expectations. The law allows the local authority to oblige us to use them where they exist, and to charge us a rental for that use; but, as the word "pipe" in the Act includes a "tube for wires," and as the rental, irrespective of the number of wires, is £16 per annum for a 3-inch pipe for the 1,200 yards of the Queen Victoria-street subway, and £49 per annum for one under 18in. diameter for the same length, the way-leave is not very costly, but the cost of using it is extremely so.

Sections of some of the subways, with the conduits placed in each for lectric light conductors, are shown. In each case the obligation

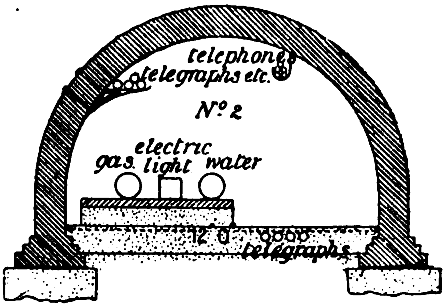


FIG. 1.—Holborn Viaduct Subway.

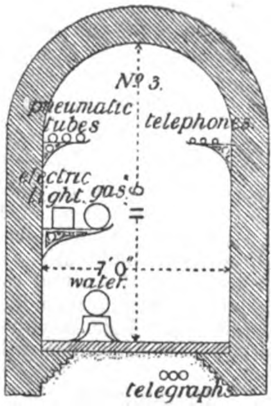

FIG. 2.—Holborn Viaduct Narrow Subway.

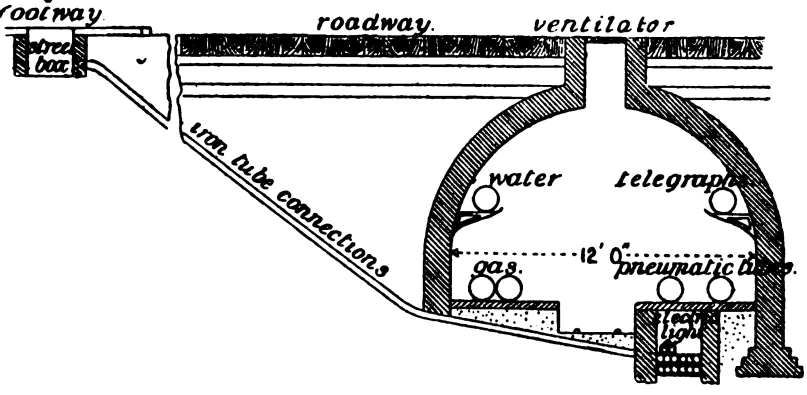

FIG. 3.—Subway, Charterhouse-square, with Street Box.

to use the subway instead of the ground under the footways entailed one excessive expenditure common to both—namely, the works in breaking through the massive arches and deep cuttings in the roadways to get at the street lamps, and, in many places, to obtain access to the houses, in some places 30ft. away. In the Arthur-street and Holborn Viaduct subways a large number of "ways" in Callender-Webber casing have been secured at a very little cost.

In the Queen Victoria-street subway cast-iron troughing on wall brackets, as first designed, proved an awkward and costly arrangement in many ways; the weight of the structure was nearly 3cwt. per yard. Lighter troughing designed by me was adopted, of which follow sections.

The trough contains cables—six of 1·9" external diameter, three of 1·5" external diameter, and four of 0·7" external diameter; with a carrying capacity in section of copper available at 2,000 volts =0·09", at 200 volts=2·1". Weight of trough per yard=90lb.; cost of trough, fixed, 16s. per yard—with conductors, high-insulation bitumen, £4. 2s. per yard run. The essential objections to working in such subways (apart from maintenance) are—(1) The difficulties, physical and otherwise, of access to them, both for *personnel*, material, and plant; (2) the delays to work, due (*a*) to defective lighting, (*b*) time required to communicate with the authority and other occupiers, (*c*) to foul atmosphere; (3) the engineering obstacles due to the works of previous occupiers, and to the cutting in and out where necessary to reach side streets.

My own Postal Telegraph experience in 1871 and 1872 had been in the difficult ground in thoroughfares like Cornhill; and although in 1891 and 1892 places were come upon where hardly a single conduit could be laid, the task, owing to the system adopted, proved, on the whole, less difficult than was anticipated; and, as was expected, generally, the thoroughfares running north and south were easier than those east and west, for the reason that most water, gas and telegraph mains, tend from the City towards outside centres in those directions. The pioneer work included the opening of certain main thoroughfares, so that the arc lighting might be got forward. In these, the most thronged streets of the City, it was essential not to have to repeat the inconvenience of opening the ground. Whatever was laid down at the first operation had to form a portion of, and suffice for, the completed scheme.

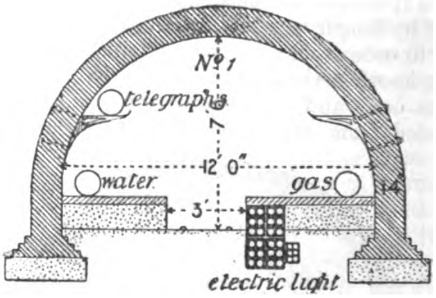

FIG. 4.—Subway, Arthur-street.

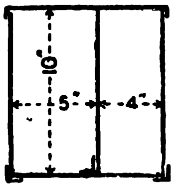

FIG. 5.—Section of Square Trough.

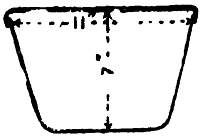

FIG. 6.—Section of Rolled-Iron Trough.

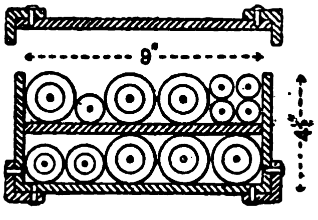

FIG. 7.—Section of Trough with Cables laid in.

In a matter so long under my own consideration I had no hesitation in recommending that sufficient conduit accommodation should be provided and that it should take the following form, viz.:—* (*a*) Iron pipes for concentric high-tension mains from the generating to the transforming stations. (*b*) Iron pipes for continuous-current high-tension mains for the public arc lighting. (*c*) Bitumen concrete casing for three ways, to accommodate the conductors of a low-tension distributing system, both feeders and distributors. The future needs of the great whole had, as I shall describe further on, to be thought out before March of 1891, so that each part of the work, however preliminary, should eventually fit into the permanent system. The future need for

* The entire responsibility of thus advising the Pioneer Company rests with me. As the pioneer contracts (with the making of which I had nothing to do) had only provided conduits sufficient for the cables from the pioneer generating stations, and had specified nothing as regards the underground conditions, it was necessary, in order to prevent the consequent waste of having to excavate the same ground twice, to make additional provision. And as the isolated areas treated by these pioneer contracts had to be considered as forming a part of the great whole, the whole of the details of the completed work had to be gone into.

Digitized by Google

spare conduits, possibly for telephones, had also to be thought of, and it was provided for as far as the very limited space under the footways of those thoroughfares which were first treated would permit.

The question of interference, through the neighbourhood of alternating-current working, with telegraph and telephone circuits was at that time under public discussion. I had very little time, and had to be satisfied with one experiment having the object of observing the screening effect which was anticipated would exist through the interposition of what might be called "faggots" of iron pipes, lying in the same trench as the non-conducting conduits, into which the low-tension distributing mains were to be drawn. For the experiment, conduits and pipes were laid on trestles under nearly the same conditions as in the trench, and a 200-volt current with 100 frequency (obtained by transformation) and 100 amperes was passed through two of the three ways of a bitumen concrete conduit, in conductors having a sectional area of copper of about one-tenth of an inch. Telephone circuits with metallic* returns laid parallel were tried. The iron tubes were placed at various distances and in various numbers. Imperfect as the trial was, it gave us security that at a distance of 12in. from the Callender-Webber casing, twin telephone circuits in iron pipes would be fairly secure from trouble. But, as an additional precaution, it was decided to sheath the casing with iron. Within a distance of about 6in. a very slight disturbance could be still heard. The choice was further justified, because the Duke of Marlborough, with his usual foresight, asked several practical engineers to meet him in a friendly way soon after this advice had been given and adopted, in order to discuss the whole question. From my notes of that meeting, held on March 23 and 24, 1891, I find the conclusions then come to coincided with the system above referred to, which was already in course of execution. Those present at this meeting were the Duke of Marlborough, Messrs. T. Callender, Gordon, Gray, Heaviside, Mavor, Raworth, A. Siemens, Wharton, and Major-Gen. Webber. It is not to be assumed that unanimity on matters of detail was expected or arrived at. As regards anticipated electrical troubles, the avoidance of interruption of telegraph and telephone circuits was the only thing dealt with at those consultations. Those present had till then had, I must presume, no practical experience of the resistances due to skin effect, or self-induction, in the case of single conductors of over one-third of an inch section of copper used to convey alternating currents at *low* pressure. The use of concentric lead-covered cables laid in the earth, with iron split-tube protection where joints have to be made, was discussed with the advocates of that system as used in Germany, and its advantages, both as to reliability, manageability, and first cost, in comparison with two or more highly-insulated conductors in one iron pipe, were weighed, especially in view of the claim that, wherever laid, it is everlasting. The question of influence on telegraphs and telephones, and the means of screening or damping down the magnetic field, was discussed, and various experiences at Bath, Newcastle, and in London were quoted.

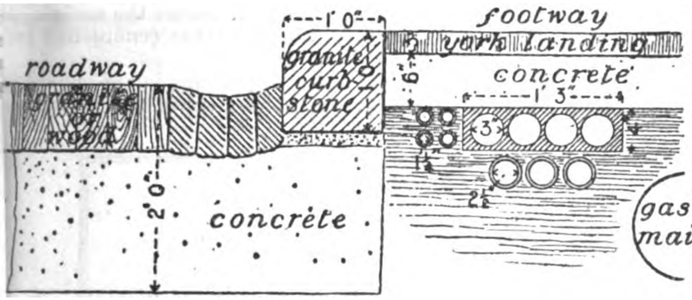

FIG. 8.—Sections of Road.

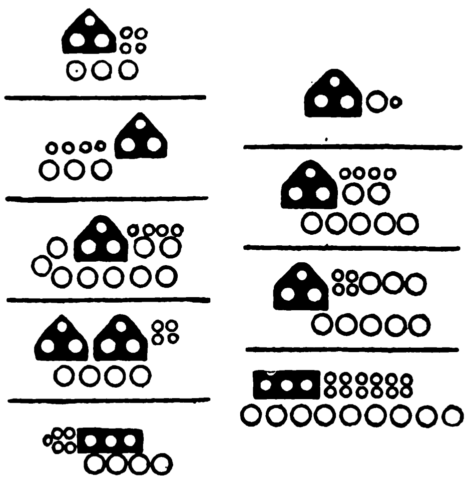

FIG. 9.—Various Typical Sections of Conduits.

The following recommendations were formulated, with general concurrence:—(1.) That a separate way should be provided for each separate conductor, for the purpose of drawing in and out between flush-boxes. (2.) That the high-tension primary alternating currents should have concentric conductors with vulcanised rubber dielectric, and be drawn into iron ways. (3.) That the arc lighting continuous-current conductors should be concentric, and drawn into an iron way, except in the lengths where the circuit is connected with lamps, when the 7/16 conductors should be separate, so as to avoid joints.

In connection with the secondary distributing conductors, the use of the three-wire system having been admitted, various means of laying were examined—such as large iron pipes, with and without interior separate ways for the cable; the use of paper tubes in iron cases; iron tubes lined with bitumen; and earthenware cases, with ways similar to the Callender-Webber bitumen concrete cases. After carefully considering the conditions of the City streets, and all the circumstances of difficulty that were being met with and known to exist, the use of bitumen concrete cases with separate ways; and, in view of the experience and evidence of its efficiency, the use of Callender's bitumen insulation for the secondary distributors, met with approval. After hearing all that was to be said as to the conditions for providing drawing-in and joint boxes in the City streets, no doubt remained as to the necessity for using a common box in most situations for all main circuits and their joints, and of making them as large as the space below the surface would permit.

The justification of the adoption of these resolutions was, both from the engineering and financial point of view, as follows:—The use of footways wherever possible had been prescribed by the Commissioners. In spite of having to keep six inches under the lower side of the paving-stones, it entailed less labour in excavating. In the lines where they had to be carried under roadways, the conduits had to be below paving and concrete, sometimes 2ft. in thickness, and with a surface subject to such traffic the numerous draw, service, and other flush boxes would have been impossible.* The space available below the surface was occasionally entirely occupied by cellars, areas, and other pipes, and the work had to be carried out in the presence of officials representing—(1) The Commissioners of Sewers, (2) the Postmaster-General, (3) the Gas Company, (4) the Water Company, (5) the Hydraulic Main Company, (6) the District Surveyor.

The condition, exacted rigorously—namely, that no pipe or conduit should be placed vertically over, or within 6in. horizontally of, an existing pipe—was a most arduous one to fulfil. My procedure in the most difficult streets was as follows:—Having decided on the maximum number of "ways" that should, and if possible be, laid under the footway, I began by examining it personally, having first obtained from the authorities I have named all possible information as to their pipes—information that was sometimes very imperfect. I then measured carefully all cellars, arches, and areas, and had trial holes opened wherever exceptional difficulty was anticipated. In many cases, such as in King William-street, so contracted was the space that several ways which were actually necessary had to be omitted and taken another way, and occasionally a deviation under the roadway was obligatory. The intricacies of the trench opened under such conditions could not, I believe, have been followed with any other system of ways, namely, the combination of Callender-Webber casings and wrought-iron tubes. Both these are capable of being bent on the ground to any reasonable curve—in the case of the iron pipes by the ordinary means, and in the case of the bitumen concrete cases either by warming the case and bending it when soft, or by laying short lengths and setting them at an angle to one another with mitred ends; the length of the short pieces and the angle of the mitres being, of course, dependent on the radius of the segment of the curve that has to be followed.

* Experiments made in 1880 with telephone circuits with and without earth returns, between Paddington and Westbourne Park Stations, laid in the same wooden troughs as 40 or 50 working single and double-current telegraph circuits, saved me from having to make any trial with earth return for the telephones.

* The following figures give an idea of the traffic in the City:—By bridges, streets, railway stations, landing piers, and subways there are 81 means of public access. By these the *daily* traffic was—

		1881.	1891.
Vehicular—	During 16 hours	66,909	85,286
	During 8 hours	4,984	6,546
Pedestrian—	During 16 hours	739,640	1,100,636
	During 8 hours	57,923	85,458

Digitized by Google

The difficult problem that faced the Company in August, 1891, was the obligation to lay down their mains and complete the public lighting in all or parts of 53 streets by February, 1892, requiring approximately 17 miles of trench; and that the Commissioners were likely to be very stiff as to punctuality. A careful consideration of the case in its various aspects had led me, when acting (up to and before 1890) as technical adviser to the Brush Company, to regard the adoption of alternating currents, delivered at high pressure and distributed at low pressure, as the service most suitable for private lighting in the City. There was no hesitation on the part of all concerned to adopt it, particularly as in the case of the contractors the Mordey and Thomson-Houston systems had in 1890 reached considerable perfection. The conditions which emphasised this view in my mind were geographical and local as regards the City. Whatever may have been the ultimate practice, they were paramount during the preliminary stage. They were, first, on account of cost of ground, that the generating stations should be at a distance; second, on account of the exceptional difficulties in the streets for laying mains, the desirable frequency of converting stations might be impossible to achieve. When the concessionaires (*i.e.*, the contractors) had the matter in their own hands, the sites already named for the generating stations were secured in, or in close proximity to, the City. Although this was a reversal of conditions, the selections were easier to have first found sites for the sub-stations and then arranged the areas to be served by them; but, as the main thoroughfares traversed the City throughout in all directions, there was no area that was not touched by the work requiring immediate completion, so that, to be able to get the above-named 17 miles done, all had to be considered in advance.

The combination of casings with 1¼in. and 2¼in. pipes required a minimum sectional area of trench varying according to locality, and if the soil below the footways had been comparatively free there would have been little difficulty in arranging the position of the ways relatively to one another, so as to suit all requirements. It was essential—(*a*) To place them so that the relative positions of the ends should coincide at any rate between box and box, no matter what might be their vagaries in the interval. (*b*) That, where the trench was opened alongside of a line of pipes enclosing telegraph conductors, the mass of the iron pipes should be laid between the alternating low-pressure conductors and the same, to aid in screening the inductive effect on the smaller currents. (*c*) That the ways destined to be used for the arc lighting, and for the distribution in the street itself, should be nearest the surface. As it was, the fulfilment of these and all other conditions I have mentioned was often absolutely impossible.

The obligatory positions of boxes for drawing in and out and for access to the cables (exclusive of house service and street lamp

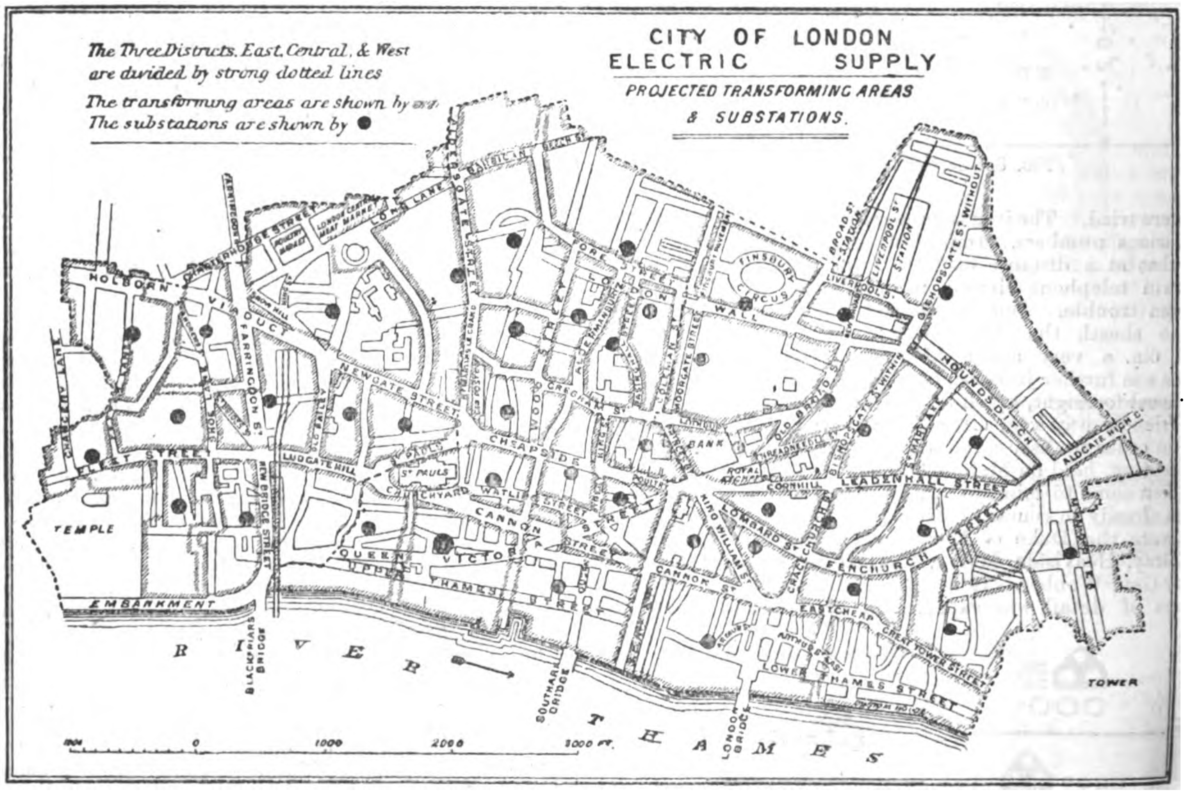

FIG. 10.—Map of City, showing Transformer Sub-stations.

probably wisely influenced by question of facilities for sea-borne coal and condensing water, and largely controlled by the difficulty created by the Electric Light Acts in getting way-leaves through the areas of neighbouring local authorities.* The facility, or otherwise, of obtaining sites for transforming stations could not be fully gauged during the preliminary stage, and space underground to be found for large conductors could only be expected to a very limited degree. If we had only known as much as experience has since shown, it is quite possible that a continuous-current system of distribution would have had as good a chance of being adopted as the alternating system.

Distribution with low pressure from transforming stations entailed a network on the well-known lines, with distributing service mains and feeders. When the time arrived for the City to be divided into areas, each to be served by a transforming station, with all the stations, if not the areas, intercommunicating, the areas and points for the stations had to be approximately assumed, and the number of ways estimated that would be required under each footway throughout the whole City. It would have been, of course, boxes, which were only for access to the cables required) were numerous, as it was necessary to place one at every street corner, and wherever a serious change of direction occurred. Still, the lineal space of line of main occupied by boxes was, on an average, only about 2 yards in every 100. These boxes were made as large as possible, which is not saying much; I aimed at making them large and deep enough for a man to get entirely inside, but this was rarely possible. Owing to the obstruction underground, they are of every conceivable size and shape.

Drainage, and access of gas from the surrounding soil, are conflicting conditions. The drainage had to give way unless some nearer outlet was evident, and the boxes were made as gas-tight as cement and glazed or impervious bricks could make them. The question of the presence of explosive mixtures in street boxes has, as my audience knows, been several times brought to notice by explosions—one lately in the Western district, on Ludgate Hill. My own view of this particular condition of danger has been to do everything to prevent the coal-gas getting into a box, and I believe this can be secured with proper precautions, apart from the occasional possibility of being able to ventilate by in-draught and out-draught ducts. The precautions are—(*a*) Good joints between case and case, ensured by finally passing the red-hot "mouse" through each joint after the casing has been laid; (*b*) absence of air space between the cases and the iron sheathing; (*c*) careful sealing

* For instance, negotiations extending over three years, with that object only, that I had conducted for the Brush Company with some local authorities on the Surrey side, ended in only obliging the Company to seek and obtain a Provisional Order for the St. Saviour's district.

Digitized by Google

in round the iron tubes and bitumen cases where they pass through the wall of a box ; (*d*) careful plugging of all "ways" not in use, and caulking with tarred yarn round the cables where they emerge from the "ways" ; (*e*) the use of drainage only where the pipes are sure not to become ducts for gas ; (*f*) ordinary care in the use of lights until gas is clear.

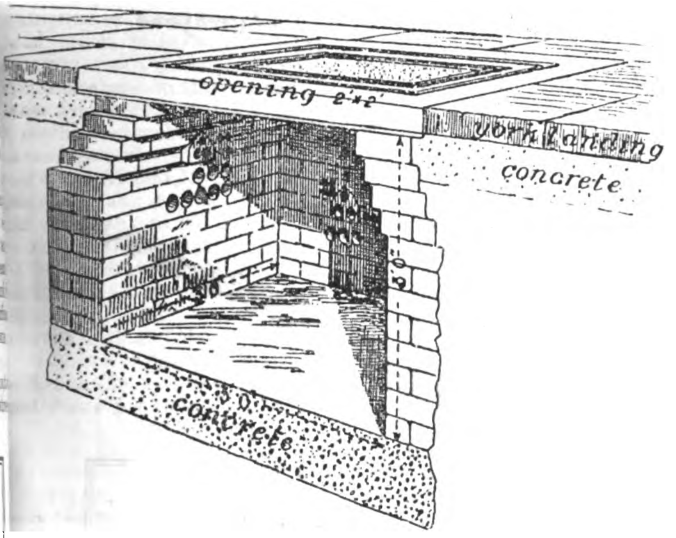

Fig. 11.—Example, Street Box.

The nature of the material in, and shape of, the frames of the iron covers were the outcome of some experience. Nothing is better than a wide rim to the frame, roughed to prevent slipping, filled in with fine Portland cement concrete, made with very hard material, and allowed some weeks to set. The bad ones—and I see there are some—were the result of the want of care and bad material. The wide rim provides spaces for letters indicating the ownership of the box.

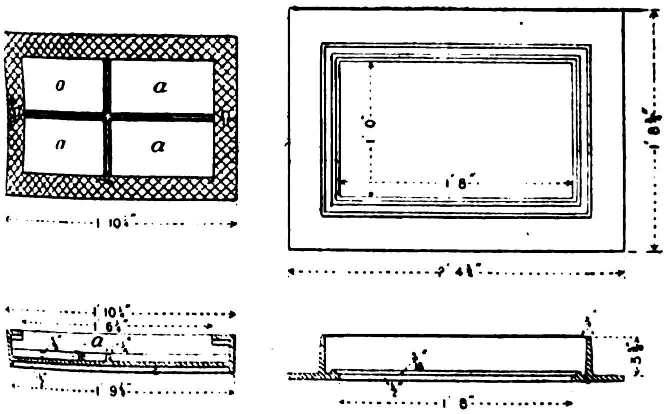

Fig. 12.—Example, Cover to Street Box.

In the trenches opened for that purpose all the conduits for conductors, the need for which in the future could be foreseen, had to be provided—(*a*) For the public lighting high-pressure conductors, concentric in some lengths, separate in others. (1¼in. pipes.) (*b*) For the private lighting primary high-pressure concentric conductors from the central to the converting stations, and between the latter. (2½in. pipes.) (*c*) For the three-wire feeding mains to points in the network. (Casing.) (*d*) For the three-wire distributing low-pressure conductors of the network. (Casing.) (*e*) For the pilot or signal wires for the service of the Company—one in each trench. (*f*) For spares and the future use of telephone conductors—as many in some places as 23—as the probable future demand indicated.*

As an under-estimate of the number and size of these meant a waste later on, in having again to open the streets, and as an over-estimate would be also wasteful, it was imperative, as I have said, to make a careful study of the whole. This was done with an accuracy only diminished by the following :—(*a*) The number of existing lights that might be expected within a given number of years to be replaced by glow lamps. (*b*) The selection of the boundaries of the areas, and, approximately, of the points for the transforming stations. (*c*) The desirability, though not an essential, of arranging the areas so that the difference between the consumption in each should not be too great. To the difficulties in finding sites for stations, and to the unforeseen obstructions to be encountered underground generally, all these became subordinate.

Careful canvassing of the City in various typical blocks of buildings (a "block" meaning all buildings situated between the nearest streets which meet one another) showed that they might be roughly classified in three, and that the number of existing lights, or lamps, averaged as follows, per square yard of ground space, was—

——	Central.	Eastern.	Western.
First-class blocks, per square yard	0·254	0·275	About the
Second-class „ „	0·171	0·171	same as the
Third-class „ „	0·067	0·100	Central.

Another canvass led to the conclusion that the proportion of those existing lamps that might be expected to be replaced by glow lamps was—

In the first-class blocks	0·75
„ second-class „	0·50
„ third-class „	0·33

The above figures were applied, and the blocks being all classified, and grouped in areas, so that each area might, as has been stated, have approximately the same number of lamps, the following results were obtained ; and, although it will be very a long time before its general accuracy can be tested, I feel sure that, so far as the number of lamps is concerned, it is not very far from the truth, although the number of areas may vary very much from the estimate.

For the three districts the following figures were arrived at :—

Glow Lamps.

—	Eastern.	Central.	Western.	Total.
18 areas..........................	139,900	—	—	—
14 „	—	100,750	—	—
12 „	—	—	99,547	—
Total, 44 areas...	—	—	—	340,197

If these are 8-c.p. lamps of 33 watts, this will give a load at the lamp terminals of 11,226·5 kilowatts. With 96 per cent. in the transformers at full load (the efficiency specified under the contract), and 5 per cent. loss in the mains, primary and secondary,* the output of alternating current of the three stations—namely, 12,100 kilowatts—is not far short of 12,236 demand the maximum possible load, so that with 80 per cent. of the lamps alight there would be nearly 20 per cent. spare generating plant. If it may be assumed also that each 8-c.p. (33 watt) lamp uses 18 units =6,123,546, with 20 per cent. spare, the load-factor comes out =13·8.

The design of 44 converting points in those districts required that, including spares, each transformer station should have, on an average, 275 kilowatts capacity. The three first permanent sub-stations, the sites of which were secured by, and the structures designed by, myself, were :—(1) Pancras-lane (Bene't Sherehog), with space for transformers having a capacity of 450 kilowatts ; (2) Nicholas-lane (St. Thomas Acorn), with space for 480 kilowatts ; (3) Queen Victoria-street (St. Nicholas Cole Abbey). This is a double station, and has space for 648 kilowatts.

Of these, I only show the design of the first, it being situated under exceptionally difficult conditions. (*See* Plan No. 13, &c.)

Transformation.

As has been said, little progress could be made with the selection of sites for permanent transformer stations before July, 1891, as the general scheme, upon which their relative positions much depended, was still under consideration.

To distribute the current generated in the pioneer stations, three temporary transforming stations were improvised, viz., one in Queen Victoria-street, in the basement of No. 47 ; one in the basement of the Mansion House ; one in St. Swithin's-lane, under a restaurant. In no case were these suited to become afterwards permanent stations, both on account of size and circumstances of surroundings. In the transformers first delivered the secondary windings gave a pressure of 1-20th that of the primary ; and, as the current is delivered at an E.M.F. of about 2,050, and it had to be distributed in the three-wire mains with an initial pressure of about 205 volts, they had to be coupled two in series—an arrangement which would disappear with the delivery of the contract transformers.

* On this subject, from the point of view of the telephone service of London, I hope to be permitted to read a Paper before the Institution at a future date.

* It is quite certain that this ideal condition of efficiency can only be achieved when a completed system is at full work ; at lower loads it will often go down to 76 per cent.

Digitized by Google

It early became evident that the price, by way of rent, that would be demanded for adequate space in, and access to, existing buildings, was prohibitive in the more costly areas. For instance, in Lombard-street, where every square yard is said to be worth £1,000, it can readily be conceived that £500 a year was asked for a small room in the basement. With this in view it behoved us to look for what we required to the space under those portions accessible to the public, or not available for building purposes. Careful searching showed that many engineering and financial difficulties existed. For instance, at some points where there was evidently ample space below the surface a prohibitive price was asked for the means of access to it through private property; and, again, at many such points, space for access within the area used by the public could not be obtained, for various reasons of public convenience and safety. In time our attention was turned to the old City graveyards, and, after long negotiation with the parish

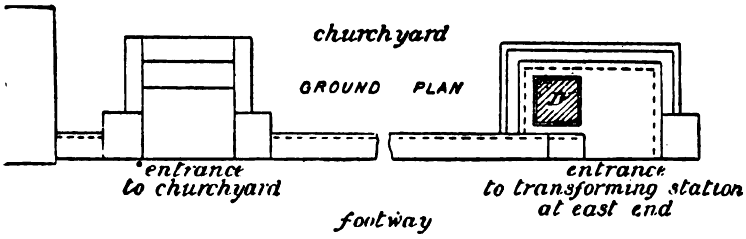

Fig. 13.

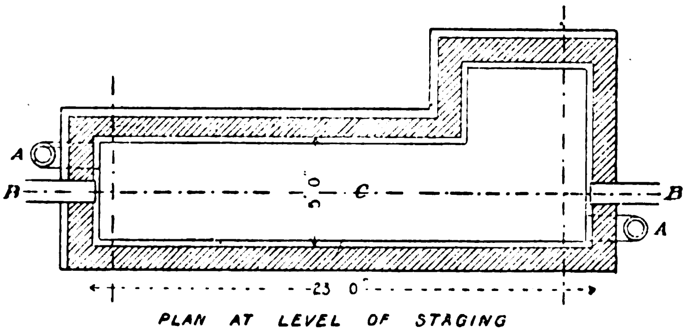

Fig, 14.

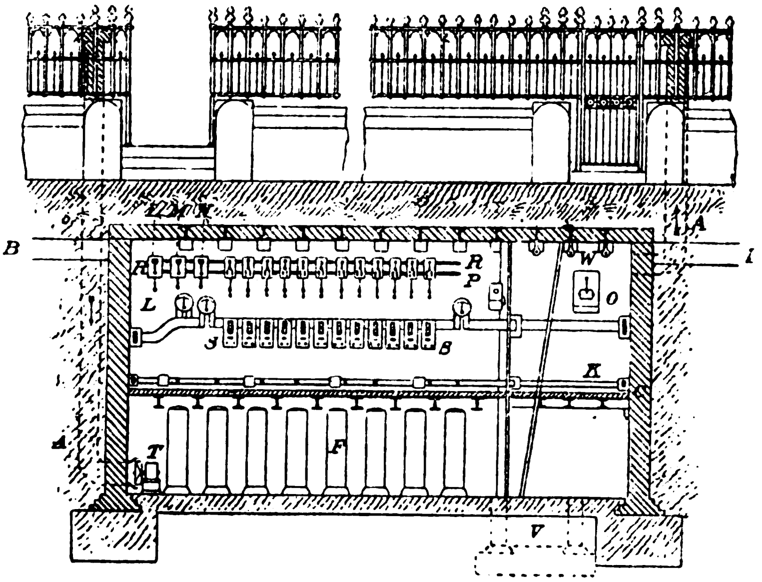

Fig. 15.

authorities, and with the Consistory Court and the Commissioners, leave was obtained at a fair cost to use a small portion of two of these open spaces in Pancras and Nicholas-lanes, so as to provide shafts for descent to the contiguous chambers to be constructed by leave of the Commissioners under the foot or roadways. But, even with this facility, the space below was in one case—namely, Pancras-lane—extremely limited, through the existence of large main sewers and water and gas pipes. In excavating, large quantities of human bones were met with, which had all to be transported carefully for extramural re-burial.

The drawings show the structure and the conditions of housing the transformers and switch-boards and connections. Under such circumstances every inch was important, and it was to the suggestion of my chief assistant, Mr. Nisbett, that the plan of placing

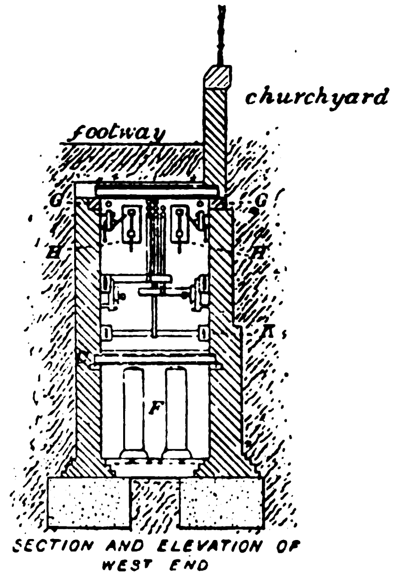

Fig. 16.

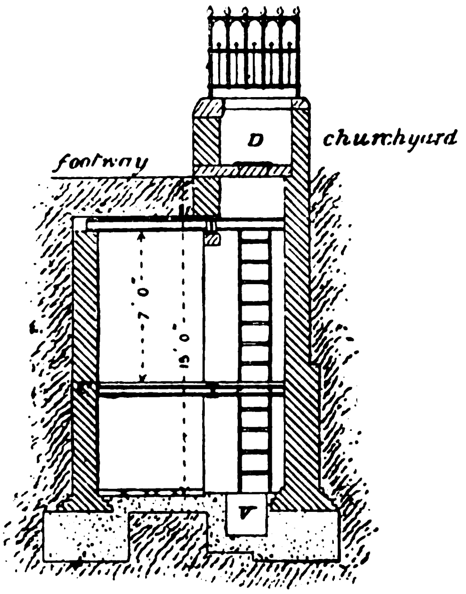

Fig. 17.

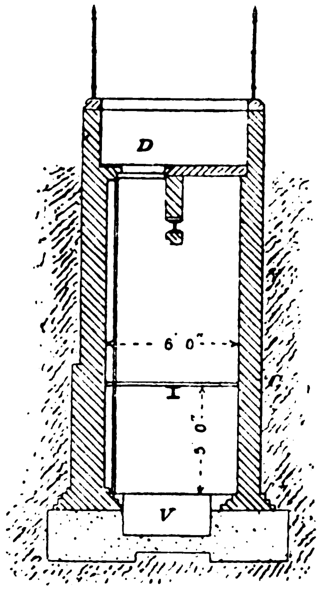

Fig. 18.

the transformers, F, below the floor was adopted in that station. Height was the most elastic dimension, and it will be seen that

the attendant standing over the transformers on a stage, C, has sufficient headway to stand up and attend to the board, S, one on the north, another on the south side. The floor of this stage is made of wooden squares, each of which can be taken off independently, and the top end of the transformer underneath exposed. When required to be removed, it is lifted by tackle suspended to a ring (as at W) in the arched roof, and being received on to a hand truck, it is moved along the floor to the bottom of the entrance shaft, and there, by other tackle, carried by a tripod standing above on the dwarf walls, lifted up to the surface, where it can be lowered on to a suitable trolley and taken away.

B (Figs. 14 and 15) shows where the conduits enter the station at the east and west ends.

D (Figs. 17 and 18) is the entrance for access to the descent by ladder into the staging.

F (Figs. 15 and 16) indicates the 18-kilowatt transformers.

G (Fig. 16) the position of the primary 'bus bars on each side.

H (Fig. 16) the main primary switches.

K (Fig. 16) the low-tension middle bar which runs round the tension.

L and N (Fig. 15) are switches for connecting at high tension with other transforming stations.

M (Fig. 15), a switch to divide the station in two for repairs.

O (Fig. 15), a recording voltmeter.

P (Fig. 15), the telephone to the generating station.

R (Fig. 15), one pole of high-tension bar, with a switch to every two transformers, and Brush-Mordey fuses.

S (Fig. 15), low-tension switches on 'bus bar, with a switch to every two transformers, and separate fuses.

T (Fig. 15), motor and fan for ventilation.

Drainage by a sump, V (Fig. 15), and ventilation by large upcast and downcast shafts, A A (Fig. 15), are provided, as well as means of telephonic communication, P. The cost of the builder's part of the structure, when completed, is about £430, with an annual charge for the way-leave of about £5. The honeycomb space under the staging floor should be able to receive 45 10-kilowatt transformers, of which 40 may be assumed to be in full use, the rest spare. The cost may be considered inthe following way:—

The present value of £5 a year for 21 years, at 5 per cent.	£64
Cost of building construction	430
„ transformers and fittings, as per contract	...
400 kilowatts, at £7 per kilowatt	2,800
Add 5 per cent. for supervision and contingencies	182
Total cost of a transforming station (having a maximum space for 450 kilowatts)	£3,476

To arrive at the capital of cost of the plant between the generating stations and the low-pressure feeders, it is necessary to add the cost of two concentric mains; and this I have taken from a table that I prepared which enables me to appropriate with very fair accuracy between the conduits for various purposes the cost of the underground work.

In this case the distance is about 1,200 yards.

Carried down	£3,476
Two 2½-in. wrought-iron conduits, at 4s. 4d. per yard	520
Two 0·154-in. concentric high-insulation 1,200-yard cables drawn in and connected	1,150
These figures give a total Capital outlay of	£5,146,

which will be repaid, interest and principal, at 4 per cent. in 21 years by, per annum, £161; to which should be added at least 2½ per cent. depreciation and repairs—say £136—and £70 for attendance and small stores: total, £367. Again, assuming a total consumption of about 18 units per 33-watt lamp fixed, and 12s. the gross earnings per lamp per annum, and allowing 96 per cent. efficiency as before, and the equivalent of 15,000 8-c.p. lamps connected with this one station, or say £9,000 per annum, the above annual charge will represent 4 per cent., being a standing charge on every unit sold.*

* A useful comparison may be drawn between the cost of these 2,000-volt mains and low-tension mains at 200 volts from the generating station to the same distributing centre. A loss of 2 per cent. in the high-pressure mains, and of 4 per cent in transforming—total, 6 per cent.—in the former, may be fairly balanced by a loss of 15 per cent. in the latter. The additional size of the low-tension plant is counterbalanced by its lower price. The low-tension main, required to carry 400 kilowatts at 200 volts pressure through 1,200 yards of distance with a loss of 15 per cent., would be about 4 square inches of copper in each outer conductor, and 2 square inches in the middle wire. Such a line, using the largest insulated cables made, and drawing them into 10 3in. "ways" of casing, would cost more than £15,660, representing an annual charge of £490, or 5·4 per cent. on each unit sold. Mr. Crompton will, I hope, give us the cost of the same sections of bare copper strip laid in culverts on his system, if he can keep his culvert within 160 inches sectional area.

(To be concluded.)

MEASUREMENT OF THE CAPACITY OF CONDENSERS UNDER ALTERNATE CURRENTS.*

BY J. SAHULKA.

The author has found that condensers having a solid dielectric have a smaller capacity when used with alternating currents than is given by a measurement by direct-current methods. He considers that the reason for this phenomenon lies in the construction of the dielectric. Even if it has a very high electrical resistance it absorbs energy in the process of charging, which energy is partly returned to the circuit in the discharge and partly converted into heat; for this reason, if a measurement of charge or discharge is made the galvanometer deflection is too high, for it is a measure not only of the quantity of electricity passing on to or out of the coatings, but also of that taken up or returned by the dielectric. Now it is well known that the dielectric takes an appreciable time to take up this quantity of electricity, and since in alternate-current working charge and discharge occur successively with enormous rapidity, it follows that the dielectric has not time at every charge to take up as much electrical energy as it would on direct currents measured by a galvanometer of a period perhaps a couple of hundred times as long, and similarly it gives up less energy in the discharge. This explains completely the difference in capacity for alternating and direct currents. It is necessary, then, says the author, to define what is meant by capacity, where alternating currents are concerned, and he proposes the following definitions. The capacity of a condenser in an alternate current circuit is equal to the reciprocal of the product of $2\pi n$ and its inductive resistance, the latter being equal to the quotient of the potential difference at the condenser terminals caused by the charge, divided by the strength of the current flowing into it.

The author mentions an experiment on a condenser with paraffined paper as dielectric, having a capacity of about a microfarad when measured on direct currents, which was found on an average of several experiments with alternate currents to have a capacity about 14 per cent. lower. Steinmetz's law, according to which condensers having solid dielectrics should absorb under alternating currents an amount of energy proportional to the square of the potential difference within a large range, was found by the author's experiments to be very approximately true.

* Abstract of article in Wiener Sitz.-Ber., Vol. 102.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, February 23rd.

PHYSICAL SOCIETY.

5 p.m. The following Papers are down to be read: (1) "A Method of determining Refraction Indices," by W. Littlewood. (2) "A New Electrical Theorem," by T. H. Blakesley. (3) "The Attachment of Quartz Fibres," by Prof. C. V. Boys.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting at 25, Gt. George-street. The following Paper is down to be read: "Ship Slipways," having special reference to the Dover Slipway, by Walter Beer, Stud.Inst.C.E.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Ladies' Night. Concert at the St. James' Hall Restaurant (Banquet Room), Regent-street, W.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Transformations of Electric Currents," by Prof. Silvanus P. Thompson, F.R.S.

SATURDAY, February 24th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture on "Light," with special reference to the Optical Discoveries of Newton, by the Rt. Hon. Lord Rayleigh, F.R.S.

TUESDAY, February 27th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be read, with a view to discussion: (1) "The Liverpool Overhead Railway," by J. H. Greathead and Francis Fox, M.M.Inst.C.E.; (2) "The Electrical Equipment of the Liverpool Overhead Railway," by Thomas Parker, M.Inst.C.E.

WEDNESDAY, February 28th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. The following Paper to be read: "Rainfall Records in the British Isles," by G. J. Symons, F.R.S.

FRIDAY, March 2nd. INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting at 25, Gt. George-street. The following Paper will be read: "Efficiency and Economy of Elevators," by Herbert W. Umney, Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Theory of the Cochlea and Inner Ear," by Prof. John G. McKendrick, M.D.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing, and Printing Offices :
1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.
Telephone No. 2714. Telegrams : "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies :—

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
  VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
  VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.
  The same book in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 8s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRIC MOTIVE POWER. By A. T. SNELL. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

PRACTICAL MAGNETISM. By J. A. KINGDON. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

rice: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

STEEL-PLATE PORTRAITS

Of Willoughby Smith; W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday; Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; and Mr. Alexander Siemens, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Piller or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

NOW READY.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK FOR 1894.

(THE BIG BLUE BOOK.)

1,000 pages of valuable information; 550 closely-printed pages of Directory matter.

Price 7/6, post free 8/3; abroad 8/10.

STREET LIGHTING.

Street lighting by glow lamps must be accepted as one of the problems of the near future, and it has been rather hastily assumed that if electric lighting by this means is superior to gas for some purposes it can replace it under nearly all circumstances. General WEBBER's remarks on this subject in his recent Paper on the lighting of the City of London seemed to have been interpreted by some of his hearers to imply that such a mode of street lighting is impracticable, but he did nothing more than give a warning against badly designed plans. In his Paper at the Society of Arts last week, Prof. H. ROBINSON observed that it is often stated that the cost of public lighting by electricity is greater than by gas, but that if the same standard of illumination had to be obtained by gas as by electricity the statement would not hold good. He thought that it was entirely a question as to whether or no the standard of lighting does not require to be raised. This is equivalent to stating

Digitized by Google

that to light a street with glow lamps at the ordinary degree of illumination is more expensive than with gas. Under ordinary circumstances this is undoubtedly true, and as a starting point it is necessary to inquire at what point the cost of the two systems is the same, and then the effect of an increase of the illumination on the cost of each system.

Among the gas burners of which we published tests some three months ago, were several burners used for street lamps, and of these one of the best known gave results almost exactly identical with the mean of 22 burners. The mean cost of lighting, as deduced from the report, was 22·8d. per candle per year, at four hours a day, this being the basis assumed by Prof. AYRTON in his Royal Institution discourse. We showed, on page 143 of our issue for December 8, 1892, that the cost of a 16-c.p. glow lamp, at 3 watts per candle, renewals at 6s. for 1,460 hours, and current at 4d. per unit, comes to 22·02d., or almost exactly the same as gas. We have given a very liberal figure for renewals, as we have no definite information on the subject. Whatever be the total number of hours of lighting in the year, or the number of lamps used for a mile of streets, this equality between the cost of gas and the cost of electric light will be maintained. To provide and maintain special mains and switches would, of course, far exceed the cost of a lamplighter, and the only difference would be a slight, but hardly appreciable, saving in cleaning. Where electric supply can be provided at a profit for less than 4d. per unit, and where gas is 2s. 6d. per thousand, or in this proportion, competition with gas becomes practicable. To attempt to reduce the lamp renewals by increasing the candle-power, and decreasing the number of lamps, although a very useful expedient in the case of large halls or public buildings, would only aggravate the bad distribution of the light in street work.

The extent to which uniform distribution of illumination for street lighting is necessary, convenient, or agreeable, is very difficult to decide. It is possible both by experiment to determine, and by calculation to predetermine, the distribution of illumination due to any given arrangement of lights, but these results, after all, tell us nothing. It is necessary to go to the street thus lighted, and to form a judgment of the quality of the illumination; and it is difficult to separate this from the intensity of illumination or total quantity of light. It has been found that the arc lighting in the City of London is less uniform than the gas lighting in Whitehall. If 100 square yards of each of these streets be divided into the best lighted 25 square yards, the worst lighted 25 square yards, and 50 square yards of mean illumination, the first and last of these are best provided in the City, but the 50 square yards of mean illumination are better in Whitehall. Two years ago, perhaps, before the City lighting had settled down, and while the lamps and perhaps the carbons allowed room for improvement, the illumination just after a lamp had fed was often considerably below the Whitehall standard. The City lamps cost £26 a year, and illuminate from 90 to 100 square yards. The gas lamps in Whitehall light between 10 and 11 square yards for one cubic foot of gas. There is a special contract for the Whitehall and Parliament-street lighting, the cost being £307 17s. 10d. per annum for the district lighted by the 45 special Sugg's lamps, the light being reduced after midnight. But at 3s. per thousand cubic feet the cost of lighting 1,000 square yards in this fashion would be about 2·7d. per hour. Taking 4,400 hours to the year, which is probably under the mark, arc lighting at the City rate would cost about 1·62d. for the same work. Taking these arcs at 500 watts (probably above the mark) the cost per unit is about 2¾d. per unit; this includes carbons and trimming. This low price is of course exceptional. From the very beginning of negotiations for lighting the City the obligation to carry out the street lighting was the condition on which the supply for private lighting would be granted. This price is probably little more than the "sheer cost" of the lighting. Allowing half a watt per candle for an arc, a very liberal allowance, and three watts per candle for a glow lamp, and setting carbons against lamp renewals, and trimming against lamp lighting, the cost of the latter is, roughly, six times that of the former, light for light.

We do not believe that the total light remaining the same, a really uniform distribution of light like moonlight would be appreciated, for the mean illumination would be on the whole less convenient than occasional well-lighted spaces separated by darker portions. We should not like our meals in ten-minute mouthfuls 144 times a day. But this question of distribution becomes very important when a rather lower standard of illumination than that of the City lighting is attempted. Only two remedies are possible, optical devices, or smaller and more numerous lamps. The former are unsatisfactory on account of the trouble and expense of cleaning the prisms, but we do not think that the latter has been given a fair trial. Six ampere, or even five ampere lamps, with a positive carbon as large as can be used without tunnelling or burrowing of the crater, and long negative carbons as slender as can be carried and handled without breakage, run in series of five on the outer conductors of a three-wire system have yet to be tried on a fairly large scale. The lighting of the City being confessedly better than that which most Corporations or Vestries could afford, the decreased illumination might with advantage be obtained by using such lamps on posts as high, or nearly as high as those in the City, and placed as far, or nearly as far apart. The glass might be less obscured, as the lights would be less dazzling. We should like to find some grounds for recommending the adoption of street lighting by glow lamps at a price profitable to the contractor, but even with the great saving of copper by a well-designed series system, running up to, say, 800 lamps on a circuit, the sixfold decrease of efficiency is a serious drawback. It is, however, as we have said, a problem of the near future, and the adoption of electric lighting by municipal authorities will afford many opportunities for experiment in this direction.

REVIEWS.

A Text-Book of Electro-magnetism and the Construction of Dynamos. Vol. I. By DUGALD C. JACKSON, B.S. (New York and London: Macmillan and Co., 1893).

This book makes no claim to special originality; it is a compilation from the works of Ewing, Hopkinson, and S. P. Thompson, in which it is sought to present in a condensed form the researches of these scientists on electro-magnetism and the theory of the dynamo. The present volume, which deals with continuous-current machines, is to be supplemented by a second volume in which alternators will be discussed. The standard of mathematical treatment in this work is too advanced, not to say prolix, for it to be of much value to elementary students; while, for advanced students and engineers, the treatment is on the one hand too abridged and on the other hand too unpractical and *doctrinaire*. The author has made the mistake of selecting a purely elementary scope, and subjecting it to very complicated treatment. For example, in Chapter V., on "The Magnetic Circuit of the Dynamo," instead of finding something which the beginner might understand or the engineer profit by, we discover such pure pedantry as the determination of the magnetic reluctance between two

parallel cylinders, one cylinder being supposed to be at one uniform magnetic potential and the other cylinder being supposed to be at another uniform magnetic potential, and no poles, yokes, or disturbing masses of iron being assumed to be within any less than an infinite distance. Now all this may be very interesting to the abstract mind with a taste for problem involving Laplacian and other functions; but, we need scarcely say, it is utterly useless from the dynamo point of view. Again, wherein lies the benefit in entering on a complicated series of armature calculations, on pages 113 to 121, based on purely abstract assumptions, if we are to be told at the end of it all that "this is an unwieldy method of determining the relations . . . and would usually give results of little value"? Unwieldy, indeed! but it is all the reader is offered.

We are informed in the preface that the book "treats the subject from the American standpoint and represents American practice." Yet we fancy that both American and English dynamo builders will be astonished to learn, on page 110, that the limit of safe current density in ventilated armature conductors is not greater than "about 2,500 amperes per square inch." This may be safe practice, but it is certainly not the safe limit. In the account of Hopkinson's magnetometer it is suggested that, instead of cutting the test piece in two and separating the parts under constant magnetic force, the magnetising current should be reversed, as in the Rowland's ring, "in which case the test piece need not be divided." This would be to defeat the whole purpose of the Hopkinson magnetometer, and to introduce the error which is inseparable from the Rowland ring method as recommended by the author.

The book seems to have been printed in America, and the illustrations are numerous, instructive, and very well executed, consisting as they largely do of curves showing various electromagnetic properties. But the book is not a safe one in the hands of any person who does not thoroughly understand all that it attempts to teach.

Theoretical Elements of Electro-Dynamic Machinery, Vol. I. By A. E. Kennelly. (London: E. and F. N. Spon. New York: D. Van Nostrand Co. 1893.)

This volume is a collection of a series of articles recently published in the *Electrical Engineer* of New York.

It professes to set forth, for students of electrical engineering, "the applied or arithmetical theory of electro-magnetism, as distinguished from the purely mathematical theory." It is difficult, and it would be manifestly unfair, to pronounce a final judgment on a treatise solely upon the evidence of the first volume. And this difficulty is rendered much greater when one is kept in ignorance of whether the complete treatise is to appear in two or two hundred volumes, and as to the scope of the whole work in relation to the "groundwork" which is "completed within the limits of these covers." Judging tentatively, then, we can only pronounce an opinion on the groundwork before us. And we are obliged to confess that it is disappointing. To us it seems that the author has abandoned entirely "the applied or arithmetical theory," and has given himself over to a series of elaborate discussions of the mathematical niceties of hypothetical and unpractical problems. Diagrams of equi-potential lines and of lines of force, in the neighbourhood of points, thin plates, bars, infinitely isolated circular currents, &c., &c., pervade the book, and are sandwiched between mathematical discussions of their conditions. Thus, for example, the most elaborate set of curves in the whole volume, namely that occurring on the plate between pages 80 and 81, represents the conditions of stress and of rate of change of stress when little iron spheres are suspended in various magnetic fields. All these things are instructive, useful, and interesting in their proper relation; and, though we might perhaps prefer a more elegant mathematical treatment than Mr. Kennelly has adopted, we feel that the volume would be a very good one in the hands of the purely scientific student. But it is surely a little out of place to offer a work of this kind to the electrical engineer, as a treatise on the theoretical elements underlying his machinery. In any work dealing with the theory or practice of machinery of any sort, imaginary and unpractical cases are only admissible when the argument based on them leads to some really practical conclusion which could not as well have been deduced from the consideration of truly practical cases. But perhaps Mr. Kennelly means to come down to the practical level in the sequel.

Electricity in the Service of Man. By R. Wormell, D.Sc. M.A. Third edition. Revised and enlarged by R. M. Walmsley D.Sc. (London: Cassell and Co. 1893.)

This popular treatise on the applications of electricity to the fulfilment of some of the numerous needs of mankind was originally a translation from the German of Dr. Von Urbanitzky. Since the issue of the first edition, however, the work has undergone a process of such extension and alteration that it may practically be regarded as having little in common with its German embryo. In Dr. Walmsley's hands, this latest edition has been brought well up to date, having been stocked with a vast amount of new and well-illustrated matter, dealing with recent advances in electrical engineering and technology. A great amount of obsolete matter has been removed, in order to make room for this new material, in spite of which the volume has now expanded to one of nearly a thousand pages, illustrated by an almost equally large number of popular pictures. We cannot, of course, recommend this work as in any way supplying the needs of a student of electrical science; neither, we are sure, would its translator and reviser expect us to do so. But, taken as a clearly-written, popular *exposé* of the development and present state of every important branch of electrical technology, it is an admirable production. We notice, however, with regret that among the things which have been cleared away from the original matter is the "Introduction" which was written for the first edition by Prof. John Perry, and which formed a very valuable introduction indeed, and which it was a pity to part with.

Elementary Manual of Magnetism and Electricity. By Prof. Andrew Jamieson, M.I.C.E. Third edition. (London: C. Griffin and Co. 1894.)

This manual has been written expressly for elementary or "first-year" students. It is designed to cover the requirements for examination in the elementary stage by the Science and Art Department. We may say, however, that the ground covered is more extensive, more practical, and less hampered by obsolete phrases than the official syllabus and examinations of that examining body. This is the third edition of Prof. Jamieson's useful little work, and we find that in many places it has been brought up to date. The matter is arranged in the form of a course of some 28 lectures; though we fancy that the majority of elementary classes would require to take their instruction in smaller and more numerous doses. It is always to be regretted when a lecturer and author allows the local phraseology of his lecture-room to be introduced into his text-book. What benefit, for example, can the general reader be expected to derive from the concluding sentence in this book:—"When we commence our Advanced Series of Lectures we will reverse the order of treatment. . . because it will be fresh in your memory. . . There is not the same excuse for avoiding the November fogs, because in the Advanced Course the treatment is of necessity more mathematical!" Why is the prospect of an advanced treatise to be advertised as a reversal of the elementary one, and what is the cause why a "mathematical treatment" in it is to be considered an antidote to the dread November fog? Careful reading of the proof sheets is the best antidote to this unnecessary type of literature. Nevertheless, we can strongly recommend Prof. Jamieson's little book to elementary students of electricity, who will find it a safe guide and an intelligible instructor.

A Pocket-Book of Electrical Rules and Tables. By John Munro, C.E., and Andrew Jamieson, M.I.C.E. Tenth edition. (London: C. Griffin and Co. 1894.)

This well-known pocket-book, which has been for so many years appreciated by every branch of the electrical profession, has now reached its tenth edition. In its latest form it resembles its predecessors, both in shape and size; but care has been exercised in careful revision of its contents and in the choice of new material. The additional features in this latest edition are:—An abstract of the decisions of the International Congress of Electrical Engineers at Chicago in

Digitized by Google

1893, in regard to nomenclature and units; Lloyd's rules for ship lighting; several tables of constants for electrical properties of copper, &c.; besides descriptions of some of the latest methods of electrical testing. In a work of this sort, which appeals to so many branches of a widely-extended technical science, it is inevitable that each branch will find much that it fails to see the direct use of; so that we are prepared to admit that complaints of the inutility of any part of the work may arise from shortness of sight. Still, we do not quite perceive any advantage in the retention of, say, the three or four whole pages devoted to a description of the secohmmeter—an instrument which has not only been robbed of its purpose, but also of half its name.

Annuaire pour l'An 1894, publié par le Bureau des Longitudes. (Paris: Gauthier-Villars et Fils.)

In addition to the usual astronomical, physical, chemical, electrical, magnetic, and geographical data the Annuaire for 1894 contains an interesting note by M. Poincaré, entitled "Light and Electricity according to Maxwell and Hertz," in which it is pointed out that Hertz's brilliant success in what M. Poincaré terms his "veritable synthesis of light," was due to the simple fact that he succeeded in his oscillator in devising an electrical starter of electromagnetic vibrations. At the end of his notice M. Poincaré calls attention to the various points connected with the Maxwellian theory that still refuse to submit to experimental proof; such, for instance, as the obstinate non-compliance of transparent bodies with the Specific Inductive Capacity = $\sqrt{\text{Index of Refraction}}$ law. Admiral Fleuriais contributes a note on the compass, M. Janssen one on his four days spent at the top of Mont Blanc, and the volume concludes with the speeches delivered on the occasion of the unveiling of Arago's statue in June last. It is a pity, however, that no room was found amongst the 800 pages of the Annuaire to put on record the decisions of the Chicago Electrical Congress; they were surely sufficiently mature to find a place even in a semi-official publication.

Laxton's Price Book, 1894. (London: Kelly and Co.)

Three sections of this annual publication are this year devoted to electrical matters. Two pages are devoted to lightning conductors; solid copper tape being, as was the case last year, recommended as the best form of conductor. Telephones take up a single page, occupied solely by the quotations of the Consolidated Telephone Company and the General Electric Company. The electric lighting section is far more extensive than last year, but is not on that account less likely to lead to misapprehensions. The labour of wading through a large number of price-lists and deducing a table of average prices would no doubt be severe, and the result perhaps not commensurate with the effort. But failing some such heroic device, the prices of at least half-a-dozen of the leading firms should be given in the case of each important piece of apparatus, so that the unsophisticated purchaser, for whom presumably such things as price books are compiled, may not have his attention too forcibly confined to a single or it may be to a couple of makers. A page is devoted to electric lighting engines: the names of plenty of makers are given in this case, it is true, but that of Willans and Robinson is omitted; perhaps it is too well known to require mention. Omissions of this kind are, however, as we have said before, likely to lead to misapprehensions.

Lockwood's Price Book, 1894. Edited by FRANCIS T. W. MILLER, A.R.I.B.A. (London: Crosby Lockwood and Son.)

This price book contains three sections devoted to electrical matters, viz., Lightning Conductors, Phœnix Rules, and Electric Lighting, the latter of which should prove fairly useful as a guide to an intending purchaser of electric lighting apparatus, the names and prices of several makers being given in the case of dynamos, arc lamps, glow lamps, and accumulators, whilst the prices of accessories are not taken from a single firm's catalogue, but are fairly average ones. Under the heading "Steam Engines for Dynamo Driving," however, the only engine given is that made by the Brush Company.

IMPROVED SWITCHES AND SWITCHING GEAR.

A number of switches and other appliances have lately been invented and patented by officers of the Brush Electrical Engineering Company. These inventions have for their object the simplification of central station working and the reduction of risk of accidental stoppages, which sometimes occur through carelessness or nervousness on the part of the attendants or from disablement of some part of the plant. Among these are automatic switching gear for continuous-current dynamos or exciters, interlocked switching gear for alternators working in parallel, interlocked switching gear for main feeders for continuous or alternate currents, return current fuse for use on the leads connecting an alternator with the omnibus bars, universal perfect contact switch, automatic transformer switch, automatic rocking gear for Brush dynamos, water type Brush automatic regulator. The first five of these are the invention of Mr. Raworth, the last is a modification of the Brush-Geipel regulator, and the remaining two are the invention of Mr. W. M. Mordey.

The return-current fuse is intended to render the parallel working of alternators perfectly safe, because the fuse will melt only with return current; that is to say, the fuse cannot be melted whilst energy is being transmitted from the alternator to the mains, but should the alternator from any cause fail to give its full volts the fuse will immediately act and cut it out of circuit. For instance, if three alternators be working in parallel, and one of them fail, then the other two have to supply current for the outer circuit, and sufficient additional current to burn the fuses of the disabled alternator. Under these conditions all the fuses would go

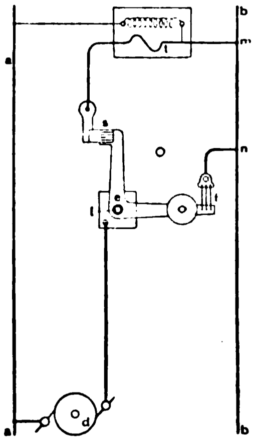

FIG. 1.—Diagram of Connections of the Return-Current Fuse.

simultaneously, or the fuses of the two working alternators might melt without cutting off the disabled alternator. Referring to the diagram (Fig. 1), *a* and *b* are the omnibus bars, *d* the alternator, *e* a weighted lever, *f* the fuse. The accelerator, which is a small transformer, is shown at *t*. It will be seen that the current enters at the joint, *l*, from which point there are two paths open to it to the omnibus bar, *b*—one through the switch, *s*, and the accelerator, *t*, and the other through the fuse, *f*. The accelerator has the effect of slightly increasing the pressure by something under half a volt, which is sufficient to induce the current to select that path in preference to the path by the fuse, but in the event of the current returning upon the alternator the accelerator acts as a retarder, and forces the current through the fuse, which as it melts liberates the switch, *s*, and cuts off the alternator.

The automatic switching gear, is applicable in all cases where two or more continuous-current dynamos or exciters are arranged to work in parallel on a common circuit. The switch closes automatically when the dynamo attains a voltage equal to that existing in the station mains, and opens automatically when the dynamo ceases to generate current. It is claimed that this automatic switching gear entirely prevents accidents from closing the switch when the dynamo is unexcited or not giving full volts; closing the switch when the polarity of dynamo is reversed; the current coming back on the dynamo and burning the fuses.

The interlocked switching gear is intended to facilitate the working of alternators in parallel; the gear is arranged so that the main switch cannot be closed until the field switch is closed and the field fully excited, also not until the synchroniser switch is closed. When the main switches are closed the field switch cannot be opened, and the main switches are locked by shutting off the synchroniser switch. The main switches break through water and oil, and are practically sparkless under all conditions. It is claimed that the interlocked switching gear prevents accidents from closing the main switch when the alternator is unexcited or not giving full volts; and from opening the field switch when the main switch is closed.

Digitized by Google

The interlocked switching gear for main feeders, continuous or alternating current, takes the form of a cast-iron pillar which carries the main switches, fuses, ammeter, and voltmeter, regulating gear, and interlocking machinery. In the base of the pillar, where the leads enter, there is a switch for disconnecting the upper part of the pillar and for establishing the circuit, in order that the instruments, fuses and switches may be examined and repaired without cutting off the feeder. There are three fuses fixed on the top of the pillar, any one of which may be put in circuit by turning the right-hand handle, but this handle cannot be moved unless the main switch be open. Double-pole switches are fixed below the fuses, and are actuated by the central handle, which is locked by a trigger, which must be released before the switch can be opened or closed. The handle on the left actuates the disconnecting switch, but it cannot be moved unless the main switch be open. By means of the disconnecting switch any part of the gear can be examined and repaired without any possibility of shock. It is claimed that no mistakes can be made, as the handles are all interlocked.

THE DRAFT ELECTRIC TRACTION REGULATIONS.—SUGGESTED ALTERATIONS.

Regulation observed upon.	Body making Observations and Observations made.
Definitions	**By Institution of Electrical Engineers.** In the last paragraph but one after ampere insert : The expression "line" or "lines" means an insulated conductor or conductors used for transmitting energy from the generator or generators to the trolley wire or other conductor from which the current is taken to the motor or motors by a rubbing contact. The expression "return" or "returns" means the conductor or conductors, uninsulated or otherwise, used for completing the circuit or circuits between the motor or motors and the generator or generators.
Definition 6.—The expression "current" means an electric current exceeding one-thousandth part of one ampere.	**By London Chamber of Commerce (Traction Committee).** The Committee understand that definition 6 is not intended by the Board to apply to telegraphic, telephonic, and railway signalling currents.
Reg. No. 1.—Any dynamo used as a generator shall be of such pattern and construction as to be capable of producing a steady continuous current.	The Committee suggest that the word "steady" in line 2 (*here* 6*), be defined under the heading "definitions."
Reg. No. 2.—One of the two conductors used for transmitting energy from the generator to the motors shall be in every case insulated throughout its length, and is hereinafter referred to as the "line"; the other may be insulated throughout, or may be uninsulated in such parts and to such extent as is provided in the following regulations, and is hereinafter referred to as the return.	**By Institution of Electrical Engineers.** Omit and insert in its place— The line or lines shall in every case be insulated throughout its or their length or lengths. The return or returns may be uninsulated in such parts or to such an extent as is provided in the following Regulations. **By London Chamber of Commerce (Traction Committee).** Line 2 (*here* 6).—It is suggested that the words "from earth" should be inserted after the word "insulated." **By Imperial Tramways Company, Limited.** "One of the two conductors used for transmitting energy from the generator to the motors shall be in every case insulated throughout its length, &c." It is gathered from the context of this Regulation that by "the two conductors" is meant the outward and the inward wire, only one of which transmits energy "*from* the generator *to* the motor," the other afterwards correctly described as "the return" carrying the current back to the generator. Apart from this use of the doubtful expression "two conductors," my Directors desire a clearer and more explicit statement of what is here meant by "insulated throughout its length." If by this is meant the use of "insulated wire" in its usual acceptation, then the Regulation is simply fatal to the use of the overhead trolley system, which can only be worked with an uncovered wire. If the words mean that at the points of support, and at the junction of the trolley wire-arm with the standard, complete and full insulation must be provided, then this should be made perfectly clear. And my Directors desire me to point out that if the other and fatal interpretation of the words be intended, then the Regulation is directly opposed to the opinion of the Joint Committee of the Houses of Parliament, 1893, as expressed in their Report, where the opinion is clearly stated that it is not for the interest of the public to insist upon regulations "calculated to retard" the development of electric traction.
Reg. No. 3.—Where any rails on which cars run or any conductors laid between such rails form any part of a return, such part may be uninsulated. All other returns or parts of a return shall be insulated.	**By Institution of Electrical Engineers.** Line 1 (*here* 4) after "between" insert "or contiguous to." Line 2 (*here* 7), after uninsulated" insert "but the supports of all overhead wires, whether line or return, shall be electrically connected to the return circuit." Line 3 (*here* 9), after "insulated" insert "unless of such sectional area as shall satisfy the Board of Trade." **By Association of Municipal Corporations (Dr. J. A. Fleming).** The uninsulated conductor is to be laid *between* the rails. It might be convenient to lay it just outside one of them. Hence it would be desirable to ask that this regulation may read—"between such rails, or within two feet of the outside of either rail." **By London Chamber of Commerce (Traction Committee).** Line 1 (*here* 4).—As it may be necessary in some cases to lay conductors outside the rails, it is suggested that the words "or contiguous to" should be inserted after the word "between." It is thought that the last sentence of this regulation will introduce a question on which it is impossible to give a definite opinion in the present state of knowledge. Any regulation forcing the industry to adopt a partially insulated return in place of an uninsulated one of heavier section may defeat the objects the Board of Trade have in view, and it is therefore suggested that the sentence should be omitted.
Reg. No. 4.—When any uninsulated conductor laid between the rails forms any part of a return, it shall be electrically connected to the rails at distances apart not exceeding 100 ft. by means of copper strips having a sectional area of at least one-sixteenth of a square inch, or by other means of equal conductivity.	**By Institution of Electrical Engineers.** In line 2 (*here* 7), after the word "rails" insert "to the satisfaction of the Board of Trade," and strike out remaining words. **By National Telephone Company.** The Telephone Company is satisfied that induction and not leakage is the main cause of disturbance, and that that disturbance will be minimised by requiring "the return," whether insulated or uninsulated, to be placed parallel, and as near as may be, to the line. *Regulation* 13 provides for this where the return is insulated, whether run overhead or underground. The National Telephone Company is advised that there is no reason (either electrical, engineering, or financial) why a similar regulation should not apply to the case of an uninsulated return. Obviously this is simple where the line and return are both underground, and where the line is overhead it is easy also to carry the *return* overhead and within a reasonable distance of the line, connecting the return at each post with the rails by means of suitable copper conductors. In most cases this return might suitably be carried on the poles which carry the line from which the feeders are supplied with energy. *Regulation* 4 provides for an electrical connection between an uninsulated conductor laid between the rails and forming part of the return and the rails themselves, at distances not exceeding 100 ft. It is suggested that this regulation should be modified, so as to provide for the same electrical connection with an uninsulated return carried overhead in the manner suggested above, and that the connections should be not more than 50 ft. apart, or if the distance of 100 ft. is maintained that the connections should be alternately to each rail, so that there should be a connection between one or other of the rails and the return every 50 ft.

* These references are to the numbers of the lines as printed in *The Electrician*.

Regulation observed upon.	Body making Observations and Observations made.

By London Chamber of Commerce (Traction Committee).

Line 1 (*here* 3).—It is suggested that this regulation should be amended in the terms suggested for No. 3, viz., by the insertion of the words "or contiguous to" after the word "between."

Reg. No. 5. — When any part of a return is uninsulated it shall be connected with the negative terminal of the generator, and in such case the negative terminal of the generator shall also be directly connected, through the current indicator hereinafter mentioned, to two separate earth connections which shall be placed not less than 20 yards apart.

Provided that in place of such two earth connections the Company may make one connection to a main for water supply of not less than four inches internal diameter, with the consent of the owner thereof.

Such earth connections shall be constructed, laid, and maintained, so as to secure contact with the general mass of earth, so that an electromotive force, not exceeding four volts, shall suffice to produce a current of at least two amperes from one earth connection to the other through the earth, and a test shall be made at least once in every month to ascertain whether this requirement is complied with.

Where any portion of either earth connection is placed within 6ft. of any pipe, and the Company are unable to obtain permission to metallically connect it with the earth connection, they shall provide by means of a non-conducting screen that no current can pass between the pipe and the earth connection, without traversing at least 6ft. of earth.

By Institution of Electrical Engineers.

First paragraph, last line, after "apart" insert "and close to the generator end of the uninsulated portion of the return."

Strike out paragraph 4 and bring down in its place paragraph 2.

By Association of Municipal Corporations (Dr. J. A. Fleming).

A more explicit definition should be asked for as to the nature of the "Non-Conducting Screen" which is to be provided in some cases. The regulation as it stands is difficult to interpret. The simple coating of the pipe with gas tar or pitch for 6ft. of its length might be asked for as a substitute for this "Non-Conducting Screen."

By Associated Railway Companies.

That an uniform system of joining up the generators be observed, whether the return wire be insulated or not, the object of this being to enable the block instruments to be joined up in such a manner that the traction current shall produce the "Train on Line" signal, and not the "Line Clear" signal.

By National Telephone Company.

Paragraph 3.—It is suggested that this paragraph should be re-cast, so that the test shall be the resistance of the earth measured in ohms, and that that resistance should not exceed one ohm.

By London Chamber of Commerce (Traction Committee).

Paragraph 2, line 2 (*here* 7).—That the diameter of the pipe be limited to "three inches" instead of "four."

Paragraph 3, line 1.—That the words "referred to in this clause" be inserted after the word "connections"; line 2 (*here* 4), that the word "electrical" be inserted after the word "secure."

Paragraph 4, line 3 (*here* 9).—It is suggested that all the words after "they shall" should be deleted, and that the following words should be substituted:—"if required by the owners, at their own expense coat such portions of the pipe as shall be within the distanceof 6ft. with a non-conducting 'material.'"

Reg. No. 6.—When the return is partly or entirely uninsulated the Company shall in the construction and maintenance of the tramway (*a*) separate the uninsulated return from the general mass of earth, and from any pipe in the vicinity; (*b*) connect together the several lengths of the rails; (*c*) adopt means for reducing the difference produced by the current between the potential of the uninsulated return at any one point and the potential of the uninsulated return at any other point; and (*d*) maintain the efficiency of the earth connections specified in the preceding Regulations, so as to fulfil the following conditions, viz.:—

(*i.*) That the current passing from the earth connections to the generator shall not at any time exceed 10 amperes.

(*ii.*) That if at any time and at any place a test be made by connecting a galvanometer or other current-indicator to the uninsulated return, and to any pipe in the vicinity, the direction of the current, if any, shall be from the return to the pipe, and not *vice versâ*.

(*iii.*) That under the conditions specified in (*ii.*) it shall always be possible to reverse the direction of the current by interposing a battery of three Leclanché cells connected in series.

In order to provide a continuous indication that the condition (*i.*) is complied with, the Company shall place in a conspicuous position a suitable, properly connected, and correctly marked current-indicator, and shall keep it connected during the whole time that the line is charged.

The owner of any pipe may require the Company to permit him to ascertain by test that the conditions (*ii.*) and (*iii.*) are complied with as regards his pipe.

By Institution of Electrical Engineers.

First paragraph, after (*a*) insert "so."

First paragraph, after (*b*) insert "so."

First paragraph, after (*c*) "adopt" insert "such."

First paragraph, after (*d*) insert "so."

First paragraph, line 8 (*here* 27), after "regulations" strike out word "so."

(*i.*) After "connections" insert "through the indicator"; strike out 10 amperes and insert "2 amperes per mile of single track without the consent of the Board of Trade."

(*ii.*) Strike out present clause, and insert "That if at any time and at any place a test be made by connecting a voltmeter to the uninsulated return, and to any pipe which the current can reach without traversing more than 6ft. of earth, the difference of potential arising from the working of the tramway between them shall not be greater than 4 volts if the return is positive to the pipe, or greater than one volt if the pipe is positive to the return."

(*iii.*) Strike out.

In last paragraph, line 1 (*here* 3), after "Company" strike out "to permit him"; in line 2 (*here* 4), after "that" strike out "the" and the s in conditions and "and (*iii.*) are" and insert "is"; and in the last line after "pipe" insert "and in the event of the test proving that the condition is complied with, he shall bear the cost of such test."

By Association of Municipal Corporations (Dr. J. A. Fleming).

Is a long regulation which reduces itself in effect to a provision that the Tramway Company must so far insulate the rails and uninsulated conductor that the integral earth leakage from all parts of the line back to the negative terminal of the generator shall never exceed 10 amperes, and that the uninsulated return, or partly insulated return, conductor shall be at a higher potential than any pipe in its neighbourhood by not more than four volts.

Since the pipe will always, or nearly always, be at zero potential, this is equivalent to saying that no point on the uninsulated rails or return conductor must be at more than four volts pressure above the earth under any conditions. I think that to carry out this regulation in practice over tramways of perhaps several miles in length will involve an expenditure in copper which may prove to require an unremunerative capital outlay. It must be borne in mind that in electric tramway working there arise occasionally demands for current far in excess of the normal working current, as, for instance, when a number of cars get stopped close together and have all to be started at once. Under these conditions the return line and feeders would be called upon to carry an abnormal current, and both the total leakage current and the potential of the return would be temporarily increased. I think that this maximum permissible leakage current should bear some proportion to the length of the tramline, because a leakage current which would be great for a short line would be small for a long one. I suggest that the request should be made to have the whole of Regulation 6 so altered as to state in sub section (*i.*) of Regulation 6 that the *average* integral leakage current passing from the earth connections to the generator shall not exceed five amperes per mile of tramway worked. This average can always be measured by a self-integrating ampere-hour meter. Also that in sub-section (*iii.*) of Regulation 6 it shall be permissible to take the maximum potential, by which the uninsulated return is allowed to be raised above the earth, as that which obtains when the cars are all in motion at about equal distances along the line, and that under these conditions six volts shall be the limit of potential allowable.

By National Telephone Company.

(*i.*) Ten amperes is, it is submitted, an excessive current to be allowed from the earth connections to the generator. There is no practical difficulty in keeping this below *five* amperes.

London Chamber of Commerce (Traction Committee).

That the word "so" be introduced before the word "separate" in line 2 (*here* 7), before the word "connect" in line 4 (*here* 12). That the word "such" be introduced after the word "adopt" in line 4 (*here* 14), and that the word "so" be inserted before the word "maintain" in line 7 (*here* 23). That the word "so" be in consequence deleted in line 8 (*here* 27).

(*i.*) It is suggested that the current permissible should be 3 per cent. of the total current output of the station.

(*ii.*) and (*iii.*). That the following clause be substituted for these:—"That if at any time and at any place a test be made by connecting an indicator to the uninsulated return and to any pipe in the vicinity, it shall always be possible to reverse the normal direction of the current by interposing a battery of three Leclanché cells connected in series or in the reverse direction by interposing one Leclanché cell."

Paragraph 6.—Beginning "the owner of any pipe," line 1. That the words "at reasonabler times and intervals" be inserted afte the word "Company."

Regulation observed upon.	Body making Observations and Observations made.
	That in case such test shows the conditions have been complied with the owner of the pipe be required to pay the expenses incidental to the test. **By Imperial Tramways Company, Limited.** This regulation appears in its details to be unnecessarily complicated, and in the final provision, enabling an outside owner to apply tests to the works of the Tramway Company, it is distinctly objectionable. It has yet to be demonstrated that the conditions *i.*, *ii.*, and *iii.* are practicable in the sense of being applicable to all cases and under all circumstances. In this connection my Directors would point to condition VII., as laid down in the Report of the Joint Committee, where it is expressly stated that the danger of electrolysis has arisen from faulty construction, and that with improved methods of construction (such as are contemplated by this Company), the danger may be made "practically negligible," assuming this opinion to be well-founded, the draft regulation now under consideration appears to be to a large extent unnecessary.
Reg. No. 7.—When the return is partly or entirely uninsulated its electrical resistance shall be tested by the Company at least once in every three months. If at any such testing it appears that the resistance has increased by more than 15 per cent. above the value recorded at the time the tramway was opened, the Company shall take immediate steps to reduce the resistance to the said recorded value.	**By Institution of Electrical Engineers.** In line 3 (*here* 10), after "increased" insert "permanently"; and in line 6 (*here* 17), before "the said" insert "within 5 per cent. of." **By Association of Municipal Corporations (Dr. J. A. Fleming).** This regulation appears on consideration to be difficult to carry out in practice, because of the difficulty of separating the true resistance of the partly-insulated return from that of the earth in parallel with it, and which last may vary from day to day. It would be more difficult to determine if the uninsulated return is laid in separate sections, each connected with the generator by insulated feeders. A careful inspection by eye would be preferable to an uncertain electrical test. I should prefer to see this regulation modified so that it should state that the uninsulated return is to be carefully inspected once in three months, or oftener, and such tests applied as shall be sufficient to show that it is not in any way deteriorated. **By London Chamber of Commerce (Traction Committee).** That for Regulation 7 the following be substituted :—"When the return is partly or entirely uninsulated, a record shall be kept by the Company of the extreme difference of potential reached during the working of the tramway measured between the most distant part of the system and the nearest home point of the uninsulated portion of the system, and if this record shows that at any time the recorded difference of potential exceeds 15 per cent. above the value the company shall take immediate steps to reduce the difference to the required value."
Reg. No. 8.—Every electrical connection with any pipe shall be so arranged as to admit of easy inspection, and shall be tested by the Company at least once in every three months.	**By Institution of Electrical Engineers.** In line 2 (*here* 5), strike out "inspection" and insert "examination." **By London Chamber of Commerce (Traction Committee).** The Committee are desirous of knowing whether the intention is that a manhole should be placed at each electrical connection. The cost of such construction would be unduly heavy.
Reg. No. 9.—Every line and every insulated return or part of a return shall be constructed in sections not exceeding one half of a mile in length, and means shall be provided for isolating each such section for purposes of testing.	**By Institution of Electrical Engineers.** Strike out and substitute : "The insulation of the cables forming the line and the insulated portion of the returns shall be tested apart from all connections, joint boxes, test boxes, &c., and shall not be permitted to fall below the equivalent of 10 megohms for a length of one mile, and for the purpose of testing such insulation these lines and returns shall be so constructed that they can be divided into sections not exceeding one half mile in length, and these tests shall be made at least once every three months." **By Association of Municipal Corporations (Dr. J. A. Fleming).** Provides that the line and insulated return shall be laid in sections not exceeding one half mile in length. There is no reason to impose this limit on insulated feeders, and it would be advisable not to have them so limited. Hence a request should be made that this regulation shall not cover insulated feeders. **By London Chamber of Commerce (Traction Committee).** That the following be substituted for Regulations Nos. 9 and 11 :—"The insulation of the cables forming the line and the insulated portion of the returns shall be tested apart from all connections, joint boxes, test boxes, &c., and shall not be permitted to fall below the equivalent of 10 megohms for a length of one mile, and for the purpose of testing such insulation these lines and returns shall be so constructed that they can be divided into sections not exceeding one half mile in length, and these tests shall be made at least once in each quarter."
Reg. No. 10.—The insulation of the line and of the return when insulated, and of all feeders and other conductors, shall be so maintained that the leakage current shall not exceed one-hundredth of an ampere per mile of tramway. The leakage current shall be ascertained daily before or after the hours of running when the line is fully charged. If at any time it should be found that the leakage current exceeds one-tenth of an ampere per mile of tramway, the running of the cars shall be stopped until the leak has been localised and removed.	**By Institution of Electrical Engineers.** Strike out and substitute : "The insulation of the line of the insulated portion of the return when both are coupled up ready for work shall be such that the leakage current shall not exceed one-hundredth of an ampere per mile of tramway. The leakage current shall be ascertained daily before or after the hours of running when the line is fully charged, and if at any time it exceeds one-tenth of an ampere per mile, the leak shall be localised and removed as soon as practicable. Provided always that where both line and return are placed within a conduit these leakage tests shall not apply." **By Association of Municipal Corporations (Dr. J. A. Fleming).** The leakage current from all the parts of the circuit which is insulated is not to exceed one-hundredth of an ampere per mile. It appears to me that this is a difficult standard to attain in ordinary practice when working at, say, 500 volts on the line. It will be an impossible standard for bare conductors in a culvert. I think that at least one-twentieth of an ampere should be allowed, and the limit beyond which leakage should be considered great enough to stop working should be put at one ampere as a minimum per mile of tramway worked. **By London Chamber of Commerce (Traction Committee).** That the following be substituted for Regulation 10 : "The insulation of the line and of the insulated portion of the return when both are coupled up ready for work shall be such that the leakage current shall not exceed one-hundredth of an ampere per mile of tramway. The leakage current shall be ascertained daily before and after the hours of running, and if at any time it exceeds one-tenth of an ampere per mile, the leak shall be localised and removed as soon as practicable. Provided always that where both line and return are placed within a culvert no such leakage tests shall be required." **By Imperial Tramways Company (Limited).** The Directors would draw attention to the drastic provision in the last sentence of this proposed regulation. Even were it a just and politic provision, which cannot in the meantime be admitted, the absence of any provision of authority or process by which such interruption in the running of the cars is rendered possible indicates a want of thoroughness in the drafting of the regulations.
Reg. No. 11.—The insulation resistance of all lines, insulated returns, feeders, or other conductors, laid below the surface of the ground, shall not be permitted to fall below the equivalent of 10 megohms for a length of one mile. A test of the insulation	**By Institution of Electrical Engineers.** Strike out. **By Association of Municipal Corporations (Dr. J. A. Fleming).** Provides that the insulation of all conductors laid below the ground shall not fall below 10 megohms per mile. I think a request should be made to reduce this to one megohm per mile. **By London Chamber of Commerce (Traction Committee).** *See Reg. No.* 9.

Digitized by Google

Regulation observed upon.	Body making Observations and Observations made.
resistance of each part of the circuit shall be made at least once in each month.	
Reg. No. 12.—Where in any case in any part of the tramway the line is erected overhead and the return is laid on or under the ground, and where any wires have been erected or laid before the construction of the tramway in the same or nearly the same direction as such part of the tramway, the Company shall, if required so to do by the owners of such wires or any of them, permit such owners to insert and maintain in the Company's line one or more induction-coils or other apparatus for the purpose of preventing disturbance by electric induction.	**By Institution of Electrical Engineers.** In last line after "induction" insert: "Such apparatus to be approved by the Tramways Company subject to an appeal to the Board of Trade." **By Association of Municipal Corporations (Dr. J. A. Fleming).** This is a provision intended to prevent disturbance by induction on neighbouring wires. If these wires are telephone or telegraph wires, it is in accordance with the recommendations of the Joint Committee to ask that it shall be stated that the owners of such wires shall take such steps by the use of a metallic twisted return to guard themselves against inductive disturbance, and then, if unable to avoid it, shall be permitted to insert and maintain induction coils as stated in the Company's line. **By London Chamber of Commerce (Traction Committee).** Last line.—It is suggested after the word "induction" the following words be added, "provided nevertheless that the efficiency and cost of the line be not thereby affected." **By Imperial Tramways Company (Limited).** Even if the proposal here indicated were practically useful, my Directors would call special attention to this second introduction of a power of interference with a tramway company's installation plant and works on the part of irresponsible outsiders. As with the regulation already discussed, my Directors here notice the entire absence of any intervening public authority to protect the interests of a tramway company from unnecessary officious or malicious and interested interference. With reference to this regulation, my Directors would point out the absence of any provision for the erection of "guard wires" for the protection of the tramway electric line against accidents, contact, or interference by wires belonging to the telegraph, telephone, or other opposing interests. The interference with any existing wires on the part of a tramway company is fully safeguarded here and in regulation 14, but my Directors miss the insertion of any reciprocal obligation on the part of telephone or telegraph works yet to be erected. On this point it is submitted very careful consideration is required. **By London Chamber of Commerce (Traction Committee).** It is suggested that it is unnecessary to vary the distance permissible between the line and return in different systems.
Reg. No. 13.—Any insulated return shall be placed parallel to and at a distance not exceeding 3ft. from the line when the line and return are both erected overhead, or 18in. when they are both laid underground.	
Reg. No. 14.—In the disposition, connections, and working of feeders, the Company shall avoid injurious interference with any existing wires.	**By Institution of Electrical Engineers.** Strike out. **By Association of Municipal Corporations (Dr. J. A. Fleming).** As this regulation stands it would appear that the whole burden of avoiding inductive disturbance rests with the tramway companies. It would be in accordance with the recommendations of the Joint Committee to ask that this shall be modified to read as follows:—"In the dispositions, connections, and working of feeders the Company shall avoid injurious interference with any existing wires which cannot be prevented by the owners of these existing wires, providing a twisted metallic return for the circuits thus liable to be disturbed." **By London Chamber of Commerce (Traction Committee).** This regulation has had the most serious consideration at the hands of the Committee, and it is unanimously regarded by them as practically re opening points dealt with in the recommendations of the Joint Committee. It is felt that it is too general in its terms, and they would suggest its fuller definition or omission. **By Imperial Tramways Company (Limited).** The rule in its bald state as drafted may or may not be charged with deadly peril to the development of electric traction. In providing that "the (tramway) company *shall avoid* injurious interference," it is respectfully submitted that the draft regulation goes far beyond the condition proposed by the Joint Committee that the "undertakers shall *take all reasonable* precautions" not injuriously to affect existing works, and that the Board of Trade should have regard to expense involved and to the effect commercially of any rules proposed to be laid down. In its present bare condition this regulation appears to approve and enact all the extravagant demands of the telephone interest, which it was the express purpose and intention of the Joint Committee to restrain.
Reg. No. 15.—The Company shall so construct and maintain their system as to secure good contact between the motors and the line and return respectively, and they shall not allow sparking to occur at the rubbing or rolling contacts in any part.	**By Institution of Electrical Engineers.** In line 3 (*here* 8), after "allow" insert "more"; and in last line after "part" insert "than is considered reasonable by the Board of Trade." **By Association of Municipal Corporations (Dr. J. A. Fleming).** The word "unnecessary" should be inserted before "sparking." **By National Telephone Company.** Forbids in general terms sparking between the line and the trolley or between the wheels and the rails, but without specifying any precautions which are to be taken, and the tramway companies may contend that it is not possible always to prevent sparking at one or other of these contacts. It is suggested that the tramway company should be required to take all reasonable precautions by the use of brushes and other proper means to maintain effective and uniform contacts so as to minimise as far as practicable both sparking and irregular contacts at these points. **By London Chamber of Commerce (Traction Committee.** Line 3 (*here* 8).—It is suggested that this regulation, as well as No. 17, be merged together, and that the word "undue" be inserted after the word "allow" in the third (*here* 8) line of No. 15. **By Imperial Tramways Company, (Limited.)** The first paragraph of this regulation appears to be unnecessary, for unless good contact is secured the working will be almost impracticable and will certainly be unprofitable. The second part of the regulation, that sparking shall not be "allowed," is also superfluous, as a tramway company would never knowingly "allow" such a state of things to exist, although it can hardly be deemed reasonable or practicable that under all circumstances it should be rigidly prohibited. That this view is correct is proved by *Regulation* 17, in which a tramway company is required to "take all precautions to prevent the occurrence of *undue* sparking." On the rails, sparking is to be totally prohibited, or rather the company is forbidden to "allow" it, but in the generators and in the motors on the car, only "undue sparking" is to be "prevented" as far as "reasonable precautions" allow this to be done. The second part of Regulation 15 should, it is submitted, be deleted.
Reg. No. 16.—In working the cars the current shall be varied as required by means of a rheostat containing at least 20 sections, or by some other equally efficient method of gradually varying resistance.	**By Association of Municipal Corporations (Dr. J. A. Fleming).** The selection of 20 sections in the rheostat is perhaps somewhat too definite. What is really required is a means of varying the current continuously without sudden changes. It would be better to insist that the starting and stopping of cars shall be effected by a continuously varying resistance.
Reg. No. 17.—In the construction and use of their generator and motors the Company	Would disappear if Reg. No. 15 is revised as above.

Digitized by Google

Regulation observed upon.	Body making Observations and Observations made.
shall take all reasonable precautions to prevent the occurrence of undue sparking.	
Reg. No. 18.—Where the line or return, or both, are laid in a conduit the following conditions shall be complied with in the construction and maintenance of such conduit :— (*a*) The conduit shall be so constructed as to admit of easy inspection of, and access to, the conductors contained therein, and of all insulators and supports. (*b*) It shall be so constructed as to be readily cleared of accumulation of dust or other *débris*, and no such accumulation shall be permitted to remain. (*c*) It shall be laid to such falls, and so connected to sumps or other means of drainage, as to automatically clear itself of water without danger of the water at any time reaching the level of the conductors. (*d*) If the conduit is formed of metal, all separate lengths shall be so jointed as to secure metallic continuity for the passage of electric currents, and where the rails are used to form any part of the return they shall be electrically connected to the conduit by means of copper strips having a sectional area of at least one-sixteenth of a square inch, or other means of equal conductivity, at distances apart not exceeding 100ft. Where the return is wholly insulated and contained within the conduit the latter shall be connected to earth at the generating station through a high-resistance galvanometer suitable for the indication of any contact or partial contact of either the line or the return with the conduit. (*e*) If the conduit is formed of any non-metallic material not being of high insulating quality and impervious to moisture throughout, and is placed within 6 ft. of any pipe, a non-conducting screen shall be interposed between the conduit and the pipe, or such material and dimensions as shall provide that no current can pass between them without traversing at least 6 ft. of earth.	**By Institution of Electrical Engineers.** In (*a*), line 1 (*here* 3), strike out "inspection" and insert "examination"; and in last line before "supports" insert "their." In (*c*), line 3 (*here* 7), after "water," strike out "at any time." In (*d*), line 2 (*here* 5), after "secure," insert "efficient"; and strike out "passage of." In line 3 (*here* 7), after "currents," insert "which may pass through it"; strike out "and," and commence new sentence. "Where," &c. In line 4 (*here* 10), after "be," insert "equally efficiently"; and after "conduit" strike out down to "feet," and insert "to the satisfaction of the Board of Trade." (*e*) Strike out paragraph, and substitute: "The leakage current shall be ascertained daily before or after the hours of running, when the line is fully charged, and if at any time it shall be found to exceed half an ampere per mile of track the leak shall be localised and removed as soon as practicable." **By Association of Municipal Corporations (Dr. J. A. Fleming).** Is a comprehensive regulation for conduit systems. A more complete definition should be asked for as to the means of carrying into effect the sub-section (*e*), which requires a "Non-Conducting Screen" to be placed between a neighbouring pipe and a non-metallic partly insulating conduit. **By London Chamber of Commerce (Traction Committee).** (*a*) A definition is desired of what is meant by "easy inspection." (*d*) It is suggested that it does not seem satisfactory to electrically connect lengths of conduit together, especially where a complete metallic return is used, on the grounds that a fault might cause a complete breakdown in the whole system if metallic continuity was insisted on, instead of only a partial one. (*e*) The Committee would wish to have an indication from the Board as to what material they would consider would satisfy the requirements of this clause.
Reg. No. 19.—The Company shall, so far as may be applicable to their system of working, keep records as specified below. These records shall, if and when required, be forwarded for the information of the Board of Trade.	The question has been carefully considered, and the Committee have nothing to add beyond the suggestion that it might be difficult in small lines to afford the services of an electrician of efficient ability to make the daily and periodical tests required of sufficient accuracy to be of any value. **By Institution of Electrical Engineers.** Last line, add "s" to "Regulation," and after "10" insert "and 16 (*e*)."
Daily Records .... Leakage current (*vide* Reg. 10).	
Monthly Records......... Insulation resistance of different conductors (*vide* Reg. 11).	Strike out last line and transpose it to "Quarterly Records," after line 2.
Quarterly Records ...... Conductance of joints to pipes (*vide* Reg. 8).	Line 2, strike out "Conductance," and insert "Resistance," and bring down line 2 of Monthly Records.
Occasional Records ..... Any tests made under provisions of Reg. 6 (*ii.* and *iii.*).	Line 1, strike out "and iii."

Additional Proposals.

Proposed New Regulations.

By Institution of Electrical Engineers.

Numbered 17: In any case where overhead lines are used, the Company shall erect and maintain in good order a guard wire in such a manner as to prevent any previously erected wire or wires from coming into metallic contact with the conductors carrying the tramway current.

By Associated Railway Companies.

That the most effectual means of preventing interference with the railway wires will be found in laying the "line" and "return" traction wires on insulated supports within a metal culvert, the joints and the section of the said culvert being of such a character and section as shall ensure a perfect return to the generating station for the traction currents should such from defective insulation, or other causes, pass into it

That where an overhead wire or wires are used for conveying the current to the tramcar, the pillar, pillars, or other supports carrying such wire or wires shall be so connected electrically with the return circuit of the said tramway as to convey to it without loss any and all such current as may escape from the insulator or insulators by which the conducting wire or wires are attached to the said pillars or supports.

That where two overhead wires are employed, the one for the outgoing and the other for the return current, the supports for the same shall be so electrically connected that any current escaping from the one shall be conveyed to the other without any portion of the same passing to earth.

That where the route of the tramway is circuitous the return wire shall be aided by insulated feeders.

That having regard to the fact that any failure in the electrical conductivity of the traction conductors, culverts, poles, or brackets, &c., may prove the occasion of interference with neighbouring block signals, the wires of such block-signalling instruments should be dissociated from the earth as far as possible, and that in common justice the cost incurred by the railway companies in consequence of these or other precautionary measures, in order to provide as far as possible against the incursion of the traction currents, should be borne by the traction authority concerned.

By Gas Light and Coke Company.

We observe that the regulations proposed do not contain any prohibition forbidding connections with gas pipes, and also contain an express permission to use, in lieu of two earth connections to the negative terminal of the generator, one connection with a water main.

The Company venture to suggest the advisability of inserting such a prohibition as above referred to, and in support of this suggestion they desire to refer the Board to the evidence given before the Joint Committee of both Houses on Electric Powers (Protective Clauses) by Major Cardew, Sir Frederick Bramwell, Dr. J. Hopkinson, Prof. Dewar, and others, which, in the view thereof taken by the Company, entirely justifies, if it does not do more, such a prohibition; the Company also hope the Board will, at least as regards the Metropolis, reconsider the advisability of permitting connections to water mains, and would refer to the same evidence in support of this proposition. In the Metropolis the confusion existing between water mains and gas mains and other subterranean works in the street is so great and the propinquity between water mains and gas mains is so close that the electrical use of water mains inevitably carries with it the use of the gas mains, and consequently great danger to the public.

The Company desire further to place before the Board the necessity of treating the Metropolis differently to the extra-metropolitan parts of the country, and, in particular, that the use of uninsulated returns should be entirely prohibited in the Metropolis, excepting places where the Board of Trade should, after a full investigation of the special circumstances, see fit to sanction the use of such returns.

In many, if not in most, streets in the Metropolis the subsoil is crowded with mains and works of gas, water, electric, hydraulic, and other companies and of sewage authorities. Amongst other inconveniences, too obvious to need comment, this state of things carries with it a very great liability to frequent subsidences, the formation of cavities, sometimes of great extent, and frequent leakage of gas mains; these subsidences, cavities, and leakages are, for the most part indiscoverable and not to be prevented

Digitized by Google

by any possible precautions, and often are discovered only after injurious consequences have arisen; explosive mixtures are liable to be formed in these cavities and in sewers, particularly the numerous disused sewers, and frequently the gas travels long distances from the seat of the original mischief. Of these matters this Company has had only too frequent experience, as well as of the practical difficulty of coping with the dangers so created in an adequate and effective manner. The Company are, therefore, led to very earnestly deprecate the permitting of anything likely to intensify or increase the danger to persons or property in crowded centres, such as the Metropolis contains, and uninsulated or defective insulated conductors of electric currents cannot but be regarded, the Company are advised, as likely sources of danger. The Company desire to express the hope that the Board will take these observations into consideration, and reconsider the question of permitting uninsulated returns in the Metropolis.

The Company further observe that clauses (2 and 3) of the clauses to be inserted in all Bills and Provisional Orders limit the protections against injurious affection of gas and water mains, and the regulations to be made by the Board to fusion and electrolytic action. The Company venture to suggest the desirability of, in practice, extending the powers to provisions against other modes of injurious electric action. Clause 4 of these clauses imposes, in very sweeping terms, a single penalty, with a further daily penalty in case of a continued offence, for any breach of the Act, Order, or Regulations. The Company are advised that this clause would seem to defeat the object of the Joint Committee, inasmuch as unless the legal right to recover compensation in the shape of damages is expressly reserved to persons injured by the undertaker's acts, or neglects, the Courts might, on the authority of decided cases, hold that the sole remedy for, or consequence of, any breach of the Act, Order, or Regulation was the recovery of the penalty, and that the recovery of damages by an injured party was excluded. So that if the undertakers chose to risk the imposition of a penalty, and not necessarily the full penalty, they would enjoy a practical immunity and the most effectual deterrent, viz., the liability to suffer in damages would be excluded. The Company desire us to draw attention to this aspect of the clause with a view to the Board's future opportunities of action in the matter.

TELEGRAPHIC COMMUNICATION BETWEEN ENGLAND AND INDIA: ITS PRESENT CONDITION AND FUTURE DEVELOPMENT.

The following report of the discussion which followed the reading of Mr. E. O. Walker's Paper on the above subject before the Indian Section of the Society of Arts, on Thursday, the 8th inst., is taken from the last number of the *Journal of the Society of Arts*:—

Sir OWEN TUDOR BURNE, K.C.S.I., said that he was able, after a long official experience, to corroborate all that Mr. Walker had brought forward, as to the necessity for cheapening telegraph rates, and as to the quickness of communication between England and India, mentioning an instance, some years ago, of a telegram being despatched and a reply received within seven minutes.

Mr. MARTIN WOOD said the lecture of Mr. Walker afforded a comprehensive review of a truly Imperial subject, and, amongst other passages, he was glad to hear the references made in the Paper to the difficulties which some of the pioneers of telegraphic communication with the East had to go through. He remembered, for instance, the enthusiasm which the name of Col. Patrick Stewart always created among those who had been associated with him, and also some of Sir Charles Bright's staff in the Persian Gulf. He believed there was still a charge on the Indian revenue of about £18,000 a year for that early company, which only acted for about a week. He hoped some means would be found for relieving the taxpayers of India from that charge, though he did not know how this should be met, whether from future profits of Government lines, or what else, but it was too bad that India should be paying all these years, now nearly two lakhs and a-half, for no service whatever. He had been much interested in hearing the mention of the laying of the cable from Suez to Bombay, because it was his own fortune to be on board the "Great Eastern" when it was done, and as Captain Halpin, who then commanded that once noble vessel, had only recently died, it was only fitting to recall his memory. All on board the ship could testify to the great ability with which he carried out that important work. There was one practical object that might be furthered by the reading of this Paper, namely, some appreciable reduction in charges for telegrams to the East. This was no mere outside claim for cheapness, for Mr. Walker had shown good reasons for such reduction, based on his own intimate experience of the subject.

Mr. B. T. FFINCH said after this interesting and exhaustive Paper there was very little for him to add. With regard to the reduction of the tariff to India, he was not in a position to say what might eventually be done; but he knew the subject was one in which the Government of India took a great interest, and that they were constantly watching events. Tariffs were generally considered, and reduced or increased at the Telegraphic Conferences, which took place every five years. The next conference should have taken place next year, but had been postponed till 1896, so that he feared until it met no alteration could be expected. It must be remembered that the Eastern Telegraph Company had spent large sums of money on their line, and their capital was over £6,000,000. Submarine cables would not last for a very long period, especially when laid in such seas as the Red Sea and the Persian Gulf. Mr. Walker appeared to think that a land line was perhaps better than a submarine cable. It undoubtedly was cheaper; but it must be remembered that the land lines through a great part of the way between India and England traversed countries where there were no railways and no roads. The coast which extended 700 miles from Kurachi, was one of the most desolate and arid tracks of country in the whole world. When that line was first built, in 1862, the Beluchis were not so well known as they now are, and it was the object of the working parties to construct the line as near the sea as possible. They had the sea on the left hand and a range of mountains on the right, which eventually merged into the sea. As the line was being constructed they got nearer and nearer to the range of mountains, and eventually came to the foot of the cliff which ended in the sea, and the difficulty was how they should take the line on. It was decided to lay a submarine cable round the cliff, which was done, but the rocks very soon cut through the guards, and the cable was interrupted. A second cable was laid, which quickly shared the same fate. In the meantime a path up the mountain from the west side was discovered, and after improving it somewhat the posts and wires were carried to the top, but when they came to the east cliff it was found to be about 2,000ft. deep, down which they had to throw the wire. It used to take a Beluchi, accustomed to hill climbing, five days to go overland from the post at the bottom to the post at the top. This line, also, was very unsatisfactory, as rocks were constantly falling on it, and they next turned attention to another pass called the Buzi Pass in the native language, the Ass's Pass. He sent an assistant there, who got to the top of the mountain, but he told him that although he arrived late at night, and dead tired, he was unable to sleep, because all night long he was thinking how he should get to the bottom again. In other parts of the country there were salt plains which much interfered with the good working of an overland line. The cables on the other hand had their own peculiar difficulties, such as had been mentioned in the Paper. Although these lines were laid in such an unfavourable country there had been no total interruption in the Persian Gulf line since 1885. In Persia they had to go over four mountain passes to get to the plateau, and down another to reach Teheran, the elevations being from 7,700 to 8,800ft. Mr. Walker had told them what kind of country Persia was, but he would read a passage from a report by his former chief, Sir John Bateman-Champain, which would perhaps present the case in even more forcible colours:—"The heat in summer is nearly as distressing as in India, and the inspector on his urgent repairing trip can hope for no shady tree nor for a single stream of water. As a general rule, with few exceptions, his way lies over glaring salt or stony deserts, or under scorching barren rocks. In winter, the cold on the mountain ridges and elevated plains is as trying as, and perhaps more dangerous than, the heat of summer. In severe seasons the passes are occasionally so blocked with snow that no native traveller dreams of pursuing his journey, but the telegraph official is bound to force his way through obstacles which are an effectual bar to ordinary traffic. The wretched caravanserais, or hovels, where shelter can be found lie apart from one another 20 or 30 miles, and in many parts of Persia there are no intermediate villages. The inhabitants are not inclined to be hospitable, and the difficulty of procuring help, supplies, or lodging, is indescribable. The roads and tracks are generally as bad as possible, and wheeled conveyances are unknown. The risk to life in crossing snow drifts is great, and the privations which must be endured when, after struggling in a bitterly cold temperature all day, the nights have to be passed in some wretched hut, or even cave, with barely enough fuel or food to support life, can scarcely be imagined. It was after a week of such work that Mr. Hamilton, a clerk at Dehbeed, formerly a sergeant of the Royal Engineers, died from inflammation of the stomach brought on by cold and exposure." Since 1886, however, the Persian section of the line had only been interrupted once for nine hours. In his opinion they should devote attention more to the Turkish route, which was the easiest to the East, if they could only persuade the Turks to allow it to be put in good order, and have English clerks work it for them.

Lieut.-Col. H. L. WELLS, R.E., M.I.E.E., said he could perhaps give a little more information with regard to Persia. Mr. Walker had referred to the case of one of their officials being murdered, that was in 1872, and he must say in defence of the Persians that in that case it was the man's own fault. Two sergeants were shot, and in one case the Englishman was entirely to blame, and in the other a man died bravely defending his possessions. Being a soldier, he preferred fighting to parleying, though his opponents were six to one, and naturally he had to succumb. The wilful damage in Persia, which at first was very great, was now not worth serious notice. Since he had charge of that section there had been only one case of total interruption from that cause, and this was due to some person, who thinking he owed a grudge to the local governor, cut the wires. In another case, to which Mr. Walker referred, where the local governor from spite against the Government tried to damage the line. He only smashed three or four posts and forgot to cut the wires, which were only rendered unworkable because they were lying jumbled together in the muddy ground. Nowadays, thanks to Cardew's sounders, they could work through long distances even when the line was lying on damp earth and snow. In Sir John Champain's and Sir Robert Murdoch Smith's time the natives were very bigoted, but little by little the Telegraph Department had found its way into their affections. The officials, like all Englishmen, were hospitable, and they liked to speak and chat with their neighbours, and by degrees they became the confidants of the villagers, and even by the governors were much looked up to. When the tobacco régie came to an end, and a great feeling was expressed against all European institutions throughout Persia, the Indo-European telegraph was specially exempted by name. The lines were unprotected for hundreds of miles, but no fanatic interfered with them, or even smashed an insulator. Only last spring a typical case occurred, when a revolution took place owing to bad government in the province of Fars. The people, as usual, flew to the representative of the Indo-European telegraph, and sent messages to the Shah, knowing that in this way their com-

Digitized by Google

plaints would be heard. The officials were sometimes placed in rather a difficult position in this way, having to represent rebels ; but still the truth did get to the Shah by these means, and generally had a beneficial effect. Governors had been spared from unjust punishment, and the population had been freed from tyrannical masters through the operations of the telegraph. The line from Shiraz to Jask would, he was sure, be welcome ; but before it could be undertaken with success, the Government must, as the Hon. George Curzon insists, be more strict than at present, for last year the whole of the Shiraz to Jask country was in revolt ; and the line, if made, would be subject to all sorts of difficulties, until the Persian Government took this district into its hands ; at the same time, making the line might conduce to that end. The Shah took interest in the telegraphs and electricity. He had the electric lights in his theatre for passion plays ; telephones were well known, and a network of telegraph wires ran throughout the country ; but, owing to mismanagement, the want of funds, and the peculation, which was chronic, they seldom worked satisfactorily. The Meshed line, to which Mr. Walker had referred, was now under the charge of the Indo-European Telegraph Department. Before he left the country, the Shah handed over to him 10,000 tomans (a toman being worth about 6s.), to be spent in three annual instalments on the line, in addition to the annual outlay. The Shah had lately started a second line, *via* Shiraz and Mohammera, making the connection with the Turkish lines. He was glad to find that Mr. Walker, as well as Mr. Ffinch, were in favour of land lines. He was quite sure that land lines were better than cables for commercial work ; notably, the speed on them is better, and they were so quickly repaired. The Indo-European system had continually taken up the work of the cables when they broke down. Year after year, until quite lately, as soon as the monsoon came round, a total interruption of the Eastern Telegraph system used to occur (until within the last two years), and when that occurred the land line came to their aid, and carried the whole traffic. In 1882, during the Egyptian campaign, when Arabi's men cut the line connecting Suez with Port Said, the only means of communication between General Wolseley, at Port Said, and Admiral Hewett, at Suez, was *via* Aden, Bombay, and Persia. Each morning they used to clear the line, and those two chiefs had a talk with each other. He was then temporarily in charge at Teheran, and remembered the bread riot which occurred at a small town 200 miles to the south, which looked as if it would be the cause of a total breakdown of communication between the Eastern and Western world. The rioters seized the telegraph clerk and held him to his desk, and insisted on an immediate reply to their petition to the Shah ; others climbed the post, and said if they did not get an answer within ten minutes they would smash the lines ; and it was only by the official's excellent knowledge of the language of the people, and the esteem in which he was held, that he was able at last to persuade them to wait until their petition could be forwarded to the Shah, who was away some distance from Teheran. Some years ago, when all the lines in England were interrupted by heavy snow storms, an inquiry came *via* Bombay and Teheran from Cornwall to know what London was about. Mr. Walker had referred to the ease with which a line could be carried through Afghanistan, but he feared there would be more difficulty than Mr. Walker anticipated, there were so many tribes at variance with each other, and he feared for a long time they would come and damage the line in the hope of the blame attaching to their neighbours this being a favourite trick with that sort of people. He was not so much in favour of a line *viâ* Meshed, Herat and Candahar, as of the Turkish lines being prolonged. The former would be essentially a peace line, for as soon as there was war, enemies to Persia or England could in 28 hours send a dozen horsemen across the frontier and cut up the wires and carry them off. The Cyprus, Aleppo, and Euphrates Valley route connecting with Baghdad, Jask, and Kurachi, through Southern Persia, would be the better route.

The CHAIRMAN (Sir Thomas Sutherland), in proposing a vote of thanks to Mr. Walker for his admirable Paper, said he had brought the history of telegraphic communication with the East up to date, and had made some most valuable suggestions which, no doubt, would be acted upon at no distant date, both with regard to the extension of the system and to the economy which would attend it. In reading his observations on this point, the idea occurred to him that it would be better if his friend Sir John Pender had been asked to preside, because he would be likely to bring more influence to bear on the main object which Mr. Walker advocated than any one else. Probably, if some gentleman came forward hereafter to read a Paper on cheap passage and freight to India, Sir John Pender would be asked to take the chair. Looking at the question of telegraphing from the point of view of a shipowner, he was amazed to find that, whilst it was possible to send a ton of merchandise from London to the uttermost ends of the earth for something like 50s., it cost 20s. to send a message of five words to India. It must have occurred to many who saw the wonderful manner in which the telegraphic system had developed, and the great improvements which had taken place through the opening of the Suez Canal, and the acceleration of steam communication to all parts of the world, how absolutely useless the telegraphic system would be if to-morrow they were relegated to the days of sailing vessels and the Cape of Good Hope route. In 1867 or 1868, when telegraphic communication was first opened with North China, through Russia, he happened to be residing in Shanghai, and should never forget the astonishment of the Chinese people on discovering that they could not only obtain news of the European markets in that way, but also remittances. The system of transacting business by bills had been almost obliterated by the system of telegraphic exchange which now existed. On the occasion of the Russian scare which took place in 1885, the Government and the Navy were, as usual, unprepared, and it was found necessary not only to engage in this country many of the fastest vessels connected with the Atlantic trade for the purpose of arming them as cruisers, but also to telegraph and engage vessels in Sydney, Hong Kong, and the Cape, and it was within his knowledge that the vessels in Sydney and Hong Kong were engaged and armed, and the men were practising their guns at sea, before the guns were placed on board the auxiliary vessels in Liverpool. That showed how dependent we were on the electric telegraph for the security of the empire. With regard to the suggestions made for the extension of numerous lines and additions *via* Persia, Russia, Central Asia, and so on, he thought it would never do for this country not to have an independent line of its own, solely devoted to its own service, for the purposes of peace or war.

Mr. CHARLES BRIGHT wrote as follows:—Though present at the meeting, I had no opportunity of taking part in the discussion. I would point out that Messrs. Bright and Clark were engineers to the Indian Government, in connection with the first Persian Gulf cable, and that this cable was laid in 1863, under the personal superintendence of the late Sir Charles Bright. The late Mr. J. C. Laws was his principal assistant, and he was further assisted by the late Mr. F. Lambert and Mr. F. C. Webb, besides several others. The first Persian Gulf cable of historic interest, in that it was the first cable which was a complete success from the outset, no hitch whatever occurring during the construction or laying of the same. Moreover, this was the first cable which underwent a proper system of testing during manufacture, the testing instruments being also more delicate than those previously used. Every joint was, for the first time, tested by the accumulation test of Mr. Latimer Clark, F.R.S. The copper conductor gave an average conductivity (or purity) of 90 per cent. ; in previous cables this had been as low as 40 per cent., and under. To the design of Messrs. Bright and Clark, the conductor (225lbs. per N.M.) was built up in a segmental form, with an outer surrounding tube, the whole being drawn down to a circular form, thus combining the electrical advantages of a solid wire with the mechanical advantages of a strand. Several practical difficulties were found in the construction of such a conductor, however, and the expense of a special wire of such a form was also very great. Messrs. Siemens Bros. have since adopted a conductor based on the same principles, having a large centre wire surrounded by small wires. It was in connection with the Persian Gulf cable that Messrs. Bright and Clark first made experiments with gutta-percha at different temperatures, which led to the logarithmic curve law for the variation of electrical resistance of such substances by temperature. This core (275 lbs. of G.P. per N.M.) was manufactured at the Gutta-percha Company's works, Wharf-road, and this was armoured at Messrs. W. T. Henley's works, that firm having obtained the contract for the same. In the manufacture of this cable the core was for the first time tested under hydraulic pressure with a view to the exposure of any incipient faults in the insulation due to airholes, and so forth. This plan has since formed a part of the system of Messrs. Siemens Bros.' Cable Works. In practice it is found, however, that besides being exceedingly expensive, the pressure tends sometimes to "mask" factory faults, as well as to divulge them. One speaker referred to the risk of interruption to a submarine cable. Surely it is acknowledged by now that this is infinitesimal, compared with the same risk in the case of an aerial line, running across a desert country, in a tropical climate, with heavy rainfalls.

LEGAL INTELLIGENCE.

McGeagh v. Elmore's Foreign and Colonial Patent Copper Depositing Company (Limited).

An action was brought in the City of London Court, this week, in which the defendant Company was unrepresented by counsel.

The Plaintiff stated that he was induced to take shares in Elmore's French Patent Copper Depositing Company by seeing a statement in the prospectus that a dividend of 10 per cent. would be guaranteed for the first year by the defendant Company, and that there would also be a participation in further profits. The guaranteed amount had not been paid. The Secretary to the French Company was Mr. J. Shurmer, who was also Secretary to the guaranteeing Company ; and the defence set up was that the prospectus in which the statement was made was issued without the authority of the guaranteeing Company.

Mr. SHURMER was examined, and stated that he was secretary to the Guaranteeing Company when the prospectus was issued, and it was quite true that the 10 per cent. had been guaranteed by the defendant Company.

The shares bought by the plaintiff were of an issue upon which the dividend had not matured at the time the 10 per cent. was paid by the guaranteeing Company upon other shares.

Mr. RICHARDS (who appeared for the plaintiff) stated that the case was a test one, and many of the other shareholders were awaiting the result before taking action.

Mr. COMMISSIONER KERR ordered Mr. Shurmer to bring the money claimed into Court ; and the case was then adjourned for a week.

Spencer v. The New Telephone Company (Limited).

In an action tried at Manchester for £14. 15s., for rents for permission to erect poles, &c., the New Telephone Company claimed that the wires were put up with the consent and at the request of the plaintiff's tenants, and the Judge said as the tenants were entitled to fit up the telephone in their premises there could be no trespass on the part of the company in acting at their request. The jury found for the defendants, with costs.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *February* 9, 1894.

Patent Litigation.—Almost the entire interest of the electrical public has been centred for some time on the various phases which patent litigation has been assuming. The state of the patent law has been growing more and more unsatisfactory, and at present it may be said to be little less than chaotic. The Edison lamp patent, for example, after years of constant and enormously expensive litigation, was finally awarded priority by the highest Courts; instead, however, of this resulting in the expected benefit to the patentee, it merely seemed to stimulate infringers, who have since been ceaseless in their efforts to overcome the patent. The celebrated Goebel defence was one of the first means adopted, but although it met with partial success in one Court, it has been overthrown by two others, and a decision from a fourth Court is soon expected. The most startling decision was that of Judge Ricks, who interpreted the blunder of an attorney in endorsing a wrong date on the Edison lamp patent as a dedication of it to the public, so that in this judicial district the patent is now void. The Novak case, in which it was claimed that the Edison combination is broken by the use of a bromine atmosphere in the bulb, has been argued and will soon be decided. Another important case, now on the list of a Federal Court, is in regard to whether the date of application or issue of a foreign patent shall apply in the determination of the life of a domestic patent, but it is not expected that the decision will reverse the law on the point now established. Finally, the United States Supreme Court has just decided against the practice of dividing an invention up among a number of patents by hair-splitting constructions, which may have an important bearing on the telephone and other electrical patents. The result thus far of patent litigation seems to show that our patent laws furnish little protection if an invention is of sufficient value to tempt infringers to continue a legal warfare that may in the end probably result in their favour through some technicality.

The General Electric and Westinghouse Companies.—The condition of the General Electric Company is still precarious, and reductions in *personnel* and contraction in scope still continue. On the other hand, as the fortunes of its great rival wane, those of the Westinghouse Company are on the ascendancy. More than 4,000 hands are now employed in the shops of the latter, and it has just commenced to build immense works covering acres of ground, in which all the valuable Pittsburg ideas in regard to economical processes of manufacture will have their full development.

CORRESPONDENCE.

IS THE HIRE WORTHY OF THE LABOURER?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to the article entitled "Is the Hire Worthy of the Labourer?" this is a subject which not only calls for support, but deserves it. Speaking from experience, I can endorse all that "Superintendent" has brought before the notice of yourself and readers with reference to the work and pay of "electricians in charge" or "superintendents," and it gives rise to a very natural question as to what steps are the most calculated to be attended with success. The organisation of a Union of some sort seems necessary, even though it were restricted to men of at least three or four years' practical experience. It seems to me it would be a great boon if amongst these men a small society could be formed where questions like this could be freely discussed. Your correspondent writes that the "electrician in charge" *may* have to undertake the duties of a driver or stoker in an emergency. I could cite cases from personal knowledge where the electrician had to perform these duties, and where double the number of usual hours have been worked without any increase of pay whatever. Surely there must be many in a similar position, and who could give us the benefit of their experience.—Yours, &c., AN ELECTRICIAN.

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

Our readers are reminded that the 1894 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This valuable book contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.) A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). prospectus on application to the Publisher.

CORRECTION.—A paragraph appeared in our last issue (cut from a local journal), announcing that the debenture holders of the Richmond Electric Lighting Company had applied to the Courts, and had obtained the appointment of Mr. James Worley as receiver and manager. We learn that this announcement was inaccurate, and regret its insertion. We have received the following letter from the Company on the subject:—"SIR: A paragraph (appearing in your issue of February 16th) has been brought to my notice, in which it is stated that the shareholders of the Richmond Electric Lighting Company have passed a resolution for liquidation, and have appointed Mr. Worley liquidator. I beg to deny this statement *in toto*, and would feel obliged if you would inform me on whose authority you have published this misleading, injurious, and wholly untrue statement. I must request that full publicity will be given to this letter.—PERCY W. NORTHEY, Engineer and Secretary, Richmond (Surrey) Electric Light and Power Company (Ltd)."

TENDERS INVITED.—The Corporation of Edinburgh invite tenders for the following work in connection with the electric lighting of the City:—Contract 5, construction of concrete culverts and laying of pipes and casings; Contract 6, supply of cast-iron pipes, casings, and road service boxes; Contract 7, supply of stoneware casings and insulators; Contract 8, supply of copper strip; and Contract 9, supply of armoured and unarmoured insulated cable. All information may be obtained from Prof. A. B. W. Kennedy, 14, Old Queen-street, Westminster, London, S.W.; and tenders must reach Mr. W. Skinner, W.S., Town Clerk, City Chambers, Edinburgh, not later than March 17th. Further particulars appear in our advertisement columns.

——— The Sutton (Surrey) Local Board invite tenders for the purchase of the powers granted to them by the Board of Trade under their electric lighting Order, 1892. The system proposed to be used is the low-tension one. Particulars can be obtained of the surveyor, Mr. A. G. Greatorex. Some further particulars are given in our advertisement columns, where it will be seen that tenders must be sent in to Mr. T. D. Pettiver, clerk, Local Board Offices, Public Hall, Sutton, Surrey, by 12 o'clock of April 4th next.

——— The Corporation of Harrogate invite tenders for plant in connection with their proposed electricity works. The plant consists of refuse sorting and drying apparatus, with accessories; steam boilers and accessories; steam and exhaust pipes; transformers and accessories; distribution mains. Specifications can be had of Mr. Samuel Stead, the Borough Surveyor, Municipal Offices, Harrogate; and tenders must be sent in on or before Wednesday, March 14th. Drawings may be inspected at the offices of Mr. Geo. Wilkinson, the Borough Electrical Engineer, 93, Eastbank-street, Southport.

——— The Swansea Harbour Trustees invite tenders for providing and fixing insulated cables for electric lighting purposes, in lieu of existing wires, on portions of their property. Tenders are to be in by 10 a.m. on the 26th inst.

——— The Borough of Morley invite tenders for the electric-light wiring of the Town Hall now in course of erection. Tenders are to be sent in to Mr. R. Borrough Hopkins, town clerk, by noon on the 26th inst.

——— The Belfast Harbour Commissioners invite tenders for a Cornish boiler for their electric light station at Abercorn Basin. Specifications, &c., can be obtained of the harbour engineer, Mr. G. F. L. Giles; and tenders must be sent in to Mr. W. A. Currie, secretary, Harbour Offices, Belfast, by Monday, 26th inst.

TENDERS ACCEPTED.—The Corporation of Hanley have accepted the tender of Messrs. Spagnoletti and Crookes for the electric light wiring and fittings at the Corporation buildings, the amount of the tender being £3,034. 14s. 1d. The tender is accepted subject to confirmation by the Local Government Board as regards borrowing powers. Some slight modifications are made in the tender, bringing the actual total to £3,000. Other tenders accepted include £207. 10s. for instruments and tools, and £1,000 for meters, switches, cables, fuses, and general stores (no contractors' names given).

Digitized by Google

Tenders Accepted.—The tender of Messrs. W. Nicholson and Son, of Hunslet, Leeds, has been accepted by the Yorkshire House-to-House Electricity Company for the whole of the building work in connection with the extension of their electric lighting station in Aire-street, Leeds.

———— The tender of Mr. J. F. W. Bray has been accepted by the Great Yarmouth Town Council for the erection of an electric lighting station for the sum of £2,620.

———— The Burnley Board of Guardians have accepted the tender of Mr. Fletcher to light certain of the rooms in the building by electricity.

Plant for Sale.—Messrs. Wheatley Kirk, Price and Goulty advertise a large quantity of lighting plant for immediate sale, including several combined sets of ship lighting plant, dynamos, boilers, engines (steam and gas), lamps, accumulators, &c.

Bankruptcy.—Under the failure of Edward Brailsford Bright, formerly practising at Delahay-street, Golden-square, and Adelaide-street, Strand, as a civil engineer, accounts were issued on Wednesday, showing liabilities £8,444, and assets "patents—no present value." The debtor states that in 1884 he became interested with others in the construction of a railway in Greece, and in 1888 he entered into an agreement with a firm of contractors for the construction of the railway. He ascribes his failure to losses in connection with that railway and to costs in an action in respect of an alleged breach of contract.

Liquidations.—A petition has been presented by Mr. John Wilson, of Edinburgh, for the compulsory winding up of Martiny (Limited), and is down for hearing at the Royal Courts of Justice on February 28th.

———— A petition for the winding-up of the Platinum Plating Company (Limited) was on Wednesday adjourned, on a statement that arrangements were being made to satisfy the petitioner's debt.

———— At meetings on Wednesday of the creditors and shareholders of Balfours and Co. (Limited) it was decided to leave the case in the hands of the Official Receiver, to be wound up by that gentleman in his capacity of liquidator.

Messrs. Dorman and Smith.—This firm send us a copy of their new catalogue, which is fully illustrated, and contains descriptions and prices of a large variety of articles actually manufactured by them at their Ordsal Station Electrical Works, Salford, Manchester. The illustrations include a large variety of lamp holders, thumb and key switches, main switches, accumulator regulating switches, switchboards, cut-outs, ceiling plates, balance suspension pendants, shades, reflectors, brackets, cast iron mill fittings, &c. The catalogue is very fully illustrated, and concludes with a description of Rayworth's lineman's detector, for which the firm have executed considerable orders.

Messrs. Drake and Gorham.—This firm have received instructions from the proprietors of *The Morning* newspaper to fit up their new offices in St. Bride-street, London, E.C., with the electric light, the plant for which will include a 14-h.p. high-speed Crossley gas engine, and the dynamo will be of the Electric Construction Company's make. Drake and Gorham's patent spring contact switches will be adopted, and several of the arrangements for this installation will be of special design, including the wrought iron bracket for the arc lamp for exterior lighting. Altogether 140 lights are arranged for, which will probably be increased to 200 later.

Messrs. Peto and Radford.—We are informed that Mr. C. H. Cathcart has disposed of his share in the rights of the firm of Cathcart, Peto, and Radford; that these have been purchased by the remaining partners, Messrs. Peto and Radford, and that the business will be continued by them under the latter title.

Colliery Lighting.—Mr. W. Bakewell, of Attercliffe, Sheffield, has recently supplied to Messrs. John Brown and Company (Limited), of the Atlas Steel and Iron Works, Sheffield, all the cables, lamps, fittings, and instruments for the lighting of their Aldwork Main and Warren House Collieries, the dynamos being supplied by Messrs. Mather and Platt (Limited). The cable is laid for about one mile underground without joints, and the light has proved very satisfactory.

Public Clock Lighting.—Messrs. King, Mendham and Co. have just completed the illumination of the large clock at St. Nicholas Church, Bristol, for which purpose gas has hitherto been used. Three 50-c.p. incandescents are fixed behind the 5ft. opal dial at a distance of 18in. from the back. These lamps are provided with reflectors, so that the whole of the light is thrown on the dial. A portion of the old gas-regulating apparatus has been retained, and by an ingenious arrangement of specially-designed electrical contacts the current is switched on and off the lamp-circuit with a very quick motion, to prevent sparking, and to avoid waste of current during the day. St. Nicholas Church is ultimately to be lighted by electricity, and Messrs. King, Mendham and Co. have the contract in hand.

Electric Organs.—The Hope-Jones Electric Organ Company, Limited, of Birkenhead, are building an organ for the Gilfillan Memorial Church, Dundee. The organ extends across the hall, the whole width of the back gallery, a distance of 40 ft. The instrument is to cost £1,300.

New Firm.—Mr. John Brotherton, late works manager of John Brotherton, Limited, has resigned this appointment, and is commencing business on his own account. He has taken the works occupied some years ago by the Elwell-Parker Company in Commercial-road, Wolverhampton, which he proposes to adapt to the manufacturing of all kinds of wrought-iron and steel tubes and fittings.

National Electric Company.—This Company have opened offices and show-rooms for the supply of fittings and lamps at 2, Holborn-place, High Holborn, London, W.C. Mr. A. C. Cockburn acts as consulting engineer to the Company.

Antwerp Exhibition.—A meeting of the Engineering Trade Section of the London Chamber of Commerce was held at Botolph House, Eastcheap, E.C., on Monday last, at which the subject of the Antwerp International Exhibition, 1894, was brought prominently before the meeting with a view to inducing the members of the Section and the Trade generally to exhibit. It was stated that the Exhibition was a very promising one, as Antwerp was an important seaport visited by merchants and all classes from all parts of the Continent and within easy reach of England; that the duties in Belgium were low; that it was under Royal patronage, and that a joint committee representing the Mansion House and the London Chamber of Commerce was acting in London in the interests of the British Section. It was decided that the Exhibition was worthy the support of the Engineering Trades, and that Sir Edward H. Carbutt, Bart., be requested to confer with the Exhibition authorities as to the appointment of jurors for the Engineering Section.

Water Motors.—We have received a circular from Messrs. P. Pitman and Co., engineers, of Withington, Manchester, setting out their claims for the new "Demon" water motor, which the Company have supplied to many of the leading railway companies and other large users. Several improvements and additions have been made during the past few years, and eight years' continuous use convinces the Company that this will be found a most durable and efficient engine. The motor is direct acting, and, having no dead centre, will start from any position. The wiring surfaces are of the best mild steel, gun metal and brass, and the motor is turned out in good style. The main body of the motor is of rustless iron, by a patent oxide process, fitted with a removable flanged cover. It is constructed to work at any pressure over 30lbs. per square inch, special engines being made for low pressures. Full printed particulars are supplied with each motor, reducing the amount of attention subsequently necessary to a minimum. The motors are made in twelve sizes, from a ⅜in. to a 4in. supply pipe.

Ashford.—The Local Board have appointed a committee for the purpose of considering the advisability of taking the necessary steps to obtain an Electric Lighting Order for the town.

Ashover.—The Directors of the Ashover Hydropathic Company (Limited) have decided to instal the electric light throughout the establishment in connection with other considerable alterations now being made.

Ayr.—The report of the Electric Lighting Committee was presented at the last meeting of the Town Council, wherein reference was made to Mr. Christy's report on the proposed electric lighting of the burgh by water-power. As stated in our last issue, the Council have decided to employ the services of an electrical engineer, who is to report. The Chairman of the Lighting Committee expressed the Committee's appreciation of the services rendered by Mr. Frank Christy, and the value of his report. It was from no want of engineering skill on his part that the Committee had been unable to recommend either of the schemes proposed by him for adoption, but it was entirely owing to the heavy cost. Roughly speaking, it was estimated that it would cost between £16,000 and £18,000 to bring 500 H.P. to the outskirts of the town, and this was the maximum horse-power at their command. It would, perhaps, be worth while expending this large sum if they were sure of requiring the whole of the power at the start; but this was very unlikely, and therefore the initial outlay would be in excess of all probable requirements, whereas, if extensions were required later on, necessitating an excess of power over 500 h.p., then they would be face to face with a considerable difficulty. If they adopted steam they could start with a minimum power, and add as the demand increased. The Burgh Engineer has still to send in his report, which may induce the Councillors to proceed further with the matter, although a disposition was shown at the meeting to shelve the question.

Birmingham.—A proposal has been before the City Council for instructions to be given to the Finance Committee to borrow £1,000 for providing the necessary lamps, fittings, &c., for the electric lighting of the Market Hall. Mr. Parkes, in moving the adoption of the scheme, said that the lighting of the building by gas had been most unsatisfactory for some time past, and they had

Digitized by Google

received a favourable offer from the local electric company, by which the electric light would cost less than the present wasteful system of gas lighting. Thirty-two arcs would be used in the installation, and eight additional were to be put in for external lighting. The proposal was adopted.

BRISTOL.—The report of the Sanitary Committee, who recently visited Walsall in order to become acquainted with the system of electric traction there adopted, has been presented to the Corporation. Alderman Cope-Proctor said there were several matters for and against the system adopted at Walsall, and he thought there was prejudice in the minds of many against the multiplication of poles, lamp-pillars, and wires. On the other hand, he thought it was only just to say that the Walsall system had great claims for quietness, the ease with which the cars travelled, and the speed with which they went up the inclines. With regard to their visit to the Birmingham Central Tramways, he did not consider this nearly so pleasant travelling, and the vibration was disagreeable. Mr. Swaish strongly advised the adoption of a system similar to that at Walsall. The Town Clerk read the conditions under which the Town Council of Walsall allowed the trams to be erected and worked. The whole of the work had to be carried out to the satisfaction of the Council ; the poles to be of a certain height, and to an approved pattern. The Council also stipulated for the use of the poles for electric light purposes. Undoubtedly the Bristol Corporation would adopt similar conditions to those at Walsall if that system were adopted. A question was asked as to whether the Tramway Company was to pay for the concession if it were granted, to which the Town Clerk replied that he was not aware of any such practice in any town. Some further details were discussed, and the Town Clerk was instructed to send the proposed amendments to the Tramways Company, and to report. A strong local committee has been appointed to assist in the promotion of the Tramway Company's scheme for the electric tramways. A preliminary list comprises nearly 150 names of the principal residents.

FRAMLINGTON.—The local authorities have recently received tenders for lighting the village of Framlington, and it appears that the competitors are oil and electric lighting. A meeting of the authorities is to decide which of the rival illuminants is to be selected.

HALIFAX.—The various tenders required in the erection of the electric lighting works in Foundry-street have been received by the Gas Works Committee, and have been accepted.

IPSWICH.—The Town Council recently referred the consideration of the electric lighting project to Mr. John Pratt, who has now presented a report. He suggests that the old Falcon Brewery should be made the site of the central station, that the area of the district lighted should include all the principal streets of the centre of the town, and he estimates that the cost of the necessary plant would be £9,036 ; annual maintenance (including sinking fund), £2,116. 16s.; estimated revenue, £2,350, from the commencement. Eighty townspeople have guaranteed to take the light if the price is not much in excess of gas. The subject will be further discussed at the next meeting of the Town Council.

KEIGHLEY.—At the meeting of the Town Council, on Tuesday last, a motion was discussed to instruct the Town Clerk to give the necessary notice and make application, when the time arrived, to the Board of Trade for a Provisional Order, empowering the Corporation to instal the electric light, to supply light and energy for all purposes, and to schedule the thoroughfares in which the mains are to be laid.

LONDON CITY COMMISSIONERS OF SEWERS.—In reply to a question asked by Mr. Johnson as to what steps had been taken to remove from the streets the obstruction of the gas standards, now that gas had been superseded by the electric light, Mr. Burmester said that it had been decided to remove these at the end of March, as it was the desire of the Commissioners not to disturb the streets during the dark months of the year. The lighting committee agreed that the lamps were now an obstruction. With regard to the appointment of an electric light inspector, the matter had been referred to Mr. W. H. Preece, the City's electrical engineer, and his report is shortly to be presented to the court.

MAIDSTONE.—The Electric Lighting Committee of the Local Board have presented their report upon the offers received for lighting the district by electricity, and recommend that the offer of Messrs. Bourne and Grant be accepted provisionally, and that further negotiations be entered into with that firm with a view of coming to satisfactory terms, and arranging for a transfer Order. In moving the adoption of the Committee's report, Mr. Alderman Ellis said that the Board obtained their Provisional Order with the idea of preventing any one else setting up electric lighting works in the town, and the order must be carried out by July next, unless the Board of Trade were willing to give them an extension of time. The time had, therefore, come when either the Board must move in the matter, or allow some one else to do so. It was now proposed to transfer their Order to a private firm, the Board to have the option of purchasing the undertaking at the end of twenty-one years "without any extravagant items being added to the purchasing price." Messrs. Bourne and Grant proposed to supply additional streets to those scheduled in the Order, and to charge 8d. per unit, less varying discounts. Several members stated they were in favour of the Board undertaking the work themselves, as money could be borrowed at 3 per cent., and they were in a position to do the work. The further consideration of the report was adjourned for a fortnight.

PETERBOROUGH.—The period for lodging objections to the application of the Local Board for a Provisional Order has expired, and the Board will, doubtless, carry through its application, and obtain the Order.

OSSETT.—The Town Council have received a communication from the Local Government Board in reference to the proposal of the Guardians to instal the electric light in the workhouse. The Board point out that they consider that, under the circumstances, the loan referred to should be repaid in 10 years, and not in 30, as suggested by the Guardians. The Council have received numerous communications from electric lighting firms in connection with the installation, and the tenders for the work have also been received. A motion that the tenders be simply opened and referred to the Electric Lighting Committee for report was agreed to.

PENISTONE.—The Brush Company have written to the Local Board stating that, after a careful examination of the map and general conditions of the scheme for lighting the district, the Company has come to the conclusion that it is not practicable to submit a scheme of lighting, by electricity, for a total of less than 600 16-c.p. lamps distributed over 4¼ miles of road, and that any less number would result in a loss.

SHEFFIELD.—The Improvement Committee of the City Council have adopted a resolution that provision be made for the supply of electricity throughout the new Town Hall, and for a modified supply of gas to the staircases and corridors. The architect is to report to the Council whether, in his opinion, it would be desirable to dispense with gas altogether.

STIRLING.—It will be necessary for the Town Council to begin *de novo* their proceedings in opposition to the application of the Caledonian Electric Supply Company for a Provisional Order, as the Board of Trade has sustained an objection to the decision of the Council refusing to consent to the application of the Company, the Board having decided that the statutory thirty days' notice was not given of the Council's intention to apply for a Provisional Order on their own behalf, and that this was necessary when lodging their objections to the Caledonian Company's application.

SURBITON.—The Improvement Commissioners have accepted the offer of Mr. Sharpe to report to them upon the electric lighting of the district at a fee of £26. 5s.

ELECTRO-HARMONIC SOCIETY.—There will be a "ladies' night" this (Friday) evening, at 8 p.m., at St. James' Hall Restaurant, Regent-street, London, W.

SMOKING CONCERTS.—A successful smoking concert, connected with the City of London Electric Lighting Company, was held on Friday last at the London Tavern, under Col. H. C. Seddon's presidency. The company numbered about 150.

———— Under the presidency of Mr. C. J. Phillips, the Telephone Athletic Association gave the second smoking concert of the season at the "Falstaff," Eastcheap, E.C., under the direction of Mr. T. C. Walker. The party, numbering about 200, passed an agreeable evening.

COMPANIES' MEETINGS AND REPORTS.

The City of London Electric Lighting Company (Limited).

The ordinary general meeting of this Company was held yesterday (Thursday) at Winchester House, Sir David L. Salomons, Bart., presiding.

The SECRETARY (Mr. J. Cecil Bull) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN then said : I take it that you will pass a resolution that the Directors' report be taken as read. It will probably be agreeable to you to hear the progress which has been made in this undertaking since December 31st last. Any impartial person reading the report will see that the statement is a very fair one, and that nothing has been exaggerated. The past year was a very bad one from an Electric Lighting Company's point of view, there having been so many bright days and such an absence of fog. At the same time this was favourable to the Company, for the reason that they were busily engaged in erecting machinery during the latter part of the year. It must be remembered that for the greater part of last year our income was made from the current produced by the pioneer stations, and two half units, *i.e.*, a total power sufficient for, say, 34,000 8-c.p. lamps, allowing for no reserve. In order to furnish you with figures upon which to form a fair judgment, I will venture to give the following details :—At the beginning of 1893 there were 20,241 lamps connected to the system, and a total current-supplying capacity equal to 32,000 lamps. At the middle of last year there were 45,919 lamps connected, and the

Digitized by Google

machinery to supply the current was equal to 34,000. At the end of last year there were 65,341 lamps connected, the machinery being capable of supplying 64 000 lamps. At the present moment the number of lamps connected exceeds 76,000, and the machinery to supply them is equivalent in power to 100,000 lamps. In a very short time the supplying power will be greatly increased, the machines now in course of erection being almost ready to give current. There are yet to be connected some 25,000 lamps in districts where the transformer stations are now being equipped, To take a sanguine view, these stations may be ready for service in April, but at any rate within the next four months there is every reason to believe that they will all be supplying current. The experience of the Company has been similar in one respect to that of others. Applications are only made as soon as those requiring current see an early probability of their want being supplied. You must therefore form no conclusion that because nine transformer stations are in use, and supplying 76,000 lamps, the remaining 13 areas in which there are applications to supply 25,000 more lamps is any criterion as to what the demand will be for these areas, but it would be fair to assume the demand will be approximately proportional in most areas to those now supplied, *i.e.*, equal to, say, 180,000. We hope to obtain a night load shortly by the supply of current to Fleet-street and the adjoining districts. Your Board, in order to keep the Company in a good financial position, has decided to start, apart from other depreciation funds, a large fund which should include mains, which is invested in Consols; and the Board considered that it was fair at this stage of operations to take a portion of the premiums which had been received to assist the depreciation funds. In fact, as you will observe, the whole of the premiums received have been devoted to reserve funds. In the course of another year or two, when the machinery is in full work, and every area in the City supplied with current, it appears hardly likely that it will be necessary to touch these reserve funds, except upon special occasions should they arise. I must candidly tell you that, up till to-day, the Board felt considerable anxiety in meeting the demand for current, which had increased at a more rapid pace than it was possible to supply. The difficulty of running machinery in buildings under construction is far greater than anyone who has not had experience in these matters would imagine, and many minor accidents occurred in consequence. Yet I think the severest critic would not judge harshly when it is remembered that since the current was put on day and night some two years ago, the total number of extinctions have been considerably within an hour, even when all the small stoppages are summed up together. In the public lighting also there has been great freedom from breakdown, as can be seen from the City engineer's report, the most serious one having been due to the bursting of a steam valve. In order that the public lighting may be made as secure as human foresight can provide, the lamps on one side of a street are not run off the same machine as those on the other side. Again, the engine which runs the dynamo to supply current for one side is not the same engine as that which runs the dynamo for lighting the other side of the street. The City has only spent 1s. 2d. for gas up to last July in consequence of breakdowns, and has kept the lamp-posts up at an expense of about £1,200 a year. The City now obtains far more light for the increased expenditure than under the old method. The City authorities evidently place complete faith in your Company, because the lamp-posts throughout the main streets are to be removed by the end of March, and would have been sooner removed but for the fact that it was desirable not to disturb the streets during the darkest months of the year.

At the present time your Board feel that the period of anxiety has passed, and that the station will be able to cope with any demand which may be made upon it for current; and, more than this, they believe that the supply will be satisfactory. I know perfectly well that there have been great complaints on the part of many applicants of the delay in obtaining current. Indeed, many who applied for current a year or more ago have not yet received attention. This has not been the fault of the Company. It is quite impossible to carry out the work faster than has been done, and I fully believe that it will not be necessary for me to make any further apologies on this score, because within the next half year the whole of the network throughout the City will be alive. I take the opportunity on all occasions of hearing what our customers think of the supply we give them, and the general consensus of opinion is decidedly favourable. Many gentlemen have stated that their electric light bills are less than their gas accounts were when they used gas. Some express a contrary experience; but, when cross-examined, these latter clients admit that they are getting far more light than they used to have, and exercise no economy to save the current. It is a strange thing that so many people look for vastly more light when using the new illuminant, expecting to pay the same or less money than they did before. A reasonable person can hardly expect such wonders. This would only be true if arc lights were used, but naturally this class of illuminant would not be suitable for City offices, although in many shops such lamps would be found of service. The number of customers are 1,420, and applications come in daily. Apart from the street lighting, which is now completed in the compulsory thoroughfares, we have received the order to light round Smithfield Markets, and we are waiting daily for the order to complete lighting the lesser streets.

A very difficult work is now in course of progress at Bankside, which will shortly be completed. It is that of laying three large cast-iron tubes in the bed of the Thames for the condensing plant which, it is hoped, will be in use by the autumn. If we are fortunate in getting this done, and the winter should prove a dark one, we look forward to very good results. To give you an idea of some of the incidents which have to be coped with in a central lighting station, I may mention that during the intense frost which occurred in January, our boilers no longer received a water supply, in consequence of the water company's mains having burst at Hampton. With great presence of mind, Mr. Jackson, our third engineer, sent to the fire brigade, and, with their assistance, pumped water from the Thames for the boiler supply. The Board feel much indebted to Captain Simond for this service. By the end of the next six months the station will probably be quite complete, but the whole of the machinery which is to be placed within it is not yet on order, but will be ordered as the demand for current arises, always keeping in view the time necessary to produce the machinery. It is intended to erect a number of dwellings adjoining the works, for those employed on the station. You will observe in the report a short paragraph stating that it is the intention of the Board to issue a portion of the Debenture stock. Further issues of stock will only be made from time to time as money is required, in order not to charge the revenue unnecessarily. The Board have under consideration the desirability of publishing regularly returns on the lines as done by the railway companies. It is with much regret that I have to announce that Mr. Charteris has decided to retire from the Board. You are aware that during the last two years he has been suffering from illness, and he feels that a long period may elapse before he will be fit to resume active duty. It is, consequently, against his principles under these circumstances to remain upon the Board any longer. It is also my turn to retire, and I place myself in your hands, whether it is your pleasure to re-elect me or not. The members of the Board are working in the greatest harmony, and they are dealing with your interests to the best of their capabilities. It is therefore considered advisable to leave the Board as it stands at the present time. The resignation of Mr. Charteris does not affect the active Board, since he has been absent from their deliberations for a long time past. The loyalty, intelligence and activity of our staff cannot be overrated. It has been the good fortune of your Directors to have made an excellent selection of their lieutenants, and when you consider that probably at the end of three years from the starting of this Company the whole of the City of London public and private lighting will be completed without a hitch, and so far, I am happy to say, without loss of life due to electricity, it would not be fair to charge the Board or its officers with having been idle, especially as this work will have been done quietly and without any flourish of trumpets. To Mr. Cook, the engineer and manager, Mr. Bull our secretary, Mr. Nisbett, second engineer, Mr. Jackson, third engineer, Messrs. Deakin, Aspinall and Ferguson, and our various other station engineers, as well as Colonel Seddon, engineer of buildings, and Mr. Thomson, the architect, our thanks are greatly due for their unremitting energy. Indeed, I may include the various minor officers and the staff who serve under them, for however great the generals may be they can do nothing without the army. Indeed, generals are often made by the stuff of which their soldiers are composed. The Board, therefore, take this opportunity of bearing testimony to the valuable assistance received from the Staff generally. For myself I need scarcely say that my interest in the progress of the electrical science and industries has been one of the chief objects of my life. In fact, since I have been connected with this Company, I have always regarded the installation with the same affection as if it was my own private one, so that any responsibility that may rest with me as to want of success will not be due to indifference on my part; and if success should crown our efforts, I can only claim my share in common with my colleagues and the officers of the Company, for it will have been attained by the harmonious co-operation of all concerned. I now move—

"*That the report of the Directors and the statement of the accounts to December 31, 1893, with the appropriation of the reserve fund as proposed, be, and the same are hereby, received and adopted.*"

Before putting this motion to the vote, I shall be pleased to reply to such questions as any gentleman present may desire to ask.

Mr. J. BEVAN BRAITHWAITE, jun., in seconding the motion, said that he might perhaps be allowed to allude to the financial aspects of the report. He was very well aware that the form in which the Board of Trade required them to present their accounts was somewhat of a puzzle, but they had endeavoured to throw the gist of the thing into a more comprehensive shape in the revenue account. It would be seen from this that their gross revenue for the year had been £38,556, and that their working expenses, including repairs and renewals, had been £23,091. 13s. 8d., leaving a net revenue of £15,464. 16s. 7d. If they would turn to the end of the report they would find the rest of the information, which, as shareholders, they would naturally ask for with reference to the financial aspect of their affairs. They would there find the key of the position. The working expenses had been 54·2 per cent. of their revenue. When they remembered that in the case of the railway companies, even after being many years in operation, their proportion of working expenses was round about 50 per cent., they must feel satisfied at the working expenses of this Company, now in its infancy, being only 54·2 per cent., in spite of the two causes mentioned which had affected their earnings this year, namely, the unexpectedly fine weather, which had decreased their receipts, and the coal strike, which had increased their expenses. If they could work under such circumstances, with such a comparatively small number of lights on, he thought they might look forward with confidence to the future. The cost per Board of Trade unit delivered last year was 3·181d., as against 4·733d. in the preceding year, showing a reduction of no less than 32 per cent. in the cost of producing the current; and when it was borne in mind that their station was still young, and that the figures before them were the outcome of an average number of only 34,000 or 35,000 lamps, and that they were looking to an ultimate demand for 300,000 or 400,000 lamps, they would see that the Company was making very substantial progress. Another feature which could not fail to be satisfactory was that they had reserve funds now amounting to £40,000 invested in Consols. They were therefore getting into a very strong financial position, and would be able to meet the charges for the maintenance and renewal of their network. With respect to the coming issue of Debenture stock, some persons seemed to be under an impression—he had noticed that that was the case from one or two notes in the technical papers (and he had been surprised at it)—that the proposed issue had taken the Directors quite by surprise, and it was said that as they had issued Preference shares and were now going to issue Debenture stock they were going from bad to worse. If, however, reference was made to the

Digitized by Google

prospectus issued by the Directors when they asked for subscriptions to the Ordinary shares it would be seen that the cost of the undertaking was fully counted before they started. They had really been pursuing a steady and continuous policy from the outset, and, as intimated in the prospectus would be done by them; they first issued their Ordinary shares, then their £400,000 of Preference shares, and now they were about to commence the issue of Debenture stock. After the present proposed issue they would require to issue another £100,000 of Debenture stock. So far as he could see, the original estimates for lighting the City had been very fairly realised, taking the thing all round. He hoped, therefore, that the shareholders would believe that in regard to the issue of Debenture stock the Directors were not taken by surprise in any way, but were carrying out a deliberate policy. The £800.000 already spent had pretty much covered the dead work of the Company. They had got all their tubes in the streets, and a large portion of their cabling in, and the remaining expenditure would be chiefly by way of providing additional machinery for earning revenue straight away. The expenditure of the £100,000 of Debenture stock, so far from putting the Ordinary shareholders further away from a dividend, would do exactly the opposite, for instead of earning £5,000 of net revenue—the interest on the amount at 5 per cent.—it would probably earn much nearer £15,000 or £20,000, because the dead work was done, and the remaining expenditure was only for additional machinery with which to supply additional lamps. He had thought that this explanation was necessary, as some people seemed to have forgotten what was stated in the original prospectus. The fact was that their estimates up to the present time had been remarkably confirmed by their actual experience.

Mr. WILLIAM COOPER said he assumed that there must be a large undeveloped power existing, but he happened to be a shareholder in the Westminster Electric Company. It was very curious that the output of electricity by that company was within a very few hundreds of this Company's, and the net result was within a few hundred pounds of the City Company's, but while the Westminster Company had a capital of £400,000, the capital of the City Company was £800,000, and they were wanting more. He thought that the explanation of the seconder of the motion had thrown some light on the subject, but he would be glad to have any further particulars which could be afforded him with respect to what he had stated. He might add that the Westminster Company had declared a dividend of 5 per cent. on their Ordinary shares.

Mr. WANCKE asked at what price the debentures would be issued, for how long they would run, and when they might be redeemed.

Mr. JOHN NEWTON inquired what advantage it was for the Company to issue Debenture stock instead of issuing further Preference shares.

The CHAIRMAN replied that they had issued all their Preference shares—the whole £400,000.

Mr. BRAITHWAITE: Why, too, should we pay 6 instead of 5 per cent.?

Mr. NEWTON replied that in the building in which they were then assembled some millions of pounds were in jeopardy in consequence of the issue by Directors of Debentures. He could not see why they should not obtain powers to issue more Preference shares, considering the high premium at which those shares stood in the market.

A SHAREHOLDER enquired the cause of the delay in paying the dividend on the Preference shares.

A SHAREHOLDER stated that on the debit side of the capital account, number 9 item was set out as "proportion of management and general expenses chargeable to capital," £24,466. He wished to know whether this matter had been carefully gone into, and whether the Directors were satisfied that none of the amount in question should have been charged to revenue.

A SHAREHOLDER asked whether there was any chance of the telephone tubes being brought into use.

The CHAIRMAN, in reply, stated that the subject of the telephone tubes was still under negotiation, and what the end of it would be he could not say. The matter rested with the City Commissioners; but they hoped shortly to hear something further about it. As soon as a conclusion was arrived at it would be communicated to the shareholders or the Press. With respect to the item of £24,466, to which attention had been drawn, the amount had been apportioned with the very greatest care. A shareholder had asked why the profits could not be paid earlier. He did not know whether that gentleman held railway stocks; probably many of those present did, and they would be aware that a good many of the railway companies had not yet paid their dividends.

Mr. NEWTON pointed out that the Preference dividend was not due until the profits were shown.

The CHAIRMAN, continuing, said that that was so. They had considered it fair to pay the interim dividend on account. In reference to the proposed issue of Debentures, they were not Debentures in the ordinary sense of the word, but debenture stock, and it was decidedly more preferable for the Company to issue Debenture stock—in accordance, too, with the original intention—than to apply for fresh powers to issue further Preference shares. There would be no advantage either, in issuing Preference shares, and by the issue of Debenture stock they would save about 1 per cent. or more in interest, and without endangering in the least the position of the Ordinary shareholders. In fact, their position would be improved. It was no use to compare a company like theirs with a company that had come to grief under circumstances which had no application in the case of a sound undertaking like theirs. The Ordinary shareholders would have the power to take the Debenture stock. He believed the interest it would bear would be about 4¼ per cent.; it would be Five per Cent. Stock issued at 115. The Debenture stock might run to the end of the term, or be redeemed at 125 after a certain period.

Mr. BRAITHWAITE stated that the first option to redeem would be in 1911, when the City Commissioners had the option of buying up the public portion of the Company's undertaking. If they were not then redeemed, and the authorities exercised their option to acquire the undertaking at the end of 42 years, the stock would then be redeemed at 125.

The CHAIRMAN, continuing, said that the stock would be issued in a few days. As to the comparison between their Company and the Westminster Company, the latter had almost got to the end of their work, and the City Company, with double the capital of the Westminster Company, had only just begun theirs. If the City Company could do so well at the beginning of their career as the Westminster Company were doing in their prime, he thought that it showed that the City Company were in a very good position.

Mr. BRAITHWAITE, in answer to another shareholder, stated that the proposed Debenture stock would not give anyone the power to foreclose. It would simply be a first charge on the earnings of the concern, if there were any.

The motion was then unanimously adopted.

The CHAIRMAN afterwards proposed the following resolution:—

"That a dividend of six shillings per share for the half year ended December 31, 1893—making with the interim dividend of 5s. 4d. per share, paid on July 11, 1893, the full dividend of 6 per cent. per annum for the year—be, and the same is hereby declared on Preference shares Nos. 1 to 20,000 inclusive. That a dividend of three shillings per share, being at the rate of 6 per cent. per annum, calculated on the respective instalments for the period ended December 31, 1893, be, and the same is hereby declared on Preference shares Nos. 20,001 to 40,000 inclusive; that the respective dividends be paid on February 23, 1894."

Mr. EDWARD LUCAS seconded the motion, which was carried unanimously.

Mr. FREDERICK W. REYNOLDS then proposed the re-election of Sir David L. Salomons, remarking that after the statement which they had heard from that gentleman, the shareholders had had ample opportunity of judging for themselves of his capabilities. He might state that Sir David Salomons was not connected with any other company, and that his entire services, as far as public companies were concerned, had been at the disposal of the Company from its commencement. When Mr. Braithwaite was fortunate enough to secure the services of Sir David Salomons as Chairman of the Company he thought they might say that their success was assured.

Col. B. H. MARTINDALE, C.B., seconded the motion, which was carried unanimously.

The CHAIRMAN, in acknowledging his re-election, said he would continue to serve them in the future as he had done in the past. When the history of the Company came to be listened to in another year or two he hoped they would find that he had not only done his best, but that he had been successful, with the assistance of his colleagues.

On the motion of Mr. Wancke, seconded by Mr. J. W. Reilly, Messrs. W. H. Parnell and Co. were re-elected auditors for the year ending December 31st next, at a fee of 100 guineas.

Mr. GEORGE HERRING then proposed the following resolution:—

"That the thanks of the shareholders be accorded to the Chairman and Board of Directors and Staff for their able management of the affairs of the Company."

It would, he said, in his opinion, have been almost a miracle if the Directors had been able at present to pay a dividend on the Ordinary shares, but they were working in such a way as would secure a good Dividend in the future. If with the present number of lights the managerial expenses and the Dividend on the Preference shares could be covered, the shareholders might be able to form some opinion of what the position of things would be when they were supplying 400,000 lights, remembering that the additional cost of doing so would be but very small.

Mr. R. PEMBERTON LEACH seconded the motion, which was unanimously adopted.

The CHAIRMAN, in reply, said he thought there was a great deal in what Mr. Herring had said, and that a good dividend would come to the shareholders if people would only take the light, which they had shown themselves ready to do to a greater extent than had been anticipated. If the shareholders would have a little patience the future of the Company was assured. The Directors might, if they had pleased, have strained a point, as was often done, and have paid a dividend on the Ordinary shares, but this would have been a more unsatisfactory proceeding than waiting until they had earned a dividend fairly. The fact that the accounts had been made out so strictly should give the shareholders confidence that no tricks were being played in order to pay a dividend.

The proceedings then terminated.

Oriental Telephone and Electric Company (Limited).

An extraordinary general meeting of the members of this Company was held on Wednesday at the Cannon-street Hotel, Mr. William Addison presiding.

The SECRETARY (Mr. A. B. Chalmers) having read the notice convening the meeting.

The CHAIRMAN said: Without going all over the ground again, I will just remind you that since the present Board have directed the affairs of the Company they have, from time to time, endeavoured to arrive at an understanding by which the two classes of shares, into which the share capital of the Company is divided, should be assimilated, thus abolishing the liability on the partly paid-up shares, and bringing in the Vendors' shares for immediate dividend on reduced capital. The difficulties in the way of the accomplishment of this have until recently been almost insuperable, but after the recent decision of the House of Lords, unfavourable to the contention of the holders of Vendors' shares, your Board was approached by three or four of the largest holders of those shares with a view to endeavour to arrive at a compromise fair and equitable to both classes of shares. As it was clearly desirable that the interests of both sides should be represented at any meeting that might be held between representatives of each class of shares, your Board

Digitized by Google

delegated two of its members, who were holders of upwards of 30,000 Ordinary shares, to meet the representatives of the holders of Vendors' shares. After numerous protracted meetings a provisional agreement was arrived at between the respective representatives on the terms contained in these resolutions. It is true that the Ordinary shares will have to submit to a reduction of 1s. per share; but it must be borne in mind that the vendors also reduce their 20s. shares by 4s. 6d. each. However, I think you will agree that a fully-paid £1 dividend-paying share is a more marketable article and likely to fetch a higher price than, say, two 11s. shares with 18s. liability on them, or than one Vendors' share of £1 fully paid up without any chance of a dividend for years to come. The scheme may not be so advantageous as some of the Ordinary shareholders could have desired, nor is it so beneficial to the Vendors as some of them could wish, but it is an honest endeavour to reconcile conflicting interests and to put all the shares on a level basis, and thus further the steady progress of the Company and the welfare of all its shareholders, who now will have but one interest. As the Company's solicitor is present I will now ask him to address a few words to you in explanation of the scheme. I may, however, add, in conclusion, that proxies received by the Board assenting to our proposal amount to about 205,000 shares.

Mr. JOSEPH ADDISON (the solicitor): I will detain you but a very short time, but as the consideration of the scheme does involve a certain amount of legal question, I will explain it to you at the outset. In the first place you may remember that by the constitution of the Company, it was provided that during the first five years of the Company's existence dividends of 6 per cent. should be paid upon the Ordinary shares, and that the vendors should not participate in the profits until the 6 per cent. had been paid. The agreement contained a further clause that if during any of those five years the 6 per cent. was not paid, then that the deficiency should be made up out of the profits available for dividends in future years in priority to the right of the vendors to participate. That is, shortly stated, the exact effect of the language. What happened was this: During the first five years the dividends did not reach 6 per cent. on the Ordinary shares; there was a deficiency of about £20,000. During those five years no dividends at all were declared on the Vendors' shares. All the profits were distributed as dividends upon the Ordinary shares. After the five years the Board proceeded to carry out the same plan, and distributed all the dividends upon the Ordinary shares; but they were then, as they are now, desirous of effecting an arrangement between the two classes of shares, and for the purpose of seeing what should be done, an actuary was called in, and it occurred to that gentleman that what had been done was not quite right—that what should have been done for the five years was that, instead of appropriating all the profits to the Ordinary shares, the profits should have been distributed upon all the shares, Vendors' and Ordinary, and then that the profits of the Vendors' shares—the dividend on the Vendors' shares—should be taken to make up the deficiency of the previous five years. Upon that view being enunciated the opinion was taken of Mr. Cozens Hardy, who said that the actuary was right. Precisely the same state of facts was laid before Sir Horace Davey, who said, with equal emphasis, that the actuary was wrong. Upon that arising the Directors determined, if possible, to have the question set at rest, and Mr. Ness—a gentleman who has taken part in the proceedings, but who was not a volunteer in disturbing the existing state of affairs—at the instance of the Board, was invited to come forward for the purpose of having this question settled, it being part of the arrangement that the costs incurred in taking the decision of the Court of First Instance should be paid as regards both parties by the Board. The decision was taken, and Mr. Justice Kekewich promptly decided that the actuary's view was right. Mr. Ness then went to the Court of Appeal, which consisted of Lords Justices Lindley, Bowen, and Kay. They decided that the actuary was wrong, and they did so in very emphatic terms. The case was then carried to the House of Lords, and that tribunal, by three of the law lords against two, decided that the view of the actuary was right. The result of that very remarkable litigation is that although the decision is against the holders of the Vendors' shares, there are in favour of the view put forward by them, five judges, consisting of the three judges of the Court of Appeal and two members of the House of Lords, as against four judges, consisting of Mr. Justice Kekewich and three members of the House of Lords. You, therefore, see that four opinions have carried the day as against five, to which may be added, if you think it well, the opinion of Sir Horace Davey, who is now one of the Lords' Justices of Appeal, in favour of the Vendors, as against Mr. Cozens Hardy, who is also a very prominent advocate, in favour of the Ordinary shareholders. The expression of such contradictory views was owing to the documents forming the constitution of the Company, and litigation was no consequence of any improper act or improper attempt to take advantage of the holders of the Vendors' shares. After that question had been set at rest by the decision of the House of Lords, negotiations were again opened with a view to a compromise, and in order that you may quite understand the basis of this compromise, I think I should say one word as to the position of the vendors, and of the Ordinary shareholders in the absence of a compromise. As the matter stands at present, there is an arrear of dividend to be made up to the Ordinary shareholders, to make good which they are entitled to appropriate the dividends, which will be declared on the Vendors' shares for some years' to come. The amount at the present moment is about £11,000. When that arrear is made up, bear in mind, the Vendors' shares will participate for dividend, and they will participate on their 20s. per share as against the 11s., which is the amount paid up on the Ordinary shares. There is also, of course, this further consideration: There is a present liability of 9s. per share attached to the Ordinary shares, and, in the event of the Company being wound up, or being amalgamated, or in any event of that kind, which at present is not foreseen, but which may happen, taking place, there would be a right on the part of the Vendors' shares to receive in full their 9s. per share, which is paid up or credited as paid up, before any distribution could be made out of the assets of the Company to the Ordinary shareholders. Those are the considerations which the Directors had to bear in mind in settling the scheme they put before you. There is, no doubt, one other consideration to which the Chairman has referred, and which will appeal to you as men of business, namely, that in the present state of uncertainty regarding your share capital, the shares of the Company do not stand at an advantage upon the market. The buyer of an Ordinary share does not know how long his present dividend will continue in excess, or how soon the vendor will come to rank with him; and the fact that the Company has one class of shares receiving a dividend, which is more or less uncertain as regards the length of time it will endure, and that there is another class of shares now receiving no dividend at all, in the same Company, does to a certain extent affect the market value. The effect of the scheme is this: You will see that 1s. per share is written off the Ordinary shares, and that 4s. 6d. per share is written off the Vendors' shares. I think that the fair way to look at the matter in the first instance is to treat this 1s. per share written off both classes of the shares, as if it was owing to depreciation in the concession and the wearing out of the patent rights. Therefore, what the vendors say to you is this: "We will write off 3s. 6d. a share on our shares; we will also agree to forego that advantage which we might have in the event of amalgamation or of winding up of receiving our 9s. a share before you get anything; and we will also consent to relieve your shares from liability to call." As I said, the arrears of dividend which have to be made up to you are £11,000. The 3s. 6d. a share, which the vendors write off their shares I think amounts to about £13,125, and therefore you see that on the one hand you are making a concession in allowing them to take a dividend on their shares of about £11,000, which would otherwise come to you, while, on the other hand, the holders of the Vendors' shares are writing £13,000 off their shares, they are relieving you of the liability upon your shares, and they are agreeing because that is what it comes to, that in the event of any winding up or amalgamation, your shares shall rank *pari passu* with theirs in the distribution of assets. Of course, every scheme is more or less of a compromise, and there may be some of you who might have wished to get better terms for your Ordinary shares, while there are holders of Vendors' shares who might have wished to get a certain amount more for their shares. Like all schemes, however, this is more or less a compromise, and the Board believe it to be a fair and honest compromise, and one beneficial to both classes of the shareholders. There is only one further matter I should like to mention, and that is with respect to the course we have to take. We shall have to wind up the old Company, but I hope we may so arrange with regard to the formation of the new Company that that may be carried out at comparatively small cost. I should not have referred to any other topic except that I gather from the secretary that some gentleman has raised the question of costs, which are to be paid so as to free Mr. Ness from liability. I think I have explained the circumstances under which Mr. Ness came forward, and I have explained to you the necessity of litigation. Mr. Ness, as part of this scheme of arrangement, says, You must frank me from the expenses I have been drawn into by acceding to your wish that I should take part in this litigation. The expression used in the scheme is that the costs shall be paid as between solicitor and client. As regards the Company's own solicitor, his costs would naturally be paid as between solicitor and client; but I have been looking through my charges in the matter, and I find it makes a difference of but very few pounds.

The CHAIRMAN proposed the resolution, and the motion was seconded by Mr. Lloyd.

Mr. NORRIS said he understood from the notice of the meeting that it would be necessary for the Company to go into liquidation. The resolution would be confirmed after a fortnight. The Company was going to sell its assets to a new Company, and it would then be in the hands of liquidators. How could it be possible, therefore, that the statement of the Directors in the report was in any way accurate—that "there will be an approaching annual general meeting, when a dividend for the past year will be declared?" No dividend could be paid until the new Company had earned profits for the year 1894. With respect to the scheme, the Ordinary shareholders were asked to give up a preferential claim of £11,000 before the Vendors' shares could possibly receive a dividend, which would not be, judging from recent experience, for six or seven years at least. Beyond that, the Ordinary shareholders were asked to relinquish £11,000 of their capital by knocking off 1s. per share. The Company were further to provide not only the costs of their own solicitor, but also the costs of Mr. Ness. Moreover, the Ordinary shares were a marketable security, quoted and dealt in on the Stock Exchange, and the Vendors' shares were, by the proposal before the meeting, to be put on an equality with the Ordinary shares, whereas they were at present not likely to become a marketable security. He thought the proposal required very serious consideration, and he would move the following amendment:—

"*That the proposal be postponed until after the annual meeting has been held and a dividend paid for the year 1893, and that a committee of three shareholders be appointed to confer with the Directors as to any arrangement with the holders of Vendors' shares.*"

The SOLICITOR, in answer to a question, stated that it would be necessary for the liquidation of the Company to be passed at the meeting by a majority of three-fourths of the shareholders present or by proxy.

Mr. SCRATCHLEY seconded the amendment.

Mr. LORRAINE said that the Chairman had stated that the Directors held 205,000 proxies, which he thought included the vendors. He had been a shareholder in the Company from the beginning, and he had also held Vendors' shares. He had always understood that Mr. Ness in the litigation was an antagonistic shareholder, but they now heard that that was not the case, and Mr. Ness, representing the vendors, had been invited by the Directors to bring the action to which reference had been made. In face of the fact that the Ordinary shareholders had won the case and obtained a decision in their favour from the House of Lords, from

Digitized by Google

whose decision there was no appeal, it was proposed that they should make an arrangement with the holders of the Vendors' shares giving the latter all that they could want supposing that they had won the case.

Commander HANNAY asked what difference it would make to the dividend on the Ordinary shares if the 58,000 shares which were to go to the holders of the Vendors' shares were brought in for sharing in the dividend.

Mr. CHARLES CHESTON said he thought that an unfair attack had been made on the Board. The Vendor shareholders, who had £75,000 in the capital of the Company, had only one gentleman indirectly representing them at the Board, because that gentleman held a large interest in the Ordinary shares as well. It was perfectly certain that if the compromise had not been proposed the Board would have been stopped by the Courts in any further effort to build up another reserve fund in the interests of the Ordinary shareholders. His own view was that the Vendor shareholders were giving up an enormous amount more than they ought to. The Vendor shareholders owed the Ordinary shareholders £11,000, against which, however, must be set the reserve fund. In two or three years the Vendor shareholders, with their fully-paid shares, would be ranking for dividend with the holders of the Ordinary shares, on which only 11s. was paid. The only reserve wanted by the Company was that which was afforded by the liability of 9s. a share on the Ordinary shares. What had been said about the market value of the shares was not, perhaps, germane to the resolution, but everyone knew that a share with a liability of 9s. was not marketable at anything like its true value. There was no question that immediately the incubus of this liability was removed from the Ordinary shares the value of their property would increase. The opposition to the scheme which had been raised by the Ordinary shareholders was certainly a great surprise to him. With reference to the question of dividend that had been raised, it would be an interim dividend.

The SOLICITOR, in answer to Mr. Seaman, said he thought they might assume that the law costs would amount to about £850. Mr. Norris had called attention to a possible technical difficulty, but he believed they would succeed in finding some way out of it with the assent of the Vendor shareholders. The £28,000 odd unissued would not be issued.

The CHAIRMAN in answer to Commander HANNAY, said that the accounts for the past year were not made up yet. For the last few years the dividend had been declared on the whole of the shares. If the scheme were carried out, the dividend would be paid on £171,000 instead of £200,000.

On the amendment being put to the meeting, the Chairman stated that seven had voted for it and about twenty against it. He afterwards put the resolution, and the show of hands was seventeen in favour of it, and seven against it, whereupon the Chairman demanded a poll.

The SOLICITOR, in answer to a question, said that the proxies received by the Directors were alone sufficient to carry the resolution.

The CHAIRMAN stated, in reference to the remarks that had been made about the Directors in connection with their holding of Vendors' shares, that Mr. Grewing held 21,000 Vendors' shares, and had had them for six or seven years. Mr. Ackers had within the last few months bought 491 Vendors' shares, against which he held 25,000 Ordinary shares; and Mr. Lloyd held 959 Vendors' shares, which he had had for five or six years. No member of the Board had recently bought Vendors' shares excepting the few which had been purchased by Mr. Ackers. The Directors held about 23,000 Vendors' shares, whereas there were 75,000 of these shares.

Mr. LLOYD: The Ordinary shares are much more largely represented on the Board than are the Vendors' shares.

The CHAIRMAN: The Directors hold over 40,000 Ordinary shares, I believe.

The scrutineers having been appointed to take the poll, it was at once proceeded with, and

Mr. CHESTON announced that without taking the proxies or using the votes of the Board, the numbers were 44,456 shares in favour of the resolution, compared with 1,162 shares against it.

On the motion of Commander HANNAY a vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN, in returning thanks, stated that they had never had a stormy meeting before, and he hoped that the present would be the last of such meetings.

The proceedings then terminated.

Westminster Electric Supply Corporation (Limited).

The ordinary general meeting of the shareholders of the Westminster Electric Supply Corporation (Limited) was held on Wednesday at the offices, Eccleston-place, Belgravia, under the presidency of the Right Hon. Lord Suffield, K.C.B.

The SECRETARY (Mr. Frank Iago) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN then said: In moving the adoption of the report I must congratulate you on the steady increase shown in the business of the Corporation and on the fact of increased profits and dividend. You will see that the revenue has largely increased, notwithstanding adverse circumstances, first the very strong competition to which the Corporation has been exposed, secondly that the charge per unit has been reduced by one penny for nine months of the year, and also the abnormally light weather and absence of fogs. The accounts show the net earnings to have been £11,346, which, added to the sum of £1,484 brought forward from the year 1892, makes a total of £12,830 net revenue. Out of this an interim dividend has been paid at the rate of 3 per cent. per annum for the half-year ending June 30, 1892, and we now recommend the payment on March 1st next of a dividend at the rate of 5 per cent. per annum for the past half-year, carrying forward a balance of £1,191. As I informed you last year, the aim of the Directors has been to pay dividends out of actual profits, and to put the business of the Corporation on a sound basis rather than to pay large dividends at first. They are, however, pleased to be able to advise the declaration of an increased dividend over the corresponding period of the previous year, after having written liberal amounts off the preliminary expenses and patents and law charges accounts and having made provision for depreciation, sinking fund on buildings and leases and bad debts, which latter are very small in amount. During the past year, in conjunction with the other low tension companies in London, the Board came to terms with the Westinghouse Electric Company for the use of the Hopkinson Patents for the three-wire system of distribution, and have obtained a licence for the remaining term of the patents and any extension thereof. The cost of this licence to the Corporation has been £3,878. 9s. 9d., and as the use of the patents has been the means of saving a much larger expenditure for copper in the mains, the amount has been charged to capital. I may here state that there is no likelihood of our having to incur any further outlay for patents of any kind. No item chargeable to revenue has been carried to capital account and the plant, machinery, mains, &c., have been fully maintained out of the revenue of the year. I am glad to inform you that we were very little affected by the coal strike, as we had provided a large supply on the vacant ground in rear of this building, which was sufficient to carry us on until the contractors were able to recommence delivery. Your attention was drawn, at the last meeting, to the satisfactory decrease in the cost per unit generated, and I am glad to be able to state that a further saving has been effected during the year under review, so that we have been able to make the reduction of 6d. per unit and still show a larger profit revenue. Owing to the rapid increase in the number of lamps installed, doubtless due to the reduction in price of current, and later to the reduction in that of the incandescent lamps owing to the expiry of patents which put an end to the monopoly of manufacture, the Board found it necessary in the autumn of last year to obtain further capital. They therefore asked for subscriptions for £20,000 of the Four and a-Half Mortgage Debentures. The applications from our own shareholders were for £40,300, and the Board thought it advisable, as the money would soon be required, to issue the whole of the balance of £30,000, which completes the debenture issue, and thus give some of the debentures to each applicant. We informed you at our last meeting that we had been requested to supply current to the Foreign Office, and you will be gratified to learn that the installation there has been connected to the mains, and a satisfactory supply provided. The authorities have also decided to do away with the private plant which has heretofore supplied a portion of the current for lighting the Houses of Parliament, and will now take the whole of the required supply from the Corporation's mains. We hope, also, that before long other large Government departments will be added. It is interesting to note that the Corporation is now supplying current to 25 per cent. of the total number of houses in Mayfair, 15 per cent. in Belgravia, and to a very large proportion, which we are unable to estimate, in Westminster. You will see by the report that there has been a very large increase in the number of lamps on circuit. At the date of the report we had the equivalent of 134,268 lamps of 8 c.p. actually connected to the mains, and applications were signed for a further 9,541. At present we have the equivalent of 138,255 lamps of 8 c.p. actually connected to the mains, and applications are in hand for 9,990 more. It is also a matter for congratulation that a large number of our consumers who have had experience of the light for some time have made considerable additions to their installations. As many of you are no doubt aware, our system of supply, the continuous current, gives us an advantage over the alternating current system in that it can be very much more easily used for power, and I am glad to be able to state that there is a considerable increase in the number of consumers who use our current for motive purposes. We hope that, in the future, this branch of our business will greatly increase, and become an additional source of revenue. Among others, the following are purposes for which current is actually being used from our mains:—Working lifts, crane, organ blowing, hair brushing, dentistry, bottle cleaning, wood cutting, engineers' lathes, &c. In conclusion, I beg to move that the report and accounts for the year 1893 be received and adopted.

Mr. JAMES H. POWELL, in seconding the motion, referred to diagrams appended to the wall, showing the applications for current, the generating expenses, and the consumption. He subsequently remarked that he thought the diagrams showed very conclusively how steadily they had progressed.

Mr. WILLIAM COOPER said he regarded the report as extremely satisfactory.

The resolution was then carried unanimously.

The CHAIRMAN afterwards proposed the payment of a dividend at the rate of 5 per cent. per annum for the half-year ended December 31st last.

Mr. J. BROWNE MARTIN, in seconding the motion, said he thought they might congratulate themselves on being shareholders in such a Company. Whatever improvements might take place—and improvements were continually taking place—he did not think that anything would supercede electricity for their purposes. They might improve on it, and probably they would do so; and possibly at some future day, if what their able engineer, Professor Kennedy, stated were realised, they might be able to generate electricity at half the present price. He thought there was no doubt that electricity was only in its infancy as to generation and as to use. When one considered the large amount of electricity that was now employed, and yet what a very small proportion it meant to what could be used in London, he thought there was not the slightest doubt that electricity would be not only the lighting but also the motive power of the future; and when they considered that their Company supplied possibly the cream of London, and

Digitized by Google

that it had its powers for 42 years, he thought they could only congratulate themselves on being shareholders in it.

The resolution was carried unanimously.

Sir DOUGLAS GALTON, K.C.B., F.R.S., then proposed the re-election of Lord Suffield. He had, he said, never known a Board the members of which had attended more constantly and more regularly than had the Board of the Westminster Electric Supply Corporation, and among those who had thus devoted themselves to the service of the Company, none had been more diligent than Lord Suffield.

Mr. DARNTON HUTTON seconded the motion, which was unanimously agreed to.

Mr. S. R. SCOTT afterwards proposed the re-election of the other retiring Director, Mr. W. Hayes Fisher, M.P. In proposing the resolution, he felt, he said, that the shareholders were asking the Directors to perform their duties for a very small remuneration; but he hoped that in the future the shareholders might be able to deal more liberally with the Board.

Mr. PIERCE seconded the resolution, which was unanimously adopted.

On the motion of Mr. STRATTON BOULNOIS, seconded by Mr. COOPER, the retiring auditors, Messrs. Cooper Brothers, were also re-elected.

The CHAIRMAN thanked the shareholders for the confidence which they had placed in him by re-electing him. It was true, as Sir Douglas Galton had said, that he had given the best attention in his power to the affairs of the Company. He had taken the deepest interest in what was one of the most interesting undertakings at present known; and except when he had been ill, or some special reason had prevented him from attending, he had never missed a Board meeting. He could say the same for his co-Director, Mr. Hayes Fisher. As long as they favoured him with their confidence he would do his utmost to promote the welfare of the Company.

Mr. FISHER also returned thanks. He was, he said, the largest shareholder in the Company, or very nearly so; and he therefore had every reason for desiring, on his own behalf as well as that of the shareholders generally, that the dividend they had declared that day might be continuous, not alternating, or, if it alternated, that it might do so in the direction of something higher than 5 per cent.

Lord GALLOWAY then proposed a cordial vote of thanks to the Chair- and Directors.

Mr. F. A. WHITE seconded the motion, which was unanimously agreed to.

The Chairman, in acknowledging the vote, expressed a hope that they would meet in another year with an even more favourable account than he had had the pleasure of giving them that day.

Chelsea Electricity Supply Company (Limited).

The annual ordinary general meeting of this Company was held on Tuesday at their Central Station, Draycott Place, Sloane-square, Mr. J. Irving Courtenay in the chair.

The SECRETARY (Mr. S. J. Cluer) having read the notice calling the meeting, the report of the Directors was taken as read.

The CHAIRMAN said: Gentlemen,—It is a great pleasure to me to be able to congratulate you to-day on the encouraging results of the past year, and to feel justified in saying that there is a reasonable prospect that the Company will continue to improve its position. At our meeting last year I was able to show that the corner had been turned and that we had attained a dividend-paying condition. During the year 1893 progress has been so satisfactory that there is a considerable increase in the profits, the dividend we recommend this year being double that paid last year, on a paid-up capital which is over 10 per cent. larger than that of 1892. I will first draw your attention to the balance on the sale of the South Kensington District, £2,600. 18s. 1d., shown in the Net Revenue Account No. V., and to paragraph 2 of the Report, as I wish it to be clearly understood that our Dividend comes out of the ordinary business of supplying current, and is quite independent of this exceptional item. We have complied with the views of the Board of Trade, and have taken a large sum from Preliminary Expenses and placed it to a Suspense Account. This amount, under ordinary conditions, would legitimately have remained in Capital Account and have been dealt with year by year; the Directors have, however, decided to write £2,500 off this amount in the General Balance Sheet; they have also placed a further sum of £1,000 to Renewals and Depreciation Fund Account. There still remains a balance of £3,105 2s. 7d., out of which the Directors recommend a dividend of 5 per cent. on the share capital, which will absorb £2,485. 18s. 4d., leaving £619. 4s. 3d. to be carried forward. I feel certain that the shareholders will consider the Directors have made a prudent allocation of the profits. The expenditure for the year on capital account, as shown on page 2 of the accounts, is £18,118. 17s. 6d. The actual amount is considerably larger than that, as you will notice that the credit of £5,453. 10s. 4d. opposite the item of preliminary expenses has been deducted from that column. A large portion of this expenditure is due to an extensive increase in the mains, for, besides the ordinary small extensions always necessary, we have covered a large area extending from the Chelsea Embankment on the south to the Fulham-road on the north, and we believe, from the direction which rebuilding is taking, that this area will in the future develop in the same manner, and to a similar extent, as the area previously occupied by our mains has developed. I wish now to allude to the purchase of the works of the Cadogan Company, which we consider we were very fortunate in securing at the time when a substantial increase of our generating power was absolutely necessary. Our station here, Draycott-place, is now quite full of plant, and the buildings in Manor-street, Cheyne-walk, purchased from the Cadogan Company, are being arranged so that boilers and machinery for 1,000 effective horse-power can be fixed there. This means room for plant to supply an additional 75,000 lamps of 8 c.p. fixed, or say 30,000 lamps in use at one time. You will have noted that the total number of lamps on the Company's mains on December 31st was 40,665. We also had the advantage, by acquiring that station, of being able to commence supply from it at once. The number of our customers in the new area in which the mains have been laid is rapidly increasing, and there is also a large increase in the area previously supplied, so much so that the Cheyne-walk Station is now about to be used to assist our Draycott-place Station as well as to supply the new area. The condition of the plant is excellent, and results prove that its efficiency is well maintained. We have benefited considerably by the improvements made in the machinery, and we see no reason why future improvements should not bring us still more economical results. You will have observed the tabulated statement in the Report shewing how the cost has been reduced within the last three years by the amount of 1⅜d. per Board of Trade unit sold, and you will appreciate the effect of this reduction on the sale of 402,848 units last year. The number of units sold would have been still larger had it not been for the unusual absence of fog. I must also call your attention to the fact that the increase in capital expenditure has resulted in a much larger proportion of profits, a result to be expected, as not only are there certain fixed charges which barely increase at all while the revenue increases, but adequate capital enables us to provide and arrange our plant so as to give the best results. It will interest you to note that the capital expenditure and the payments from profits of debenture interest and dividends for the last three years have been as follows:—

——	Capital Expenditure.	Paid out of Profits.
1891	£74,721	£1,206
1892	81,364	3,002
1893	99,633	4,630

From my remarks, you will have inferred that fresh capital has to be raised for the additional machinery and plant necessary to meet the growth of the Company's business; the Directors, with that view, have considered the advisability of exercising the powers already given them by the shareholders, and they intend, at an early date, to make an issue of Preference capital. This the greatly improved position of the Company should enable them to do on favourable terms. No other points seem to call for special comment on my part, but I shall be happy to answer any questions. I now beg to move—

"*That the report of the Directors and the statement of accounts for the year 1893, now before the meeting, be and they are hereby adopted, and that the payment of a dividend on the Ordinary share capital of the Company of 5 per cent. for the year 1893 be and is hereby approved, to be made payable on April 10th.*"

The DEPUTY-CHAIRMAN (Major-Gen. Webber, C.B.), in seconding the motion, said that if there had been seven more foggy days last winter, and assuming that three-fourths of the lights attached to their system had been in use for six hours on each of those days, their net receipts would have enabled them to pay a dividend of 1 per cent. more on the Ordinary shares. He thought that this figure was sufficient to show them the importance of an ordinary winter to them. He thought it probable that a certain amount of their current would be taken for motor purposes during daylight hours in the future.

Mr. JOSHUA KING asked whether the accumulator system was still a success, and further as to the system lately used by the Cadogan Company.

The DEPUTY-CHAIRMAN stated that the best reply was that the Company had just established in Elm Park Gardens a large accumulator and transformer station, which was only just now coming into operation. As regarded the plant taken over from the Cadogan Company, a certain portion of it was useful, but the purchase was made with a knowledge of that fact.

The CHAIRMAN, in further reply to Mr. King, said that the accumulator system was a perfect success, and the system was the same as that which they began with. He then put the motion, which was carried unanimously.

Sir GEORGE PRESCOTT then proposed, and Mr. Joshua King seconded, the re-election of the retiring directors, Mr. Courtenay and Mr. Nugent Daniell; and the resolution was carried unanimously.

On the motion of Mr. J. KING, seconded by Mr. T. CALLENDER, the auditors, Messrs. Cooper Bros. and Co., were also re-elected.

A vote of thanks to the Chairman and Directors for their able administration of the Company's affairs was afterwards passed.

The CHAIRMAN, in reply, stated that the shareholders had always stood by the Directors, and when the Board had asked them from time to time to take debentures and shares they had done so. That was the strongest proof of the shareholders' confidence in the Directors. They had had a "long pull" to bring the Company through but he was glad to say that they had succeeded, and they had got the undertaking into a dividend-paying position.

The proceedings then terminated.

GUERNSEY ELECTRIC RAILWAY COMPANY (LIMITED).—The fifth annual general meeting of this Company has been held at Hougue-à-la-Perre. A dividend of 2½ per cent. per annum on the Ordinary shares was recommended by the Directors, and provoked some criticism as to the advisability of paying a dividend while the balance-sheet showed a total indebtedness of about £5,000. Ultimately the recommendation of the Directors was adopted. The vacancy on the Board, caused by the retirement of Mr. T. P. Hocart, was filled by Mr. W. T. Palmer.

Digitized by Google

Charing Cross and Strand Electricity Supply Corporation (Limited).

The annual ordinary general meeting of the shareholders of this Company was held at the Town Hall, St. Martin's-in-the-Fields, Charing Cross, on Tuesday, Mr. G. H. Brougham Glasier in the chair.

The GENERAL MANAGER and SECRETARY (Mr. E. Wilmot Seale) having read the notice calling the meeting, the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, in moving the adoption of the report of the Directors for the past year and the accounts, there really is very little for me to do. The first point, which, of course, will strike you, is the loss that the Company has sustained by the death of our late Chairman, a gentleman who was particularly well-known to those who reside in this parish, whom I had the pleasure of knowing for many years, and who was one of the most competent men you could meet with. We all very much regret the death of Mr. Spencer Chadwick. The other Directors did me the honour to ask me to fill the office of Chairman, which I have very great pleasure in doing, so long as I can be of service to the Board and the Company. We state in the report that two actions were brought against the Corporation for injunction and damages, both of which resulted in judgments in favour of the Corporation on all points, with costs. That is a matter upon which we may congratulate ourselves, and it must also be a source of gratification to the shareholders. We tell you in the report what we have done as regards keeping up the station in a proper state of efficiency, and how we propose to deal with certain matters of accounts which I think will also commend themselves to you. We then deal with the earnings, and state what we propose to do with the balance remaining for division. We recommend a dividend of 4½ per cent. for the year 1893, less the interim dividend paid last August, and we carry forward a small balance. Those are the salient points in connection with the report, and I do not think there is anything else which calls for any observation from me. The other matters alluded to in the report will come on later, but meantime I have to move—

"*That the Directors' report and accounts be received and adopted, and that a dividend at the rate of 4½ per cent. per annum on the share capital of the Corporation, less the amount of the interim dividend paid in August last, be declared for the year ended December 31, 1893, and that such dividend be payable on and after February 27th inst.*"

Mr. I. P. MENDOZA seconded the motion.

In reply to questions by Major DOBBS and Mr. TOOTH,

The CHAIRMAN stated that the item on the credit side of the balance-sheet of "sundry debtors for current supplied to December 31, 1893, £6,041," represented the amount due to them at that date. It was impossible on December 31st to collect a sum which could only be ascertained when the meters were examined. Of the £6,000 odd in question a very large portion was now received, and this would enable the Directors to pay the dividend. With respect to the question how it was that they could only pay a dividend for the past year of 4½ per cent., when in the previous year they paid 5 per cent., it was mainly because of "the cutting" of the rates started by other companies. The cutting of the rate by another company which had the right to go through the parish supplied by this Company caused them to lower their own rate, so that they might be on an equal footing to secure the custom of the district through which they passed.

The resolution was then unanimously adopted.

On the motion of Mr. TOOTH, the retiring Directors, Mr. Agostino Gatti, Mr. Stefano Gatti, and Mr. Richard Chadwick were re-elected; as were also the auditors, Messrs. O. R. Johnson and Son.

A vote of thanks to the Chairman and Directors was afterwards passed.

The CHAIRMAN, in acknowledging the compliment, said that it had given him great pleasure to find that the accounts were so satisfactory in view of the severe competition they had had to contend against. Having regard to the accounts presented by other similar companies, he thought they would agree with him that their Company had done as well, if not better, than many of the others. They could not help competition, and they must keep themselves well before the public by going with the times. Had they gone through the year receiving the same amount for electricity consumed as they received in the year before, instead of the dividend being that which they had declared, it would run out to over 6½ per cent., and very nearly 7 per cent. That was what competition had done for them, and they could judge for themselves what the position of the Company would be as soon as the competition had ceased. He believed that the competition which they had had to contend against could not go on, and that cutting rates would die out.

The proceedings then terminated.

Dover Electric Lighting Company (Limited).

The statutory meeting of this Company was held at Castle-street, Dover, last week, Sir W. Crundall, Chairman of the Company, presiding.

The CHAIRMAN explained that this was merely the statutory meeting, and, therefore, formal, but he wished to explain the position of matters. As they were aware, the Company had gone to allotment, and a certain number of their shares had been allotted, not so many, perhaps, as the Directors would have wished, but sufficient to enable them to go on with the business. After this meeting the Directors would meet to receive tenders for the erection of the works. One of these tenders would be accepted, and the works would be proceeded with forthwith. They would also commence to lay the mains in the public thoroughfares, and they hoped to be in a position to supply the electric current before the end of September next. As the shareholders were aware, the Company had made a contract with the Dover Corporation to take over their powers, acquired under Act of Parliament; and not only had the Company done this, but they had completed their contract, so far as the financial part of the operation was concerned, by paying the Corporation the cost of obtaining the Provisional Order, in the first place. The Directors particularly desired to obtain the support of a large number of the local public, not only in order that they might have a financial interest in the Company, but that they might become customers of the Company. It was only by this means that success would be assured. He believed there were a large number of customers waiting to be supplied with the electric light, and the Directors felt confident that when they were in a position to supply them they would soon have sufficient applications to utilise all the current at their disposal. In order to interest the local public in the subject, the Company proposed to hold an electrical exhibition in the Town Hall, together with a reception, when they hoped to be able to show the people of Dover what their intentions were of lighting the district by electricity. The shareholders were aware that the Corporation had decided not only to light the Sea Front and the principal streets of Dover, but also to light the Town Hall by electricity, and had given the necessary orders for that purpose. Similar companies in neighbouring towns round the coast were in a fairly prosperous condition, and it was reasonable to suppose that Dover, when it was thoroughly aroused, would take an "interest" in its electric lighting industry; and it was the intention of the Directors to do their utmost to bring the Company to a successful issue, and he asked the shareholders to induce their friends to take a financial interest in the concern. Dover was exceptionally well situated for such business, and they confidently anticipated, with such exceptional facilities, complete success.

Mr. SELLON, the engineer, fully agreed with the remarks of the Chairman as to the favourable position of the Company. The town had more public institutions than most towns of its size, which, together with the Barracks and Castle, were likely to become large and always prove valuable customers to an electric supply company. He was well acquainted with many of the provincial companies, and felt no hesitation in prophesying an early success for the Dover Company.

After a few remarks from shareholders present, the meeting terminated.

Notting Hill Electric Lighting Company (Limited).

The following is the report of the Directors of this Company for the period ended the 31st December last, to be presented at the seventh ordinary meeting to be held at the offices, Bulmer-place, Notting Hill, on Tuesday, the 27th inst., at five o'clock:—

The expenditure on capital account at the date of the last balance sheet amounted to £76,900. 7s. 7d. During the year a further sum of £1,628. 12s. 3d. has been so expended, bringing up the total to £78,528. 19s. 10d. The two principal items of expenditure are £744. 10s. for mains, and £522. 11s. 11d. for "purchase of patents and patent rights." The result of the law suit between Dr. John Hopkinson and the St. James' and Pall Mall Electric Lighting Company having established the validity of the patent for the three-wire system, the property of the Westinghouse Company, we, in conjunction with the other low-tension electric lighting companies operating in London, agreed to purchase a licence for the use of this system throughout our area for the full term of the patent and for any extensions thereof, the proportion paid by this Company amounting to £522. 11s. 11d. This amount has been carried to capital account, under the heading above mentioned, and is only a fraction of the additional amount that would have been expended on construction had the three-wire system not been adopted.

The revenue account shows a profit of £1,481 7s. 1d., as compared with a profit of £112 6s. 1d. in 1892, and a loss of £554 18s. 6d. in 1891. The amount received from the sale of current shows an increase of £998 7s. 7d., whilst the expenditure shows a decrease of £552 14s 8d. This result has been achieved by the abolition of the City offices and strict economy in every detail of the work, for which great credit is due to Mr. George Schultz, the Engineer and Manager. It was only possible to carry these alterations into effect in the middle of the year; it is therefore estimated that a further reduction in management expenses, amounting to £280, will appear in the accounts of 1894. The Directors wish to point out that the prime cost of the generation of the current during the second half of the year is lower than that appearing in any of the accounts of other London Companies for 1893 hitherto published.

On the occasion of the last general meeting, the Directors voluntarily surrendered one-half of the fees due to them up to and inclusive of the 31st December, 1893, amounting to £1,125, and postponed the drawing of the balance until the present report should have been presented and approved by the shareholders. With a view of enabling the Company to start the new year free from all liability, they now surrender £685 of the balance due to them, making £1,810 in all, and accept in full payment for their services since the commencement of the Company's operations a sum of £440. The balance of net profit, after writing off the loss of £347 16s. 4d. brought forward from the previous year's account, amounts to £1,081 16s. 1d., and out of this the Directors recommend the payment of a full dividend on the 6 per cent. Preference shares, requiring a sum of £640 19s. 4d. The Company has now been placed on a dividend-earning basis.

The Directors are able to report that the machinery and plant at the central station, as well as the mains, are in excellent condition, and that the supply of current during the year has given general satisfaction to the consumers. The number of houses supplied has increased from 124 to 173, and the number of lights from 9,438 to 12,153. The mains at present run past and opposite to 980 houses which are not yet taking current. The

Digitized by Google

Company suffered no inconvenience through the coal strikes, as a contract had been made and a sufficient store laid down in view of possible contingencies.

The Company has been in communication with the Vestry of Kensington with a view to an extension of its area in the district relinquished by the House to House Electric Light Company in the north-west portion of the parish, and has expressed its willingness to undertake whatever work may show a reasonable prospect of profit.

The Directors who retire are Messrs. Alex. Howden and J. T. Jervis, and being eligible they offer themselves for re-election. The shareholders, auditors, Messrs. Deloitte, Dever, Griffiths and Co. retire, and do not propose to seek re-election, and Messrs. Fox, Sissons and Co., a member of whose firm was formerly secretary of the Company, offer themselves for the vacant post.

Telegraph Construction and Maintenance Company (Limited).

The following is the report of the Directors to be submitted to the members at the thirtieth ordinary meeting, to be held on Tuesday next, the 27th inst., at one o'clock :—

The Directors have the pleasure to submit their thirtieth annual report to the members. Their first wish at this meeting is to express their deep regret at the death of their late Chairman, Sir George Elliot, Bart., a feeling which they believe will be fully shared by the proprietors, and they desire to lay before them the copy of a resolution which was passed at the Board meeting of January 9th. Sir George Elliot was one of the original proprietors of the wire rope business before it was taken over by the Company in the year 1864, and, therefore, brought to bear, as a first Director, an intimate knowledge of its details. Resolved: "That on the death of their Chairman, Sir George Elliot, which took place on the 23rd ultimo, the Directors desire to record their deep regret at the loss of a valued colleague, and their appreciation of his services as a Director, a position which he held, with the exception of a very short period, for the space of thirty years, during the last four of which he occupied the post of Chairman with much advantage to the Company."

The Directors considering that Admiral Sir George Henry Richards, who had been Managing Director for a period of 20 years, and who had lately resigned that position, was, from his intimate knowledge of the Company's business, the most fitting person in its interest to fill the office of Chairman, unanimously requested him to accept that position, and he was duly elected.

They regret to report that by the death of Captain Halpin, which occurred on January 20, 1894, the Company has lost a valued officer who had been in its service for nearly thirty years, and who, by his just and upright character, had gained the respect and esteem of the Directors. Captain Halpin was known to many proprietors as Commander of the "Great Eastern," and as Marine Superintendent of the Company.

The accounts for the year show a net profit of £99,435. 8s. 11d., after charging the interest on the debentures. To this sum must be added £41,433. 1s. 9d. brought forward from last year, making a total of £140,868. 10s. 8d. From this amount is deducted the interim dividend of 5 per cent., paid July 25, 1893, amounting to £22,410, leaving £118,458. 10s. 8d. to be dealt with. Of this sum the Directors propose to distribute a dividend of £1. 16s. per share, absorbing £67,230, being at the rate of 15 per cent., and making, with the amount already paid, a total dividend for the year of £2. 8s. per share, or 20 per cent., free of income-tax, leaving £51,228. 10s. 8d. to be carried forward to the next account.

During the past year the following works have been carried out:—A cable was laid between Bonny and Cameroons for the African Direct Telegraph Company: a cable, connecting the Azores Islands with Lisbon, has been manufactured and laid for the Europe and Azores Telegraph Company: and a cable has also been manufactured for the Eastern and South African Telegraph Company, and laid from Zanzibar to the Seychelles and Mauritius. Various lengths of cables have, in addition, been manufactured during the year, as well as 2,483 miles of insulated wire for land lines, &c. Repairs have been effected in the German Government's Greetseil-Valentia cable; and the "Calabria" has been chartered for cable operations in the Mediterranean, and was employed in attempting to repair the 1874 Atlantic cable.

The Company's steamships, and their factories at East Greenwich and Wharf-road, are in good and efficient condition.

The retiring Directors are Sir George H. Richards and Mr. Philip Rawson, who, being eligible, offer themselves for re-election. The meeting will have to appoint auditors for the ensuing year. Mr. John Gane (of the firm of Messrs. Gane, Jackson and Jefferys), and Mr. Patrick A. Glegg (of the firm of Messrs. Welton, Jones and Co.), who retire, offer themselves for re-election.

Yorkshire House-to-House Electricity Company (Limited).

The following is the report of the Directors to be presented to the ordinary general meeting of the Company, to be held at the offices of the Company, Whitehall-road, Leeds, on Tuesday, March 6th, at 2.30 p.m. :—

The net profit for the year ended December 31st last amounts to £1,155 6s. 1d., out of which the Directors recommend that £1,000 be appropriated in reduction of the preliminary expenses account, carrying forward the balance of £155 6s. 1d. In view of the short period during which the plant has been in use, and the fact that in respect to a large portion thereof the contractors' guarantees of maintenance had not expired on December 31st, the Directors do not consider it necessary at the present time to make any provision for depreciation. The absence of such necessity renders it possible to write off the above named comparatively large sum from preliminary expenses.

The Company's permanent plant has only been at work since May 1st last, a period comprising all the summer and only half the winter months: the accompanying accounts, therefore, practically show results obtained during the least favourable portion of the year. The effect of the dispute in the coal trade was to add considerably to the cost of production, although the precaution was taken of securing a large stock of coal before the stoppage. Under all the circumstances, the Directors think the accounts now presented may be regarded as satisfactory, and they are glad to report that the supply of electricity has been maintained in such a manner as, in their opinion, to reflect credit upon the makers of the plant, and upon the Works Manager (Mr. Harold Dickinson), and the rest of the Company's staff.

Almost immediately after the starting of the works it was found advisable to order an additional 200-I.H.P. engine and dynamo, which have been in satisfactory operation since the month of November. In order to obtain necessary capital the Directors invited the existing shareholders to take up the balance (2,634 shares) remaining unallotted of the first issue of 10,000 Ordinary shares, and the whole of these shares have been applied for and allotted.

In view of the expected early increase of demand, a further extension of the Company's works has been resolved upon, and tenders have been accepted for additional machinery of a capacity of 800 I.H.P., and for the necessary additions to the buildings, the whole to be completed and ready for next winter's lighting. The capacity of the works will thus be increased from 700 to 1,500 I.H.P. This extension will necessitate a small increase of capital, in addition to the amount now uncalled on part of the Company's shares, and the Directors will consider how this additional capital can be raised most advantageously for the shareholders.

The Directors have announced that on April 1st next, the standard price of electricity will be reduced from 8d. to 7d. per Board of Trade unit, subject to a scale of discounts, &c.

The retiring Directors, Mr. George Henry Crowther and Mr. Arthur Greenhow Lupton, being eligible, offer themselves for re-election. Mr. John Gordon, jun., offers himself for re-election as auditor.

Scarborough Electric Supply Company (Limited).

The following report will be presented by the Directors of this Company at the meeting to be held on Thursday next, at the offices, 102, Westborough, Scarborough, at 11 a.m. :—

The Company's electric supply station is now in full working order, the business is steadily increasing, and prospects are most encouraging. On September 1st last, when the regular supply of electricity was commenced, there were connected to the Company's mains 468 8-c.p. lamps. By December 31st this had increased to 4,114, and on February 13th to 4,489. By the end of March it is anticipated that nearly 6,000 lamps will be connected. The present capacity of the generating plant provides for about 10,000 lamps. Seeing that it would have been inexpedient to commence a profit and loss account with only a small portion of the machinery at work, the Directors have deemed it advisable to place all receipts up to December 31st to the credit of formation and preliminary management account. Mr. G. L. Beeforth, the Hon. C. A. Parsons, and Mr. G. Alderson Smith are the retiring Directors, and offer themselves for re-election, as does the auditor, Mr. C. E. Bradley, C.A.

NEW COMPANIES, STATUTORY RETURNS, &c.

In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.*]

ELECTRIC TIME-DISTRIBUTING AND CLOCK COMPANY (LIMITED).—This Company was registered on February 17th, with a capital of £5,000 in £1 shares, to purchase or otherwise acquire the invention for Great Britain of Edward Dubois, of Hatton-garden, London, E.C., together with all British and foreign patents now or to be granted for his method of "Improvements in Electrical Clocks" (Provisional Specification, No. 6233, of March 23, 1893), with a view thereto to enter into and adopt an agreement dated February 9, 1894, and made between Edward Dubois, of the one part, and William Aubert, junior (for the Company), of the other part, and to carry on the business of watch and clock makers, electrical clock and watch manufacturers, electrical and mechanical engineers, merchants, &c. William Aubert, junior, is the first managing director.

ELECTRO-CHEMICAL COMPANY (LIMITED). — This Company was registered on February 14th, with a capital of £200,000, divided into 26,000 £10 per cent. Preference and 14,000 Ordinary shares of £5 each, to acquire from the Electrolytic Caustic Soda and Chlorine Trust (Limited), the British Patent No. 2296, of 1890, for "Improvements in the electrolytic production of caustic soda, caustic potash and other products from their salts," and certain other patents for inventions relating to electrolytic and electro-chemical operations, and to carry on the business of manufacturers of and dealers in caustic soda, caustic potash, sulphuric and hydrochloric acids, &c. Some further particulars of the Company appear in the "City Notes."

Digitized by Google

FOREIGN CHEMICAL AND ELECTROLYTIC SYNDICATE (LIMITED).—This Company was registered on February 14th, with a capital of £3,000, divided into 200 "A" shares of £10 each and 1,000 "B" shares of £1 each, to enter into and carry into effect an agreement with F. Maxwell Lyte, C. H. M. Lyte, and Prof. George Lange, for the acquisition of certain patented inventions relating to the production of chemicals by electrolysis or other means, and to carry on the business of manufacturing, analytical, scientific and general chemists. The first directors are Cecil H. M. Lyte and Henry K. Baynes.

PERU TELEPHONE COMPANY (LIMITED).—In connection with the return of this Company, which was filed on January 15, 1894, only the seven subscribers' shares have been taken up, out of a nominal capital of £100,000, in £5 shares, and no calls have been made.

PONTYPOOL ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The first annual return of this Company, made up to December 30, 1893, was filed on January 4th. Out of a nominal capital of £10,000, in £5 shares, 398 have been taken up. Upon 429 of these the full amount has been called, and a call of £4 per share has been made on the remainder, resulting in the payment of £4,021 (which includes a payment of £20 received on shares applied for but not allotted), leaving £20 unpaid.

QUEEN ANNE'S MANSIONS LIGHTING AND HEATING COMPANY (LIMITED).—The annual return of this Company, made up to December 27, 1893, has been filed, and shows that the whole nominal capital of £60,000, divided into 3,000 Ordinary and 3,000 Preference shares of £10 each, has been issued as fully paid.

RAILWAY AUTOMATIC ELECTRIC LIGHT SYNDICATE (LIMITED).—The annual return of this Company, made up to November 6, 1893, has been filed. The nominal capital is £25,000, divided into 400 Ordinary and 600 Preference Shares of £25 each; 396 Ordinary and 520 Preference shares have been taken up, and 200 Ordinary have been issued as fully paid: Upon the remaining 196 Ordinary shares the full amount has been called, upon 480 Preference shares £15 per share, upon 30 Preference a call of £10 per share, and upon 6 Preference £5 per share has been called, resulting in the payment of £11,550, leaving £985 in arrears; £45 has been paid on four forfeited shares.

SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to January 3rd, has been filed. Out of a nominal capital of £1,000,000, in £5 shares, 98,699 shares have been taken up, and 19,750 of these have been issued as fully paid. Upon the remaining 78,949 shares a call of £3. 10s. per share has been called, resulting in the payment of £279,851. 10s. The sum of £3,530 has been paid on 1,201 forfeited shares.

S. Z. DE FERRANTI (LIMITED).—The annual return of this Company, made up to January 13th, has been filed. The whole nominal capital of £100,000, divided into 2,000 Preference and 8,000 Ordinary shares of £10 each, has been taken up, and, with the exception of seven Preference shares, issued as fully paid. The sum of £70 has been received in respect of the said seven shares.

CITY NOTES, &c.

BLANDY'S PATENTS SYNDICATE (LIMITED).—At the ordinary general meeting on Tuesday, the Chairman stated that the Directors had been trying to establish a company, with a capital of £40,000, to take over the patents and work them, and he believed they would succeed: but meanwhile it was necessary that the shareholders should subscribe £1,000 (for which they would receive debentures), which would come to 1s. 4d. per share. A resolution was passed approving of the proposal, and the Directors' report was adopted.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend at the rate of 6 per annum on the Preference shares, and at the rate of 5 per cent. (the maximum which, according to the Articles of Association, can be paid on an interim dividend) on the Ordinary shares of the Company, for the six months ended December 31st last, and payable 1st prox.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended February 18th, were £938, the same amount as in the corresponding period of 1893. The total receipts for the half-year amount to £6,665, as against £6,800 for the corresponding period of last year, being a decrease of £135.

ELECTRO-CHEMICAL COMPANY (LIMITED).—The prospectus is issued of this Company, which is registered with a capital of £200,000, in 26,000 Preference shares and 14,000 Ordinary shares of £5 each. Preference shares are entitled to a preferential dividend up to 10 per cent. per annum, and to a ratable participation in further profits after the Ordinary have received 10 per cent. The Ordinary shares are issued as fully paid, in part payment for the British, Foreign, and Colonial patent rights sold to the Company; and subscriptions are now invited for 26,000 Ten per Cent. Preference shares, payable 10s. on application, £1. 10s. on allotment, and £1 per share one month after allotment, the remainder as required. The Company is formed to work in the North of England an electrolytic process for the decomposition of salt, and the production therefrom of caustic soda and bleaching powder. The process has been carried on for two years past at Snodland, Kent, where (the prospectus states) the commercial value has been thoroughly tested on a practical working scale, with results which are testified to by the reports, accompanying the prospectus, from Dr. John Hopkinson, F.R.S., Mr. James Swinburne, Mr. J. Leith, Mr. Walter Tate (of Messrs. A. Norman Tate and Co.), and Mr. George Pilkington, the two last named having analysed the Company's products with satisfactory results. In addition to erecting works for manufacturing, it is proposed to grant licences to paper and soap makers, bleachers, and other large users of chemicals, from which considerable additional revenue is anticipated. The Company acquires the British patents, and all other patent rights applied for in France, Austria, Belgium, Italy, Norway, United States, and Canada, which are taken over from the Electrolytic Caustic Soda and Chlorine Trust (Limited) (the vendor Company), all British patents and foreign and Colonial patent rights, subject to certain reservations, which, however, if carried out by the various firms on whose behalf they are made will bring to the Company a considerable annual income. These reservations are in favour of several of the principal paper makers in this country, who have the optional right to manufacture caustic soda and bleach at a royalty of 15s. per ton, for their own use, at their own works, to the aggregate extent of over 28,000 tons per annum. The amount paid to the Vendor Company for these various rights is £100,000—£70,000 in fully paid Ordinary shares, and the remainder in cash or Preference shares, at the option of the directors. Mr. J. Fletcher Moulton, Q.C., has given a favourable opinion as to the value of the Company's patent rights. The directors include the principal members of several of our leading papermaking firms, and Mr. Leopold Field, of Messrs. J. C. and J. Field (Limited), soap and candle makers, of Lambeth: Mr. James Swinburne is consulting electrician; the secretary *pro tem.* is Mr. T. Hitchcock; and the offices are situate at 57, Old Broad-street, London, E.C. Accompanying the prospectus is the following circular:—"Messrs. Sheppards, Pellys, Scott and Co., 57, Old Broad-street, London, E.C., beg to recommend a careful perusal of the accompanying prospectus and reports, which place before you one of the most promising investments offered for some considerable time, and one that should prove eventually almost as remunerative as a somewhat similar undertaking, 'Brunner, Mond and Co. (Limited),' to which Messrs. Sheppards, Pellys, Scott and Co. have been brokers for several years past."

ELMORE'S AUSTRO-HUNGARIAN PATENT COPPER DEPOSITING COMPANY (LIMITED).—A circular issued to the shareholders of this Company announces that the £5,000 Ten per Cent. Debenture Stock recently issued has been allotted; that the owner of the property taken over by the company has been satisfactorily arranged with; and that the future of the Company is now entirely in the hands of the shareholders. The circular claims that all the promises of the Directors have been fulfilled, and that the Company is on the high road to success, which has been brought about not so much by the help of the shareholders as a body, but by a few who have come forward and have supported the Directors in their policy. In return the Directors state that unless the general body of shareholders come forward with their assistance those shareholders who do assist will have those material advantages offered to them to which the Directors consider they are justly entitled. These material advantages are not more fully referred to. It is now necessary to raise another instalment of money for the purchase of copper and for the putting down of longer tanks for the orders offered, and further, for the erection of a drawbench to allow of the rapid manufacture of special size tubes. The Directors therefore require a further £5,000, which they propose to obtain by the issue of debentures at 8 per cent. instead of 10 per cent. as previously. Unless this invitation to subscribe further capital is universally responded to (applications closed on the 19th inst.), the Directors notify that an extraordinary general meeting will be called for the purpose of creating £30,000 in Preference shares, which will practically take all the profits of the Company. These Preference shares will be offered *pro rata* to the shareholders, and unless each shareholder takes his proportion he will practically lose his entire interest in the Company. The Directors announce that they would have made the issue of Preference shares some time ago were it not that they felt a hardship would have been inflicted upon shareholders so long as there was the slightest chance of failure in the Company's operations, but that now the Company has passed the critical point of its existence the Directors feel no hesitation in making the issue, and shareholders must not complain if they suffer in consequence of their tardy response to these appeals. In conclusion, the Directors claim that this Company (the Austro-Hungarian) "is manufacturing on a commercial scale articles that, so far as they are aware, none of the other Elmore Companies are manufacturing"; "there is now no difficulty in getting abundance of orders"; and finally, "the cash in hand and amounts due are more than the current liabilities and liabilities shortly maturing."

LONDON, DEPTFORD, AND GREENWICH TRAMWAYS.—At the meeting of the shareholders of this Company, on Monday last, Mr. W. J. Carruthers Wain, the Chairman, stated that during the past year several offers had been made to experiment with motors of various kinds on their line; but owing to the fact that the Deptford Company were not prepared to spend money on these experiments very little had come of these offers. The Company had adopted several suggestions for improving their cars, amongst which was that of introducing the electric light. Hitherto the chief difficulty had been the expense, but he understood they were within measurable distance of having electric light supplied to them, which would be effective, steady, and cheap, and they would then only be too glad to place it into their cars. The electric light would certainly form an attraction, and increase their traffic.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED). Notice is given that the transfer books of this Company will be closed from the 19th to the 27th inst. inclusive, preparatory to the payment of dividend.

WEST AFRICAN TELEGRAPH COMPANY (LIMITED).—The half-yearly interest on this Company's Five per Cent. Mortgage Debentures, due on the 1st prox., will be paid on and after that date by the National Bank of Scotland, 37, Nicholas-lane, E.C. Coupons must be left three days for examination.

Digitized by Google

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the two weeks ended February 15th were £2,615, as compared with £3,009 for the corresponding period of last year. The October receipts, estimated at £3,822, realised £3,867.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The Company's traffic receipts for the week ending February 16th after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,287.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 824.—Vol. XXXII. FRIDAY, MARCH 2, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

Pending the issue of the final Board of Trade Regulations for Electric Traction, those of our readers who are interested in the matter will be able by study of our report of the conference, which we print elsewhere this week, to obtain a good idea of the amendments which are being introduced. In many parts we have been obliged to condense the remarks, especially where these were of a conversational character. As Regulation No. 14 drew near, discussion waxed warmer; over No. 13 there was a long wrangle, beginning with and ending in nothing in particular. When No. 14 was at last reached there was an ominous hush, and every eye was turned on the chairman, from whom a weighty speech was expected. Weighty perhaps it was, but brief. "Now we come to Regulation 14, amended by these words, please, after the word 'shall' insert 'take all reasonable precautions to.' Now, what has anybody got to say about that?" There was no need to invite speeches, for many a solemn harangue had probably been prepared, but the voluntary amendment had knocked the bottoms out on both sides. The Institution of Electrical Engineers proposed their amendment notwithstanding, and in the discussion which ensued it appeared that most of the members could not divest their minds of the fact that there was nothing to fight about. Sir Courtenay Boyle put an end to it at last by assuring them that the regulation, as amended, had very little effect one way or the other. It is not surprising that this regulation should have created some excitement when we learn that the Permanent Secretary of the Board of Trade himself thought, when this rule was first brought to him, that it threw back the whole responsibility on the traction men, and was practically doing what the rules themselves ought to do. But it was pointed out to him, as we pointed out to our readers two months ago, that it applies only to feeders.

One or two definitions in the new Board of Trade regulations possess some interest. These relate to the measurement or description of differences of potential and to small resistances, and are of a thoroughly practical character. It is proposed to measure a difference of potential of about four volts by the opposing force of three Leclanché cells. This idea was not appreciated by the Committee of the Institution of Electrical Engineers, but their objection was not accepted. The professors probably thought that a nice brass, glass, and mahogany affair would be much better, and possibly the manufacturers thought (unconsciously, of course) that a demand for a new instrument would be a good thing. The very reason for this definition was that a new or special instrument would be needed if the volts were to be measured professiorially, while, on the other hand, Leclanché cells are to be found in every town in the country. In another instance it was proposed to define a connection between two conductors as one which would not appreciably heat when a current of 100 amperes was passed. Neither the resistance nor the leakage of the line was defined in ohms, the former was defined by fall of volts, and the latter by leakage current in amperes.

The subject chosen by Prof. S. P. Thompson for his Friday evening discourse at the Royal Institution was a large one, and the material with which it was illustrated was correspondingly elaborate; the only fault was that an attempt should have been made to compress so much into one hour, but Royal Institution audiences, tolerably familiar with this fault, are ready to forgive it. "Transformations of Electric Currents" of all kinds were raced through, polyphase non-synchronising and other fancy forms of motors, combined with different types of dynamos were shown, either actually running, or by photographs. M. Pollak had brought his rectifier from Paris, and was present to demonstrate its use. In the library, the English version of the combination of motor and commutator was shown, the rectifier of Messrs. Ferranti and Co. Those who imagined that this latter device was to be sold at 15s. 6d. and packed inside the hood of each lamp, had reason to modify their opinion, for the apparatus shown was to turn 10 amperes at 1,000 volts alternating into 10 amperes at 1,000 volts continuous. Most of the experiments were on a large scale, but perhaps the most interesting of all was one of the last, and simplest. A compound horse-shoe magnet was spun on a whirling tube, the poles standing upwards. A strip of copper, about 2ft. 6in. long, 2½in. wide, and $\frac{1}{16}$in. thick, had two slots running nearly all its length, and ending in enlarged holes, not unlike the gamekeepers' wooden affair for carrying dead birds. Thus there were three copper bars connected in parallel. This slotted strip was held horizontally, one end being immediately over the spinning magnet. On the other end was a delicately-pivoted copper ring with an iron core. This was caused by three-phase currents generated in the copper, to spin round. The copper strip formed, at one end, the armature of a three-phase alternator, its length was the triple line, and the far end was the field-winding of the motor; the copper ring was the armature.

Digitized by Google

This interesting experiment was shown to be a development of the Arago disc and rotating magnet, and led the Professor into a speculation about the course which electrical science might have taken, had Arago's researches been properly understood, investigated, and developed. The effect was attributed to "rotary magnetism." The mere creation of such an expression is sufficient, or, at all events, was, a hundred years ago, sufficient to actually impede further investigation. Had a copper disc been used to explore the space round the spinning magnet places would have been found where rotation would take place, and others where it would not. It might have been discovered that a sheet of copper held in a certain position between the disc and the magnet would set up rotation where no rotation would otherwise have been found. By further research, the experiment which we have attempted to describe might have been arrived at, and from this the steps to a multi-phase alternator and motor are conceivable. We might then have had these machines in their present form, the latest developments of modern electrical engineering, even if Volta, Galvani and their batteries had never existed. The whole of electrical science might thus have been diverted and might have arrived at its present position by another route. It is doubtful, said Prof. Thompson, whether in that case we should be speaking of currents passing along wires, or think of anything being transferred along the copper.

It would appear that the Institution of Electrical Engineers is very well off for Papers this session. The last two Papers were well calculated to give rise to interesting discussions, but in each case the subject was hurried through in one night. Gen. Webber's Paper needed study, and would have elicited a good deal of useful comment, while Mr. Kapp's communication could be dealt with off hand by those who have been engaged in similar work. Several members were quite ready to speak, and we believe that more than one iron maker was present. To cut short the discussion in this fashion is to throw away much valuable information, for a similar opportunity may not arise again for a long time. Much of the discussion, as it was, was quite beside the mark, yet the ten minutes' rule was not enforced, whilst on the other hand one speaker who began to allude to the important question of testing armature iron was called to order. The ten minutes' rule may well be relaxed when the discussion tends to drag, but on this occasion closure had evidently been arranged, and under such circumstances prolix and irrelevant remarks should be cut short.

The arrangement for cooling condenser water, whether for jet or surface condensers, which was described by Mr. Druitt Halpin at the Society of Arts meeting recently, and which is illustrated in our columns this week, is compact in form, but not new in principle. At any rate, the evaporative cooler which Mr. Halpin described has been manufactured by several English engineering firms for many years, in one form or another. Messrs. Körting Bros. make, we believe, a stack composed of slanting battens, set so that when the hot water is sprayed from a nozzle on to them it trickles down from top to bottom of the stack, over the series of wooden battens, and reaches the well or tank in a comparatively cool state. A somewhat different form of evaporative cooler is made by Messrs. Ledward and Co. The advantage of this kind of cooler over the tank or cooling pond lies in its compactness. The stack may be placed on the roof, and need not occupy any otherwise useful space. The use of an air blast gives a much greater rapidity of action than is the case with a stack or tower cooling by natural circulation. In some English forms of evaporative coolers an average of about $\frac{3}{4}$lb. of water is evaporated for every 1lb. of steam condensed, a slight increase over the figure mentioned by Mr. Halpin. In residential districts this evaporation would not be as unpleasant as steam condensed from a works chimney, for it would be free from admixture with soot.

We are afraid that our American friends are becoming conservative. The very phrase "municipal rapid transit" that they are so fond of using would appear to connote what we, with our "inborn conservatism," should call reckless driving. At Brooklyn, however, there has actually been a hubbub over the maiming of a few foolish members of the public who have succeeded in getting run down by the electric cars, and, in spite of the characteristically transatlantic opinion of President Norton, of the Atlantic Avenue System, who thinks every person "who gets run over by a trolley car ought to be arrested," there seems a likelihood of something very different taking place. Good roads, high-speed telegraphy, and safe expresses will no doubt follow in good time.

For want of a ready-made intelligible name, a colonial professor, writing on quartz fibres some time ago, alluded to "*Nachwirkung*" to denote the slow return to zero of a twisted fibre. We complained at the time of this poverty of expression, and suggested two extremes, the simple word "creep," and a couple of compound Greek words. There is some objection to the use of a colloquial word in its everyday form for a special technical purpose; but much can be done by the use of suffixes, especially when these are treated in the systematic manner devised by Mr. O. Heaviside. The only fault of his system is that we are hardly ready for some of the terms, though there are always men to be found who will take up such an idea and run it to death, as was recently proved in *Nature*. Prof. V. Boys at the last meeting of the Physical Society used the word "creepage" for the property to which we have alluded. The word seems to be excellently adapted for the purpose. The word "conductance" will be found in the new regulations of the Board of Trade. It is used with reference to the joints between conductors and pipes, and is intended to simplify the monthly records. If the resistance had to be given it might, it was argued, have to be expressed in a long clumsy decimal of an ohm, while for conductance it is only necessary to record "good." This argument is not, however, altogether logical, for the resistance might have been given in microhms.

British Association.—The next meeting of the British Association will be held at Oxford, and will commence on August 8th.

The Late Prof. Hertz.—The late Prof. Heinrich Hertz has left behind him a somewhat extensive treatise on "The Principles of Mechanics treated on a new System," which will be published at Easter, in Leipzig, by Johann Ambrosius Barth.

Digitized by Google

Destruction of a Laboratory by Fire.—The fine engineering laboratory belonging to the Purdue University, Lafayette, Indiana, and which has cost some £35,000 to build and equip, has been completely destroyed by fire. The building was only completed on January 19th last, and was burnt four days afterwards.

Cable Interruptions :

	Date of Interruption.
Cayenne-Paramaribo	Oct. 15th, 1893.
Bissao-Bolama	Nov. 24th ,,
Garachico-Santa Cruz de Palma	Dec. 27th ,,
St. Thome-Loanda	Feb. 5th. 1894.
Malta-Pozzala	Feb. 21st ,,

The Budapest Tramways.—These tramways carried in 1893 12½ million passengers, as against nearly 11 million in 1892, and 8½ million in 1891, the receipts having risen from 700,000 to 1,000,000 gulden (about £100,000). The lines are being extended, the number of cars is now over 100, and a dividend of 8 per cent. on the share capital of 4,000,000 gulden (about £400,000) is recommended.

The Gresham University Commission.—The report of the Commissioners appointed to consider the draft charter for the proposed Gresham University in London has been issued, together with dissentient and other notes, as a Parliamentary paper. The *Athenæum* says that a Committee of the Convocation of London University will be appointed immediately to consider the scheme of the Commission.

The Board of Trade Electrical Standards Committee.—A meeting of the Electrical Standards Committee was held at the Board of Trade on Friday, at which the following members were present :—Sir Courtenay Boyle (in the chair), Mr. F. J. Hopwood, Major Cardew, Lord Kelvin, Mr. W. H. Preece, Lord Rayleigh, Prof. G. Carey Foster, Mr. R. T. Glazebrook, Dr. John Hopkinson, Prof. W. E. Ayrton, and Sir T. W. P. Blomefield, secretary.

The Hermite Process at Worthing.—M. Hermite's system of "electrical sanitation" is now being tried at Worthing. The Town Council has voted a sum of not exceeding £200 to enable M. Hermite to demonstrate the practical value of his scheme, and the British Institute of Preventative Medicine has deputed Sir Henry Roscoe and Dr. Ruffer, its president and secretary, to watch the proceedings on its behalf, and to make the needful chemical and bacteriological analysis.

Aberdeen.—The inauguration of the electric light at Aberdeen took place last Tuesday evening, in the presence of the civic officials and a great concourse of people. Owing to some unforeseen cause, it appears it was impossible to turn on the private consumers' lights; but the street arc lighting seems to have been a great success. The series system is used for this latter, ten arc lamps having already been wired. The private consumers' circuit is arranged on the three-wire system, with bare copper strip conductors.

The Bell Telephone Patent in America.—In anticipation of the expiration of the Bell Telephone Patent on January 30th many electrical supply dealers and manufacturers, says our New York correspondent, under date February 17th, had made preparations to enter extensively into the manufacture and sale of telephones. The American Bell Company, however, interfered with their plans by offering Bell receivers for $1.25 each, at which price anyone can now purchase a standard Bell receiver in a rubber case—the same style as used by the Bell Company.

Telegraph Construction in South Africa.—A Reuter telegram, dated Cape Town, February 26th, states that intelligence has been received that the Portuguese officials, acting on instructions from Lisbon, threaten to oppose the construction of telegraph lines between the British spheres of influence and Tete on the Zambesi. This is the route which it was intended should be followed by the sections of Mr. Rhodes's projected overland telegraph line, to connect Matabeleland to the south of Portuguese Zambesia with Nyasaland to the north.

Electrical Infection.—Apparently very vague ideas exist in some minds of the powers and limitations of the telephone. At a recent meeting of the North Bierley Joint Hospital Board, a proposal was made that the infectious diseases building at the hospital should be connected with the administrative department by telephone. But one member of the Board shook his head dubiously over the proposal. He was afraid, he said, that the telephone would transmit smallpox as well as speech along its wires.

The Royal Society.—The following Papers, among others, were down for reading at the meeting of the Royal Society, which was held yesterday afternoon, March 1st, at 4:30 :— "On the Effect of Magnetisation upon the Dimensions of Wires and Rings of Annealed Iron," by S. Bidwell, F.R.S. ; "On the Relations of the Secular Variation of the Magnetic Declination and Inclination at London, Cape of Good Hope, St. Helena, and Ascension Island, as exhibited on the Magnetarium," by H. Wilde, F.R.S. ; and "On a Spherical Vortex," by Prof. M. J. M. Hill.

Personal.—The many old friends of Mr. A. E. Kennelly on this side of the Atlantic will be glad to hear of his continued success on the other side of the ocean, and to learn that he is about to sever his six-year connection with the Edison Laboratory and join hands with Prof. Edwin J. Houston, whose name is linked with that of Prof. Elihu Thomson in connection with the well-known dynamo and arc lamp. These gentlemen have decided to establish in Philadelphia a firm of electrical experts to be known as Houston and Kennelly. We wish Mr. Kennelly success in his new undertaking.

The Waterloo and City Railway.—The Waterloo and City line, which will afford a much-needed connection between the terminus of the London and South Western and the City, bids fair to be the first completed of the several underground railways, plans for which are more or less advanced. The London and South Western Company has agreed to work the line for the owners taking as remuneration 55 per cent. of the gross receipts, and guaranteeing to the new Company a dividend of 3 per cent. on the investment, while any profits above the sum necessary to pay this dividend is to be divided in the proportion of one-third to the shareholders of the London and South-Western, and two-thirds to the new Company.

Electric Lighting of Forli.—The electric lighting plant at Forli, a town on the Adriatic side of northern Italy, has the almost unique distinction of consisting of exclusively Italian materials and machinery. According to a notice in *L'Elettricista*, the power is obtained from the fall of 2,000 litres of water per second through a distance of 4 metres, which works a Girard turbine constructed by Alberto Riva, of Milan. To meet the necessities arising from insufficient water supply a compound condensing 50-H.P. steam engine, by Messrs. Tosi, of Legnano, has been added to the plant. Two shunt-wound dynamos, one of which is held as a reserve, both giving 100 amperes and 160 volts, supply the current, either direct or through accumulators. The latter consist of 88 cells of the Tudor type, constructed by the Fabbrica Nazionale of Genoa. The battery is capable of feeding 250 16-candle lamps. The distribution is at present arranged on a system of two wires, but the great demand which has grown for the supply of electricity in the town has made the adoption of a three-wire system a matter of urgent necessity.

Railway Telegrams.—In the House of Commons, on Monday evening, Sir J. Fergusson asked the Postmaster-General what was the present position of the negotiations with the railway companies for limiting the increase in the number of telegrams which the companies were entitled to send over the public telegraphs free of charge ; and whether the arrangement with the Midland and the Manchester, Sheffield, and Lincolnshire Companies, announced by the Postmaster-General on February 27, 1893, had now been adopted by the companies generally ; and, if not, whether, in fairness to the companies which had come to terms, as well as in the interests of the public, he would take steps to ensure an early and complete settlement of the question. Mr. Morley stated in reply that since the date of his reply to a similar question in February last several important railway companies had entered into agreements similar to that concluded with the Midland and the Manchester, Sheffield, and Lincolnshire Railway Companies. Negotiations were pending with the London and North-Western, the Great Western, and other large companies, but he regretted to say that these companies had not yet seen their way to accept such terms as he had felt able, in justice to the public

Digitized by Google

interests, to offer. He agreed that it would not be fair to the companies which had entered into agreements on the subject that a settlement with the other companies should be indefinitely postponed; but he trusted that a spirit of accommodation would prevail on the part of these companies, and that exceptional measures for the protection of the public revenue would not become necessary.

Electrical "Private Views."—"Misconceptions," says our New York contemporary, the *Electrical Engineer*, "are very common as to the apparatus and *employés* that come in between the parties to telephonic conversations. Any intelligent effort to remove some of these misconceptions is to be applauded, and an interesting example comes to hand in the novel policy recently inaugurated by the management of the Metropolitan Telephone and Telegraph Company in inviting its subscribers and their friends to view the new central office in Broad-street, New York. A few days after the exchange was opened a general invitation was issued to the Broad-street subscribers. During the two afternoons appointed nearly 500 telephone users made a tour of inspection under the guidance of the Company's staff. The usefulness of such an object lesson was abundantly illustrated by the comments of the visitors, most of whom were entirely unprepared to encounter such a display of highly-finished and intricate apparatus, or such a numerous and industrious operating force. Many subscribers resolved on the spot, after watching an operator handle half-a-dozen calls in ten seconds, never to swear at 'central' again, and some even declared that they would cease grumbling about the rates, so obvious did it appear that there really were other items in the cost of telephone service besides the set of instruments at the subscribers' station."

Obituary.—Mr. Henry Vernon, one of the oldest pioneers of telegraphic engineering, died on Tuesday, the 20th ult., at Weston-super-Mare. Mr. Henry Vernon, better known to telegraph engineers of 50 years ago as Henry Vernon Physick, was born at Bath on March 14, 1814. He was at one time at Fox's, Birmingham, and was afterwards in the office of Mr. George Parker Bidder, C.E. He worked here with Mr. Austin, who married a sister of Charles Dickens, and as Mr. Vernon lived with Mr. Austin he became intimate with the family of Mr. Dickens. He was one of the earliest workers on telegraph lines, and put the wires along the Blackwall railway in iron pipes. Afterwards he was for several years assistant engineer to the Electric Telegraph Company, Mr. Hatcher being the engineer-in-chief. In 1850 Mr. Hatcher was succeeded by Mr. Edwin Clark, and Mr. Physick by Mr. Latimer Clark. Mr. Physick then took to contracting, and taped, tarred, and sanded all the gutta-percha covered wire used in the four cables between Ofordners and Holland in 1853. He executed large orders for stores and instruments for the Indian Government, and various Colonial and foreign railway telegraphs. He was the inventor of the first insulator that had any attempt to make a shelter groove round to keep a dry zone. This was patented in the joint names of John Lewis Ricardo (chairman of the Electric Telegraph Company) and Mr. Henry Vernon Physick. The insulator was used on many lines in England, and if we mistake not on the land lines through Corsica and Sardinia for the Mediterranean Telegraph Company. Mr. Henry Vernon, who discarded the name of Physick, retired many years ago to Weston-super-Mare. He was a thorough mechanical engineer, and had a room in his house fitted with numerous working models of steam-engines and steamboats.

Sun-spots and Magnetic Disturbances.—The *Memoirs* of the Società degli Spettroscopisti Italiani, Vol. XXII., p. 189, says *Nature*, contains a Paper by Dr. L. Palazzo on the magnetic disturbances of August, 1893, considered in relation to the extent of solar spots. When the very large spot, or rather group of spots, was passing the central meridian on August 6th and 7th of last year, the bifilar magnetometer of the Roman College Observatory was considerably disturbed. On August 18th, that is, when the spots were again near the plane of the central meridian, but on the other side of the sun, all three magnetic elements suffered a disturbance. Another magnetic storm was recorded at the Marine Observatory of Pola on August 12th and 13th. Dr. Palazzo has collected all the facts connected with these three disturbances, and discusses them with the idea of determining the relation, if any, between them and sun-spots. The disturbances of August 12th preceded by about twelve hours the transit of the largest spot visible upon the sun at the time. On August 18th, however, no spot could be seen near the central meridian when the magnetic needles were recording a perturbation, while neither when the double spot again appeared on the sun's limb, nor when it passed the central meridian on September 2nd, did the magnetic needles flutter. We have, therefore, spots without disturbances, and disturbances without spots, thus indicating that the connection between the phenomena is by no means a simple one. Prof. Ricco's discussion of the relation between solar spots and disturbances of terrestrial magnetism (*Mem.* degli Spettrosc., Vol. XXI., p. 153, 1892) led him to believe that magnetic disturbances occur, on the average, about 45·4 hours after the transit of spots over the central meridian of the sun. M. Marchand (*Comptes Rendus*, 1887, p. 133) showed that such disturbances occurred when groups of spots or faculæ were near the centre of the sun's disc, and Dr. Veeder has given evidence to prove that the appearance of spots on the sun's eastern edge is the signal for magnetic fluctuations. Dr. Palazzo, however, believes that the position with respect to the earth of the solar region disturbed is really unimportant.

Internal Combustion Engines.—A Paper on this subject was read before a recent meeting of the Graduate Section of the Institute of Engineers in Scotland, by Mr. P. F. MacCullum. The first portion of the Paper dealt with the amount of energy per pound of coal obtained by the earlier and the very latest forms of steam engines. It was stated that, early in this century, there were steam pumping engines at work in Cornwall indicating a horse-power for about 2lb. of coal per hour, and that at the present time the very best marine engines required 1¼lb. of coal per indicated horse-power per hour. The history of gas and petroleum engines from the earliest times was then sketched, and the determination in more recent years of gas engines into two distinct types pointed out. The first class included those working on the four-stroke cycle, invented by Beau de Rochas, and brought into practical use by Dr. Otto. The second embraced a large variety of motors, which might generically be called "displacer" engines, employing a separate pump to draw in the charge of gas and air, which was then used to force the waste products out of the combustion cylinder. Apart from the increased complication of this type, the almost impossibility of expelling the waste products without losing some of the fresh gas made these engines inferior in economy to Otto engines, the general superiority of the latter being convincingly shown on the expiry of the patents by the almost universal adoption of the four-stroke principle by gas engine makers. A very simple form of vertical displacer engine, made by Messrs. Day and Co., was described as being free from many of the defects of this class, and it was shown that but for the difficulty of preventing some loss of gas when expelling the waste products, there was no reason, practical or theoretical, why such a motor should not work as economically as an Otto engine, and moreover give an impulse at every revolution. Producers for converting solid and liquid fuels into gases suitable for use in gas engines were next described, the calorific losses due to the conversion processes for coal or oil being stated as about one-third of their total heat-energy. Oil engines of the vaporiser type were described as modified Otto gas engines, and the average consumption of ordinary commercial petroleum per indicated horse-power was stated as 0·6 to 0·71b. per hour. Gas engines using oil gas made in a special apparatus appeared to require about 0·91b. of oil per indicated horse-power, including an equivalent of oil for the fuel consumed in the gas-making operation; so that oil engines have a considerable advantage in economy, and at the same time require no subsidiary plant. In oil engines the author considered that considerable loss of fuel resulted from condensation of vapour on the cool walls of the cylinder during compression, and the initial sudden expansion of the gases at the moment of ignition. Still the oil engine worked with great economy, and formed the most convenient motor for moderate powers wherever cheap gas was not available.

MAGNETISM AND THE MAKERS OF IRON.

BY SYDNEY EVERSHED.

When Tubal-Cain accidentally puddled a pot of molten iron into a usefully tough and malleable mass, he unconsciously laid the foundations of an industry which has lasted with but little change in methods until our own day. The craving for blood, so characteristic of the descendants of Cain, acted as a powerful stimulus to invention, and in steel a third variety of iron was soon recognised as possessing highly desirable qualities; but there invention ceased, and the art and mystery of workers in iron was handed down from generation to generation, becoming, in the course of ages and with the growth of mechanics rather less of an art, and with increase of knowledge more of a mystery.

But while the operations of iron manufacture have in essentials remained without change for thousands of years, the applications of iron and steel have steadily, and of late rapidly, increased in number, and magnitude, and complexity. The modern blast furnace is only a larger earthern pot in a fiercer fire; the steam hammer is merely a stronger and heavier stone; but in the nails and swords made in the days after the bronze age we can hardly see a germ of our ironclads and Forth bridges. These larger works have compelled attention to the chemistry of iron in relation to its strength; but having once for all discovered the right process for producing material of definite mechanical properties, the manufacturers have, for the most part, resumed their traditional attitude as masters of a traditional mystery; and so it comes to pass that when called upon by a new and strident industry to produce iron with new qualities having no apparent relation to those concerned in mechanics, their first impulse is to pacify the fractious infant with smooth words, or a *non possumus*; and their second to ask, very meekly, "What is permeability? What hysteresis?" The reply being practically incomprehensible, they very naturally say, "Tell us what sort of iron, what percentage of carbon and so on, will produce or annul those incomprehensibles?"

Is electrical engineering in a position to do this? We fear not. The last meeting of the Institution of Electrical Engineers emphasised the fact that we are not yet agreed about the best means of detection and measurement of the magnetic properties of iron, much less about their explanation in any rational or even empirical manner. We know that permeability and purity go together to some extent, but even here cast steel is a stumbling block. So also presence of carbon, and "hardness"—whatever that may be—imply large coercive force, and therefore hysteresis; yet pure electrolytic iron is by no means free from coercive force—it may be worse in this respect than mild steel. In short, present knowledge of the subject is just that mass of detached facts which precedes useful and sometimes splendid generalisation. The facts are almost ready for marshalling, but where is the marshal? It must be confessed that the accumulation of facts tends to outstrip sound generalisation, and especially is this the case in branches of science on the borderland of physics and chemistry. The temptation to discover new phenomena, a "Smith effect," or "Robinson effect," or to add one to the host of compounds belonging to the "Benzene ring," seems well nigh irresistible to our physicists and chemists, and so we must wait, and keep the manufacturers of iron waiting, for a rational explanation of the true inwardness of the iron molecule. Until a seer is forthcoming we must be content to blunder along more or less in the dark.

The darkness is, however, no excuse for hazy notions of the tendency of well-ascertained facts. The experimental work of the past few years, so far as it relates to the phenomena of magnetic hysteresis in iron, has cleared up many obscure or doubtful points, and one step in the way of generalisation together with one experiment by way of confirmation, have practically removed all but the last veil between us and the reality. Prof. Ewing having shown that, theoretically, no artificial control of molecular magnets was needed to explain the observed facts, Mr. Capstick made a model of a piece of iron by grouping together twenty-four little pivoted magnets. We have the cyclic curve of magnetisation obtained from this crude and excessively simple model of molecular structure before us as we write, and its perfect agreement with the cyclic curves obtained from groups of millions of molecules, points so clearly to a simple explanation of hysteresis as a phenomenon quite apart from chemistry, that we feel bound to warn manufacturers of iron that the hope held out to them during the discussion of Mr. Kapp's paper—the hope that by further purification they might eliminate hysteresis entirely — is almost certain to prove illusory. Before Dr. Fleming encouraged the iron makers to purify and purify until hysteresis was gone, he should have shown us how to eliminate hysteresis from Mr. Capstick's four-and-twenty magnets. There is no question of chemistry indeed it is difficult to see anything more abstruse than geometry in the model. The size, shape, and relative positions of the little magnets obviously affect the magnetic cycles, but the constitution of the magnets themselves, so long as they are practically permanent, must be a matter of indifference. We must not be understood as saying that the chemical composition of iron plays no part in its magnetic behaviour, the presence of carbon, for example, has a marked effect, but the Ewing-Capstick model does seem to us to prove conclusively that hysteresis is a property inherent in a group of magnetic molecules; it exists by reason of their mutual attractions as magnets; abolish it and the magnetism of the molecules goes with it. Small quantities of carbon, if in combination, may conceivably alter the structure and shape of the molecules, and if free may merely clog them; in either case an increase of coercive force is quite probable.

For the present, then, makers of iron must look for little help from electrical science; let them purify iron as far as possible, and above all endeavour to supply quantities of uniform quality—a matter of far more importance to electrical people than absolute purity. To the builders of dynamos and transformers we can only say—test, test, test! Buy from a tested sample, test the bulk supplied, buy from the maker if you can, and remember that the middleman is in the iron trade generally a muddleman.

AN EVAPORATIVE COOLER FOR CONDENSER WATER.

In the course of the discussion on Prof. Robinson's Paper on the electric lighting of St. Pancras, recently read at the Society of Arts, Mr. Druitt Halpin described a system of condensation he had lately seen on the Continent, which he thought would be very suitable for stations working in towns where condensing water was not available, and where the nuisance caused by steam passing off was very great. In this plant the whole power to be provided for was about 10,000 to 12,000 h.p., and when he saw it at work already between 2,000 and 3,000 h.p. were actuated by it.

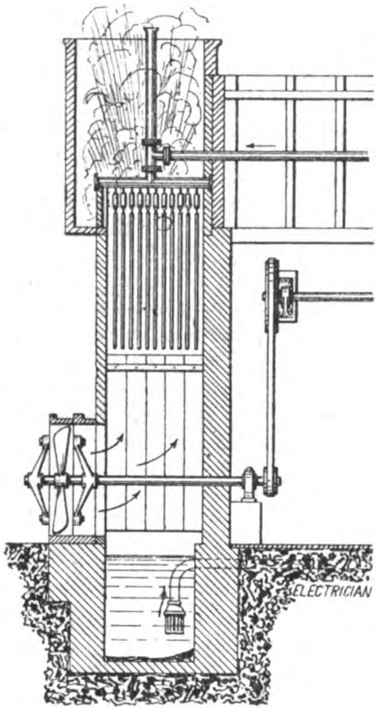
The arrangement consists of an ordinary jet condenser worked by a special engine, and dealing with the steam from a number of engines about the works. This jet condenser only had a supply to keep it going for about ten minutes, and after the water had been warmed by passing through the condenser it was pumped up to the top of a light wooden building, and then ran down over boards placed vertically, adhering to the surface of the boards by capillarity. The boards were in two lengths, the upper and lower lengths being placed at right angles to each other, in order to ensure the water being broken up. At the bottom, air was driven into this structure by a fan worked by the same engine which actuated the centrifugal pump for lifting the water from the tank in which it was received from the condenser to the top of the boards. This air passes up between the boards, which are a slight distance apart, and effects the cooling partly by carrying heat away and partly by evaporation.

The water was cooled to about 80°F., but it was found that this water was capable of producing as good a vacuum as water ordinarily does at a temperature of 50 to 55°F., and this can easily be explained by the fact that this water is almost completely devoid of air; passing through and through the condenser continually the air is taken out, and when passing

Digitized by Google

through the arrangement of boards the air pressure is so slight from the fans and the time is so short that there is no opportunity for it to absorb air again before retiring into the condenser.

The quantity of water carried away in evaporation by this arrangement was about half the total quantity of feed water



An Evaporative Cooler for Condenser Water.

passing through the engines, so that a quantity of water equal to about half the volume of the feed water had to be continually run to waste to prevent an undesirable accumulation of water. As the whole of this apparatus is so very light, cheap, and simple, Mr. Druitt Halpin thought it was specially adapted for placing on the roofs of central stations in London and elsewhere in order to obtain the economy due to condensing, and also to avoid the nuisance of steam passing into the atmosphere.

SOME NOTES ON THE ELECTRIC LIGHTING OF THE CITY OF LONDON.*

BY MAJOR-GEN. C. E. WEBBER.

(Concluded from page 453.)

It being very desirable that the works of distribution in the City should receive efficient criticism, Professor S. P. Thompson was (at my suggestion) asked, in October, 1891, to advise and report, which he did ; and I regret that circumstances permit me only to give the sense of his reports. He dealt with the subject of any possible advantage from the use of low-tension dynamos and step-up transformers at the generating station, in comparison with the generation and transmission at 2,000 volts as specified, without recommending any change in the designs. He recognised the extreme difficulty, in certain thoroughfares, of getting ways for the laying of conduits ; in certain rich blocks, of getting a cellar for a distributing station ; and the necessity for the principle routes to run north and south, not east and west, because the generating stations were on the south side. As an example, he regarded Cheapside as practically an impassible street ; as it runs east and west, "as almost useless for the purpose of a route." That shops in it must be approached through side streets and from the rear he considered in reality as no disadvantage, "for lamps are wanted most, not in mere frontages, but in back offices." He thought that there was the less need in the central areas to trouble about keeping them of equal size, since the distances from one sub-station to another were necessarily short. Having secured a sub-station in any one spot, it was easy to estimate, from the accommodation it affords, the extent of the district which it will subserve. He told me that the general plan I had prepared of distributing the alternating current at a pressure of 2,000 volts by mains to transformer sub-stations "could not be improved upon," and agreed entirely in principle with the general plan of distribution as provisionally set out in the maps shown ; and, further, approved generally the size of areas assumed in those maps to be suitable, and that the richest areas so mapped out are the eight areas surrounding the Mansion House (see plan, Fig. 19) marked respectively C^1, C^2, C^3, C^4, and E^1, E^2, E^3, E^4. The diagram map shows eight central districts in the City which were presumed to be those richest and having the largest immediate demand. He agreed entirely with me in deprecating the provision of mains, through long streets, as had been laid out in the pioneer contracts, and saw the need to break up long streets into sections, each such section to be supplied as part of a compact surrounding area. The exact delimitation, even, of the individual areas he considered a less important matter than their compactness, solidity of work, and efficiency of supply. At that time, and with the same gentleman, the question of automatic switching of a bank of transformers was discussed. It was a novel one as regards experience. We regarded it as essential that, although at first manual regulation with daily shifts of attendants could not be avoided, eventually it would have, for economical reasons, to be done automatically. And in connection with this the inventions of Messrs. Gordon, Mordey, Tomlinson, Ferranti, and Kapp were considered. Of these well-known electrical engineers some are present, and will, I hope, give us the benefit of their remarks on this very interesting and important part of the subject.

Execution of the City Street Work.

Although it may not fall to the lot of any present to have to carry out a similar work under the same conditions, it seems to me that a short account of a portion of what was done in the City streets may prove instructive to engineers. Our papers are generally very full of technical interest, but few ever narrate the practical working engineer's experiences. This must be my apology for some diffuseness. Enforced inaction for an engineer is always irksome especially as he is well able to anticipate the loss and overwork that must follow through dilatoriness of those whose duty it is to make up their minds. Such was my position between July and December, 1891, when valuable time was lost, and heavy and pressing work requiring to be completed by the end of February, 1892, had to be suddenly put in hand. Fortunately, I had foreseen the rush that would come, and had engaged and organised my office and staff so as to be ready to go to work when required, and had also called for and received tenders for the various kinds of articles of plant and materials (several of which had to be specially designed) that the work would require.

The chief difficulties that had to be faced, besides those inseparable from street work in the City, were—(1) the time of year (all the fine autumn had been lost), with its wet, mud, and fogs; (2) the difficulty of readily finding a sufficient number of suitable foremen to take charge of such work ; (3) the inconvenience caused to the public by having 100 yards of footway "up" in nearly thirty different places at one time. My estimates of the cost of the work had been based on the assumption that it would be carried out under our own staff, by hiring labour, and by purchasing tools and material, with a reasonable rate of progress. There was no doubt whatever that the intermediary of contractors would be wasteful, even although it was easy to find road and paving contractors in every city of the kingdom. Time being precious, and the Commissioners threatening, my ideal could only be partially carried out. Tenders had, therefore, to be called for for separate sections of the obligatory streets ; but here the obvious difficulty of price had to be faced. No contractor would quote to lay anything under a City footway without at least 100 per cent. margin, unless he could first take up the surface. But this first taking up was not permissible. Tenders under such conditions were obviously objectionable. Then, considering that we wanted several contractors to go to work at once, besides our own gangs, it would have sent the price up a hundred-fold if their tenders were to include the supply of tubes, cases, and material, because they would have been competing for such unprecedented quantities in the same market. There was only one course to follow, namely :—(1) To purchase all the materials ourselves ; (2) to prepare a specification and schedule of measured prices especially suitable and confined to the kind of work ; (3) to pay for the work under measurement.

As regards the first, namely, the material : wrought-iron tubes, although a considerable stock is to be found amongst makers, are not held in quantities representing hundreds of miles, particularly of the quality of iron, and lap-welded, that we wanted. Our tests of samples were necessarily hasty ; but the steam hammer, though rough, gave us a pretty fair indication of toughness. The very fact of so large a quantity being wanted, instead of enhancing the price, enabled us to do what is called "break the ring," and I believe it is one of the very few cases in which tubes have been sold some 20 per cent. below "ring" prices. All the tubes were treated with Angus Smith compound. As regards the Callender-Webber casing,

* Paper read before the Institution of Electrical Engineers, February 8, 1894.

Digitized by Google

there was only one maker; but here, again, foresight on behalf of the City lighting had a long time previously provided for special rates in favour of that particular work. At the same time, I cannot speak too highly of the great efforts of Mr. Tom Callender at that time to extend his company's means of output, and that at very short notice. I remember that at one time the bitumen we were bound to lay underground in January, 1891, was still, in Christmas week, 1890, on board ship in the chops of the Channel.

As regards the second, namely, the specification and schedule (of which a copy may, if the Council permits, be attached), it is sufficient to state the former consisted of 44 clauses, and that the latter had 55 items, which the tendering contractors were asked to price. But even with these precautions it was felt that, in the case of the most difficult streets, no contractors could be asked to tender at all except they were allowed to charge for whatever they paid out, and then with no obligation to meet all the liabilities for damage to person and property in the most crowded and intricate places in the whole world. To our own engineers and men the work in such places as Cannon-street, Thames-street, Cheapside, Poultry, St. Paul's-churchyard, and around the Bank, &c., was allotted. In the 22 streets in the eastern and central districts which remained to be dealt with at the end of December, the total length of trench to be excavated, and completed with conduits and boxes, was nearly 24,000 yards, of which 9,700 was allotted to the company's that, if the adverse conditions I describe could have been avoided, a saving of about £7,617 on what actually cost over £30,000 would have been effected; and that is exclusive of the advantages in the minor results in the form of better "finish" when the work is done under one's own foremen. If the same work had been carried out at the rates of the highest tenders accepted it would, including material, have cost £72,000; and if entirely in the way my estimates contemplated, the costs would have been, correspondingly, £40,000. But in neither event, having been begun in December, would it have been all done, as was essential, early in February.

A glance at the map (*see* Plan 19) will show that in the heart of the City there are eight transformer areas designed; and, naturally, as soon as the main thorougfares were completed, to the completion of conduits in the lesser thoroughfares, streets, and courts of these areas was immediate attention turned.

The amount that had to be paid for the work done in the streets by the pioneer contractors (already referred to) was £22,850, which, added to the previously-stated amount, came to a total for the main thoroughfares of the eastern and central districts of £81,850. In the whole City there are 92½ miles of frontage, and in the eight special areas there are 22,000 yards. If the average demand for lamps is 2·1 per yard, we get 42,600, or about 6,000 per sub-station area; but, being the richest areas, three lamps per yard, or 8,500 per acre, was estimated. By March, 1892, the

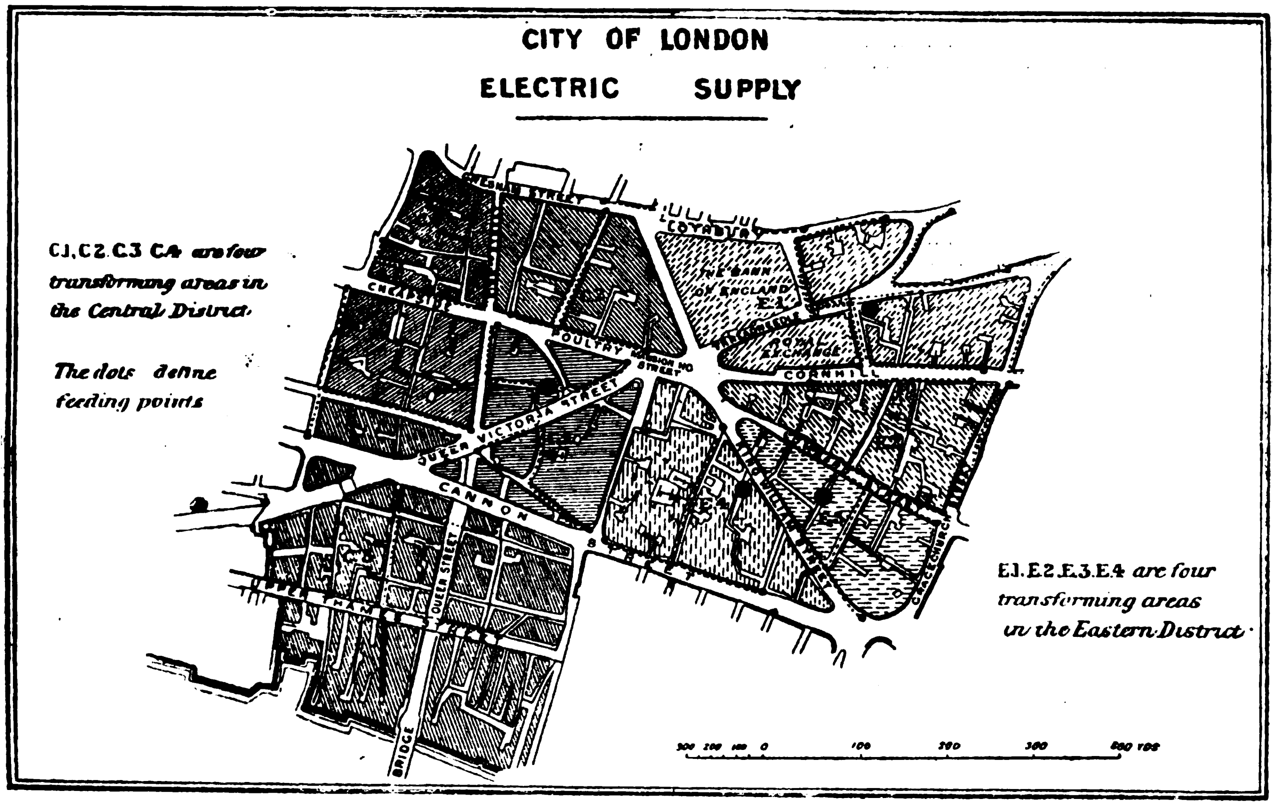


FIG. 19.—Centre of City.

gangs. There was only one month to do it in to carry out the conditions of the contracts with the Commissioners. Three contractors at first—afterwards a fourth was added—competed successfully.* The abstracting of all the tenders showed a variation on the average work between £188 the highest and £79 the lowest, per 100 yards of work. The highest tender accepted was at the rate of £128 per 100 yards. The same work in the more difficult ground done by the company's gangs cost only £60, including the cost of the plant used by them. The average cost of the materials was about £118 per 100 yards. The actual cost of the work essential to be completed in February was about £59,000. The maximum rate of progress was attained at the beginning of March, 1892, when 1·65 miles of trench was completed in six days' work.

An analysis shows that the 4,260 yards by one of the contractors, at £128 + £118 = £246, cost £3,069 more than it would have cost if done by the company's gangs; that the 4,010 and 5,270 yards of the two others respectively cost £2,560 and £1,265, correspondingly, more; giving a total of £6,894. But it may fairly be said that, if the contractors had tendered to do the work when the days were fine and long, their prices would have been 5 per cent. less, say, £723. It may be instructive to young engineers present to realise cost of the work (not done by contract) could be pretty closely detailed, and the cost of the conduits in portions came to a little over £17,000; giving a total for the completed street work in the main thoroughfares and eight sub-districts of the eastern and central districts, exclusive of conductors (except a small quantity of cable provided under the pioneer contracts, which is included), of £98,850. Of this, the length of trench completed by July, 1892, was 43,000 yards. I have little doubt we shall be told that most of the lighting in those areas is with 16-c.p. lamps. In this respect, I think it is evidently the wrong initiative policy to try to make up a big load before you are ready in order to make a fair show, instead of keeping it down when first starting by encouraging in every possible way an economy of light by the use of 8-c.p. lamps. It is well known that I have been from the first an advocate of this policy, and I now attribute our measure of permanent success at Chelsea as being largely due to it.

It will be readily understood, by a glance at the plan, that the streets bounding the areas having been completed with all the "ways" actually necessary, and that could be put in, the internal cross streets could be provided with all that the future load could possibly demand for feeders of any size.

A more precise idea of the cost of this kind of work laid in streets presenting exceptional difficulty is given below. In an example of

* Nine firms tendered.

Digitized by Google

the streets in question only eight "ways" could be introduced under the footways on each side, viz. :—

	Ways.
In Callender-Webber casing	3

In 2½in. „	1
Total	8

The length of the two sides, taken together, inclusive of the lengths occupied by boxes, is 1,328 yards.

The cost of taking up the surface and temporarily relaying it, at 3s. 9d. per yard lineal, was	£250
Laying conduits and pipes, at 1s. 3½d.	85
Cost of „ „ at 8s. 6d.	718
Superintendence, storekeeping, cartage, sundries	78
Small stores and blacksmith's work	27
Wear and tear of plant, and contingencies	116
Cost of draw-boxes and service-boxes where actually required	99
Approximate cost of restoring the surface) performed by the Commissioners' contractors, and on their schedule	554
Total	£1,927

Or £1. 9s. per yard lineal of trench, exclusive of cables.

The equipment of this line with cables of the following sections, namely :—

2 of 0·3 square inch section of copper	} for low
1 of 0·15 „ „ „	} pressure,
4 of 7/16's	} for high
1 of 0·158 square inch (concentric)	} pressure,

costs, in addition, £2,037, giving a total cost per yard lineal, inclusive of cables, of very nearly £3.

Including casing used for house services, the total length of ways in bitumen concrete casing laid in the streets and areas named up to July, 1892, was

In casing unsheathed with iron	4,356 yards
„ sheathed in iron	148,068 „
Total	152,424 „

Or over 80 miles.

The internal diameter of these varied between 1in. and 2⅝in. The largest proportion of these were of the triangular form. The total of 1¼in. wrought-iron tubes laid was 173,000 yards, or 98 miles; of 2½in. wrought-iron tubes, 164,000 yards, or 93 miles. Total of ways of all sorts laid in the City between December, 1891, and July, 1892, 271 miles.

Of the Raworth-Callender-Webber conduit, 212 yards, containing four ways, were laid in Queen-street. This was an experiment, and is an example of paper-lined ways bedded in bitumen and lying in cast-iron troughs, with separate cast-iron joint-pieces, and cast-iron covers bolted down.* The durability of the paper has yet to be tested, but of this I have little doubt, if it is thoroughly impermeated; the only drawback is that they cannot be easily bent during laying, and that, as laid in the City, the cast-iron cover has to be cut through with a cold chisel to make a house service connection.

The sheathing of the Callender-Webber cases was mostly made of No. 22 gauge sheet mild steel, which covered the three sides of a triangular and the four sides of a retangular case, then secured by studs or cut-in pieces, or 1½in. hoop iron riveted, and the whole painted over with a bitumen solution. Sheathing for these cases was first used in the City work. As is well known, the cost of the casing when it is triangular in section and has three ways of 1¼in. diameter each is, without sheathing, 1s. 11d. a yard, which is 7⅔d. for each way; the same sheathed costs 2s. 10d., or 11⅓d. per yard. Nearly all the 1¼in. wrought-iron tubing laid (generally four tubes under each footway throughout)† cost 9½d. a yard, which was an exceptionally low price, for the reason I have already given; this is, against the first cost per yard of ways of the former material, less by 1⅚d. per yard. The advantages of the bitumen case, I think, more than counterbalance this: (1) durability; (2) there is less labour in making two bitumen joints than three screw joints (the former are 6ft. apart, the latter 12ft.); (3) the bitumen is more easily cut to lengths and bent than the wrought iron; (4) there is no risk of rust sealing in the cables after they are in the bitumen ways, as often occurs with iron ways.

* This latter system, called the "Callender-Raworth-Webber," in which I am joined with those gentlemen by an act of courtesy on their part, is chiefly attractive to me through the possibilities it offered for the use of bare stranded copper. Since then I have brought out, in conjunction with those gentlemen, a further development, being a combination of the two systems above mentioned, called the "Webber-Callender-Raworth" conduit, which I hope may be a step in advance in that much-to-be-desired direction.

† Two 1¼in. tubes are destined for the public, and two for private arc lighting series cables.

When you come to compare the 2½in. ways in bitumen and wrought iron, the costs are as follows:—In the former each way in a *sheathed* case costs—

	Per yard. s.	d.
With triangular section, three-way	1	9⅓
With rectangular section, „	2	1

This at once compares favourably even with the exceptional low cost of our 2½in. wrought-iron tubing used in the City, which was 2s. 6¼d. And when there are six 2½in. ways in a case the cost per way comes out 1s. 5d. per yard, and a large economy is at once evidenced (increased if the cost of sheathing is avoided). But it must at the same time be noted that where we laid 18 (and more) 2½in. tubes in the same trench with other conduits—for instance, throughout Thames-street—we might not have found room for three more six-way cases, which in cross section occupy more space than 18 2½in. tubes.

I have not referred to the western district, the contract for the public lighting of which did not require completion before November 5, 1892; but it may be stated that this work alone required 11,614 yards of trench, which, at an average cost of £1. 12s. 1d. a yard, would cost £18,630, exclusive of spare tubes for other purposes.

CONDUCTORS.

As has been stated, the primary alternating-current conductors were concentric 0·154in., with high-class insulation; the high-

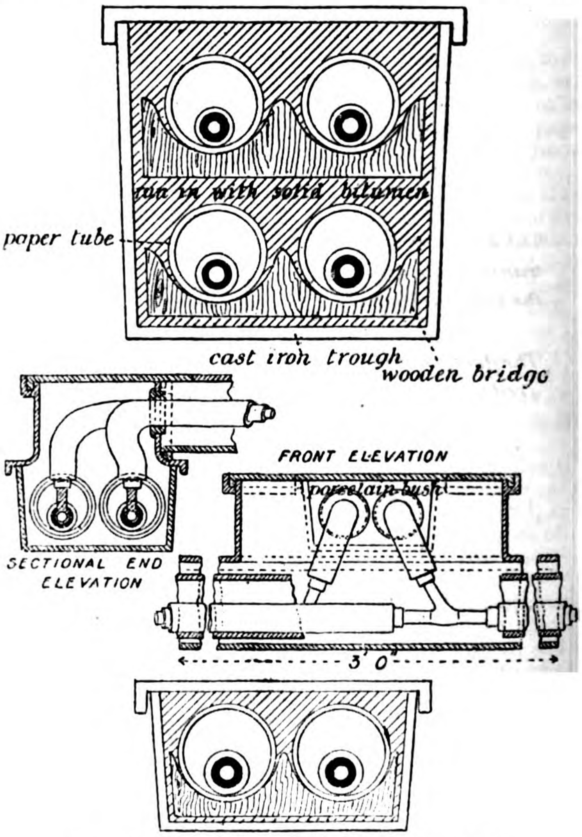

FIG. 20.—Callender-Raworth-Webber Conduits.

tension continuous-current conductors were 7/16's concentric, except where the lamps are connected, also with high-class insulation; and the secondary conductors on the three-wire system of various sizes, has Callender extra standard type insulation. The two first were drawn into 2½in. and 1¼in. wrought-iron tubes respectively. The last was drawn into the three-way Callender-Webber casing, manufactured of three sizes, namely, with 1½in., 2in., and 2⅝in. ways; in each of those the third way is smaller than the other two. The largest were for feeders where necessary, and the two smaller for distributors.

In the eight sub-district areas shown on the map (plan No. 19) it is seen that no consumer's terminals would be more than 100 yards, measured along the main, from a transformer station; consequently, allowing the Board of Trade drop of 4 per cent. above and below the normal, the section of cables first drawn in, the maximum areas of the three conductors, taken together, was five-sixths of an inch; and very few feeders except quite short lengths were necessary. It was considered that for a considerable time to come this would comply with a demand of at least three lamps per yard of frontage, the frequency of transforming stations being maintained. The impedance due to retardation was, therefore, negligible with those sizes.

Digitized by Google

The cable specifications giving the special conditions under which the manufacturers had to tender (of which a copy will be attached to this Paper) had some special features, namely:—The same results of insulation as were prescribed for the tests at the maker's works were required after each length of cable had been drawn in, in the presence of the maker if he wished it, and before joints were made in it. The maintenance of the insulation, except at joints, was guaranteed by the maker during three years from the date of it being drawn in, and if within that time the dielectric had deteriorated the maker was to replace the cable. With a view to the company having the advantage of the market rate of the price of copper at the date of the quotation, the contractor was required to state the number of tons of copper, made up in insulated cable, for which he would receive orders at that rate during one year.

As it became soon apparent that in each of the eight sub-districts above referred to separate transforming stations might not be obtainable, the question of a distance between them probably greater than had been calculated on required consideration, and the consequent enlargement of the sectional area of the copper in the conductors. The first point that had to be considered was as to the saving that could be effected by the use of hollow-cored cable. With alternating currents having a frequency of 100 there is an inequality of distribution of the current over the cross-section of the cable, and for practical purposes the penetration may be regarded as not exceeding $\frac{1}{4}$in. from the outside of a cable of stranded copper, and, therefore, if above $\frac{1}{2}$in. diameter, the copper in the centre of the strand is not useful. These conditions led to the adoption of the Callender hollow cables for sizes varying between 0·4 and 0·7 of an inch sectional area as the simplest and cheapest form. For instance, such a cable, having $\frac{1}{2}$ sq. in. section of copper, was made up of 38 No. 10's, or 30 No. 9's, in two layers, round a hempen core, when the outer diameter of the copper is 1·05in. For anything over $\frac{3}{4}$ sq. in. section of copper it was apparent that some form of multiple strand would have to be adopted; but for the supply then contemplated (even with only 600 amperes per square inch density) the maximum of 0·7 of a square inch was sufficient to provide.

As regards joints and jointing—that very important matter both in first cost and maintenance—I had examined every form that in 1891 had been before the electrical engineering world, and at that time had no reason to alter the opinion formed from long experience, that only when forced to adopt anything else by the construction or dielectric of the cable, could I recommend anything more simple, practical, or durable than the joint made of the same material and of the same form of covering as the cable itself; and this is applicable to both straight and T joints.

As regards the experience gained by the Company in the matter of their mains since July, 1892, I shall hope the Institution may have the most instructive information from the engineers who carried on the work after I retired from it. The best qualified is Mr. G. H. Nisbett, who since the autumn of 1890 had been my right hand in all matters connected with electrical distribution, and whose intimate knowledge of every part of the City work made it absolutely essential that he should pass from my service to that of the Company when I left it.*

Public Lighting—Lamps.

The lamp-posts and lanterns first erected in 1891 by the contractors, to the number of 72, in some of the main thoroughfares, under the pioneer contracts, did not meet with the approval of the Commissioners, and had all in time to be replaced. The only portion which was allowed to remain was the lantern which had been designed by the Brush Company, and which I have illustrated, and called the "Raworth" lantern. My own views had advocated a different shape, having a wide pagoda roof, and sides at smaller angle to the horizontal. In the case of the Raworth lantern, which is in use throughout the City, the dimensions were found to accommodate the Thomson-Houston arc lamp as well as that of the Brush. The interior is easily accessible; and the lamp, instead of being suspended, stands on a porcelain insulator. The other details are shown on the drawing. As regards glass, Colonel Haywood was very particular in selecting one that was least absorbent of light, while being sufficiently diffusive of the arc. The first sample, put in by the Brush Company, which gave the effect of there being four small blurs of light inside, was rejected as being too absorbing, and perhaps requiring too much labour in cleaning. Three samples of glass were submitted to the engineer, and tested by him in three street lanterns in use. They were respectively—

	Thickness. Inch.	Per cent. loss by absorption.
Ground glass	0·058	46·24
Opal	0·072	25·18
Rippled	0·145	21·73*

* I cannot refrain from also mentioning here two indefatigable assistant engineers on the same duty, namely, Mr. Buck (late R.E.) and Mr. Bates.

The last was approved, and is now in use, and is the cheapest.

The lamp-posts, as finally designed and approved by Colonel Haywood, are in two pieces, the base having two forms; the smaller base, which is round, is fixed in the narrower footways. As regards the shaft, one matter which required careful consideration was the means of assisting the lamp-trimmer to ascend and descend. In any case, fixed projections below the lantern upon which the man can stand at his work are necessary. These are the arms shown in the elevation. Fixed projections, or means of attaching them, were not admissible on the ornamental base; but something had to be done to assist the man to mount the shaft, so as to save the carrying and use of a long ladder in the streets. The permanent attachment of steps, for obvious reasons, the Commissioners would not allow.

Three methods were proposed, namely—

(1.) By the Brush Company, in which short pieces of rod iron, with a round head at each end, were passed into holes in the hollow shaft at intervals on alternate sides. These rods lay concealed—all except the heads—when not wanted; when in use they were pulled out as far as the head on the rod within the shaft would allow.

(2.) By Colonel Haywood, which consisted in a structure like a parallel ruler, concealed in and bedded in each side of the shaft. When shut up, no evidence of its existence could be seen; when opened, the whole has the appearance of a ladder with a centre stave, and, but for extreme complication and costliness, it might have been a very excellent design.

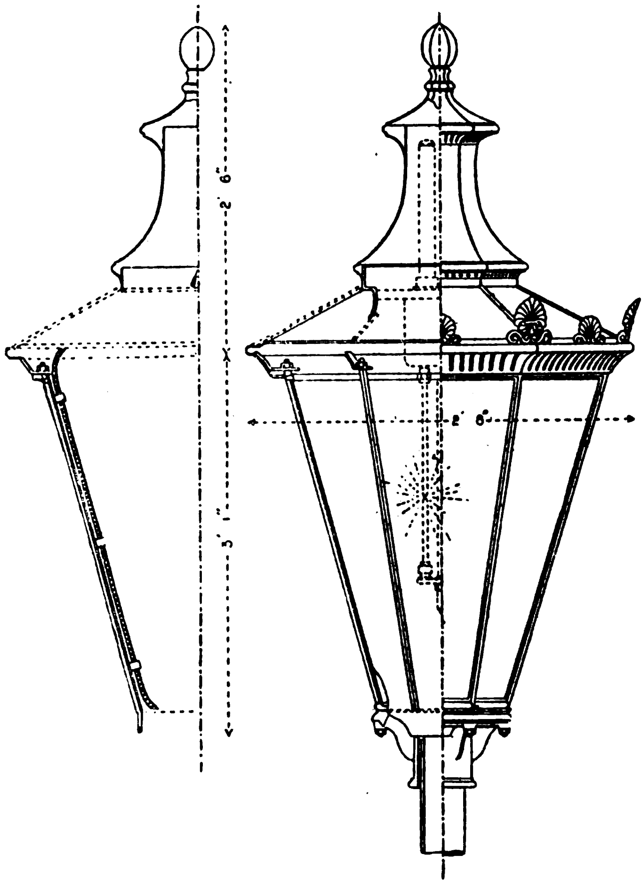

Fig. 21.—Street Lantern.

(3.) The plan which suggested itself to me was very simple, and has been adopted. It consists in using alternate side holes in the shaft, which are not conspicuous, and in having six or eight portable steps of light steel, which can be securely hooked into the holes as he ascends, and taken out by the trimmer as he comes down the post.

Where the footways are very narrow, and posts are inadmissible, it became necessary to use wall brackets; of one of these, illustrations in two aspects are given. The suspended lantern is the same in design as that on the posts, with some small differences in detail. It took a considerable time for the Commissioners to obtain the way-leaves for such heavy attachments to private buildings. The suspension gear was specially designed to allow the lamps to be independently and rigidly suspended inside the lantern, while the lantern itself is free to swing slightly and swivel round.

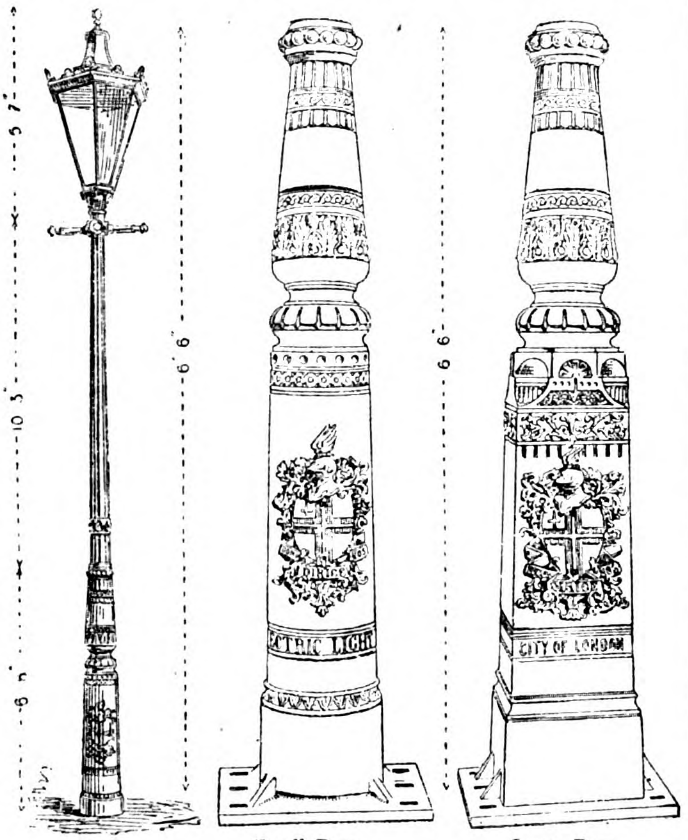
In both cases—namely, in the base of the lamp-posts and in a box fixed to the wall under the bracket—an absolute cut-out switch

* These tests were, I understand, made by Mr. Preece.

Digitized by Google

on an incombustible insulating base, approved by the Board of Trade, is provided. Each contractor has his own form.

In connection with fixing the posts more difficulty than might be expected was found. The base plates below the ground could not



Small Base. Large Base.

FIG. 22.—Lamp Posts.

be by any means uniform in pattern. It was impossible to tell before the ground was opened whether the posts could be solidly supported by a deeply set base, or by one that spread out under

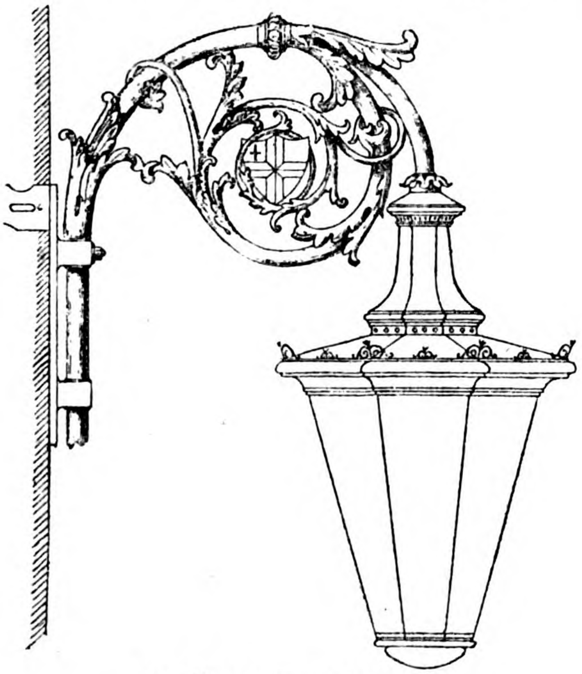


FIG. 23.—Lantern and Bracket.

the ground.* Several forms of modification of these conditions had to be provided for. In some cases heavy masonry and concrete had to be cut through and replaced. Of the 371 arc lamps contracted for in the eastern and central districts, in March, 1892, the positions of 340 only had been decided on. Of the 340 points 37 were brackets.*

The contracts with the Commissioners provide for the substitution at 906 points of glow lamps of not less than 200 watts† for gas lights throughout the City where arc lights have not been put up.‡ The contracts with the two manufacturing companies specify that they are to supply and erect 100- and 200-watt series glow lamps; all arrangements in connection with the first installation to be experimental. The carrying out of these arrangements are still in the experimental stage. The Commissioners had the power to compel the Company to complete them in the eastern and central districts by May last; but in withholding their engineer's order to have this done they have, I think, acted wisely in the interests of public lighting by glow lamps. At the beginning of this Paper I stated that the experiment on the Holborn-viaduct in 1882 had brought discredit on this means of public street lighting. The experiment now going on by the City Company in Basinghall-street is, I think, only calculated to produce the same result: but it is to be hoped the Commissioners will be as well advised in this matter as in the past.

The principles detailed by Mr. Trotter in his admirable Paper before the Institute of Civil Engineers on public lighting by electricity are equally applicable in the case of glow lamps as in that of arcs. His dioptric lantern, which we have known ever since the days of the Inventions Exhibition, is the mathematical example of

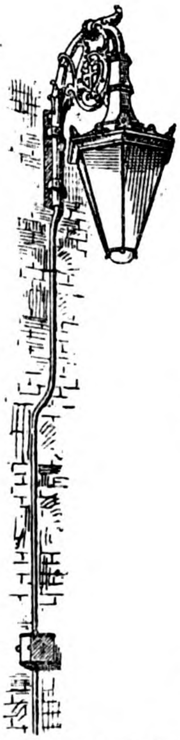

FIG. 24.—Lantern and Bracket, with Pipe under.

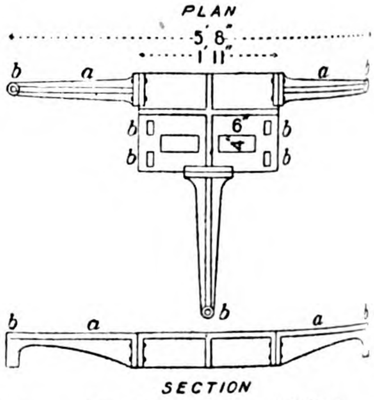

FIG. 25.—Underground Base of Lamp Post.

that for which he contends. It is many years since, at the Society of Arts, in a Paper on glow lamps, I demonstrated that the exposure of the filament to the eye, or the eye to the filament, is an abomination. I do not attempt to supplant Mr. Trotter's originality by showing a sketch of a street lantern with a hood, and inverted truncated glass cone underneath, the glass being cut up throughout a zone of its surface into diamond-pattern facets. There is nothing geometrical in their form (though there

* In erecting the posts extra expense was incurred through having to open the ground a second time after the trench for the mains had been made. The Commissioners were responsible for this, owing to delays in approving of the patterns, and in finally deciding on the actual points to place each post.

* The weights and costs of these posts, above-the-ground brackets, and lanterns, are as follows:—

	£	s.	d.
A large base weighs 9cwt. 2 qrs., and costs	£6	0	0
A small base weighs 6cwt. 3 qrs., and costs	4	10	0
Each shaft and lantern gallery weighs 3cwt. 1 qr., and costs	1	18	0
Each lantern weighs 3 qrs., and costs	7	0	0
Each bracket weighs about 1cwt., and costs	2	2	0

† The prices to be paid by the City for glow-lamp lighting is (sunset to sunrise)—

For a lamp of 200 watts .... £10 per annum.
" " 100 " .... 5 "

‡ It may here be stated that as early as 1888 every point in the City where arc or glow lamps would be likely to be required had been surveyed and plotted under my superintendence. The deviation from that design has been very small.

Digitized by Google

might be). They are only intended to intercept the direct view of the filament, within an area of space outside the lantern, and diffuse the rays of light from it. The simplicity of the design as regards convenience, &c., will, I hope, commend itself to the Commissioners, and I believe that, if posts in the small thoroughfares and courts were made entirely to disappear, and light, ornamental brackets, with lanterns such as I have illustrated, were used, the City would in this respect have also taken the lead, and have set a good example to all other municipal bodies.

This paper, as its title shows, only deals with a portion of the great work of lighting the City of London. Necessarily, my duties as engineer up to July, 1892, required my superintendence of the starting of many works at present far from completion; and while in every case I have been careful to avoid enlarging on matters which could be better described by the engineers more directly responsible, obviously there are also several matters which might be regarded as more or less confidential. These I have avoided, and in selecting illustrations from figures have confined myself to those previously accessible to the profession.

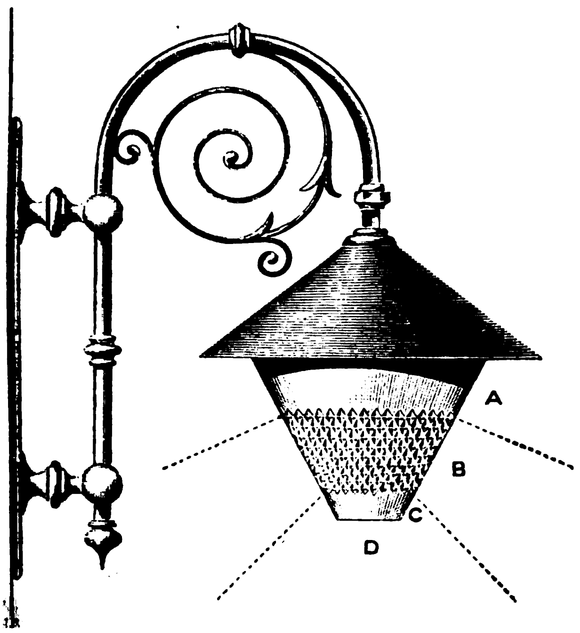

Fig. 26.—Wall Bracket, Glow Lamp Lantern.

In concluding, I hope I may be allowed to state that never was an engineer better served than I was by my staff, and that each and all fully justified their selection, equally those who were new to me and those who were old friends. It is no flattery to them to believe that my severance from the position of being their chief has in no way lessened the value of the services which they have since rendered to the shareholders of the City of London Electric Light Company.

DISCUSSION.

The following is an abstract of the Discussion which followed on the reading of Major-General Webber's Paper. Speakers whose remarks are prefaced by an asterisk have returned their proofs revised.

A MEMBER asked whether the sum named for the conduits included the money spent on telephone tubes.

Another MEMBER referred to the marvellous speed with which the work had been carried out; an enormous amount of bitumen casing had been laid down, and engineers all knew the difficulty attendant on the laying of bitumen casing.

*Mr. GISBERT KAPP said that a large amount of information was given by Major-Gen. Webber as to the way in which he had designed the distributing plant. But what about the working of it? One illustration, showing a transformer sub-station, showed a two-storied building with the transformers in the lowest part. What about the water? Could transformers placed in this position be kept dry? Had Gen. Webber found a way of preventing the danger arising from this? Another point was that various systems of mains were being used, some in iron pipes, some in conduits; how had these behaved in practice? He did not think that sheet iron or steel, especially in such thin sheets as No. 22, could give much screening effect. He should expect it soon to be eaten away, and whatever shielding effect it had would thus be destroyed. Another point he should like to hear about was the connection with the customers. He understood that the low-pressure net works were not connected with each other; if this was correct he should like to know the reason for it. As to glow-lamp lighting, Gen. Webber seemed to have great doubt as to the practicability of lighting streets by glow lamps. Now it seemed to him (Mr. Kapp) that glow lamps were the right thing in many cases. Arc lamps cost £25 a year, and one wanted a good many of them to light a mile of street, so that their expense was enormous. In fact, it could only be used where the traffic was large; in all other places the expense was out of all proportion. What one wanted was a generally-distributed light For this glow lamps seemed the right thing. They had, moreover, the advantage of not requiring trimming.

*Mr. W. B. ESSON said that he would like to know something about the endurance of the distributing system, also the methods adopted for regulation at the sub-stations. Although there was a large number of statistics in the Paper, there was nothing much connected with the actual working of the system.

*Mr. ALEX. SIEMENS thought that there were many points in the Paper which deserved better treatment than had been accorded them by the meeting. He would like to call attention to one statement, which appeared to be entirely against a generally-accepted principle. Gen. Webber said that the consumption of coal was to be 7lb. per Board of Trade unit delivered at the terminals of the primary mains in the stations for arc lighting, and it was not to exceed 5lb. for alternating. This was directly contrary to the results which had been obtained. It would be very interesting to hear some remarks on this point. Another point about which he would like to hear something more was about telephone cables being protected against interference by sheathing. Twin telephone circuits should not want any protection. It was always invidious for him to say a word for lead-covered cables. All these wonderful conduits had various good qualities, such as bending, &c., but, nevertheless, he would have preferred to have laid lead-covered cables, which could be laid anywhere and anyhow, and could be threaded in, under or over, gas and water pipes, and tapped without any difficulty. He (Mr. Siemens) had not been without experience of city work, for, as Gen. Webber said, one of the three districts allotted in 1880 was given to his firm. One advantage of lead-covered cables was that there was no necessity to take precautions against gas explosions. Gen. Webber's statement that hollow-core cables were an advantage in the case of alternating currents was a fallacy. If alternating currents obeyed all the laws which were made for them they should keep to the outside of the cable. But the effect in practice was very slight, and the difficulty was overcome by making the cable slightly larger, which was better than making a hollow cable with a hemp core, which involved much more insulation and sheathing. For practical engineers money was the only thing which decided whether this or that system was to be adopted.

*Mr. J. B. BRAITHWAITE, jun., thought that Gen. Webber had indulged in uncalled for sneers against those who had the pluck to come forward and raise the capital at a critical moment. Gen. Webber had used the following words:—"As we all know, a very old way of commencing to raise capital has been brought out under a new name, namely, by the starting of a 'pioneer company,' which is one way of getting an instalment of capital together to make a beginning. Of course, there is no engineering justification for it, but the financial physician has prescribed it, and hence this first capital must be spent with a primary object of showing that something can and will be done. The future of the undertaking from the structural point of view may become quite a secondary consideration, and, indeed, may be ignored if it interferes with the parade with which it is intended to 'draw' the investing public. They—the public—have only themselves to thank if this sort of thing is necessary. Engineers and contractors have no real interest in its existence." He could not imagine a greater disservice than to tell electrical engineers that they had nothing to do with finance. What were the facts? At the time when it was necessary to commence work under the Provisional Orders for the Eastern aud Central Districts, the City had just experienced the greatest shock since Black Friday, 1866, by the collapse of the great house of Baring. Had money not been obtained, Parliamentary power would have lapsed, and this money had to be obtained at a time when it was commonly said that it was impossible to borrow 15s. on the security of a sovereign. Now it seemed to him that it was a matter of great interest to electrical engineers that men should have come forward and saved the provisional orders, and thus provided the means for enabling one of the largest electric lighting schemes in this country to be carried out. He, for one, entirely took exception to the sneers in the Paper, and would not further follow Gen. Webber's statements, many of which were—should he say—inaccurate.

*Mr. J. F. ALBRIGHT entirely endorsed Mr. Braithwaite's remarks. He had had some experience in trying to get schemes of the kind carried out and if they were to avoid all this sort of thing no large schemes could be carried out. He could not agree with Gen. Webber upon glow-lamp lighting, though they certainly wanted to be properly put up. He (Mr. Albright) should not like it to go forth from that Institution that the glow-lamp was inadequate to the requirements of street lighting. Glow lamps were undoubtedly useful, although, of course, they were not equal to arc lamps. He could not quite agree with Gen. Webber as to the advisability of adopting the Callender-Webber system. Experience had shown that it could not be relied upon as a "drawing in" system. He also joined issue with the President as to lead-covered cables. He believed the best of the systems they had before them for work in this kind o street lighting was wrought-iron tubes, into which thoroughly well insulated cables were drawn.

*Prof. SILVANUS P. THOMPSON said that General Webber was very anxious to do him justice in quoting his reports. The extracts made must not, however, be taken as giving the whole of his views. The reports were made to the City Company, and were not his property. He would not like it, therefore, to go out that those views were in any way his final ones; they were quoted apart from context. For instance, he was quoted as saying that the correct thing for electric lighting was vertical engines direct-coupled. Now, he gave that opinion with reference to a particular station and a particular district, and he was not to be understood to make the same recommendation where land could be had for almost nothing. Also his opinions about transformer sub-stations must be taken as bearing on the

Digitized by Google

particular case for which they were given. He would forbear to make any further remarks, because he had not had permission to make use of his reports. The suitability of glow lamps for street lighting largely depended on the way in which they were used. He should like to possess more facts about series glow lighting. Arc lighting was undoubtedly the right thing in many cases, but the use of glow lamps was usually restricted on account of the cost of parallel distribution. With respect to dioptric shades for arc lamps, they all knew Mr. Trotter's researches, which might in the future be found to possess more value than many engineers were aware of. At the present moment, in France, some engineers were carrying out Mr. Trotter's ideas to a further point. One thing certainly could be obtained in this way, namely, the abolition of the dark shadow immediately under the arc lamp. The very worst thing, too, was to place an arc lamp in a lantern on the top of an opaque pole, thus casting deep shadow at its base. With the proper use of the dioptric shade diffuser many objections against the use of arc lighting for interiors would be removed.

*Mr. R. E. B. CROMPTON: Gen. Webber had asked, in a footnote, the cost of laying bare copper strip in culverts on his (Mr. Crompton's) system compared with that of the high-pressure concentric main, running to the transformer sub-station, for which Gen. Webber gave the total cost of laying 1,200 yards, at £5,146, the annual upkeep being £367, whilst for low-pressure Gen. Webber had estimated a low-pressure feeder at more than £15,000. He had only received a copy of the Paper that morning, and had had no time to study it. but during the discussion he had worked out the cost of a low-pressure feeder to be about £4,400, and he would be perfectly prepared to carry out the work 100 times over at this price. Now, when they came to the maintenance, Gen. Webber gave for his high-pressure arrangement interest and principal at 4 per cent. ; £161 per annum depreciation and repairs ; 2½ per cent., £136 ; £70 for attendance ; and small stores, making a total of £367. Now he had had some experience in the upkeep of mains, and it was no longer a matter of guesswork or of estimated percentages to him, and he would assert that the total annual cost on his (Mr. Crompton's) system, would not be more than £150, as against £367. Either he was right or he was wrong, and in these figures lay the whole pith of the controversy between high and low-pressure mains. Only time and the accounts of the Companies would show who was right and who wrong. The Paper had not been sent out in time for him to take more than a superficial view of it, but so far as he could see the way in which the capital was raised was the most difficult part of the undertakings.

*Major-Gen. WEBBER, in reply, said that with regard to telephone or spare tubes, the figures given were extracted from the prospectus and published reports of the Company. As regards Mr. Kapp's remarks about the very slight screening effect of steel sheathing, he could only say that it was thought desirable that every precaution should be adopted. The reason that sound was heard in the test referred to was due to the fact that the telephone wires were parallel, not spirally twisted. There was no means of telling whether the sheathing was any good until it was down, and possibly money *had* been thrown away. Mr. Esson only made reference to the very points which he (Gen. Webber) had carefully guarded himself from going into. The information required could only come from those who had since had the experience. With regard to Mr. Siemens and the 5lb. and 7lb. coal consumption, these figures had not been adopted without due care and consideration. The 7lb. was an accepted figure for the Brush and Thomson-Houston arc lighters, and the contractors would not have been prepared to accept any other. As to the 5lb., he thought the figure a very safe one. As to the controversy between lead-covered cables and conduits, it was like the battle between the broad and narrow gauges. The essential object of conduits was to provide a means of drawing in wires for future requirements ; they did not wish to repeat the experience of the gas companies who first laid down small pipes, and then had to lay larger and larger ones. He did not pretend to quote Prof. S. P. Thompson literally, but merely wished to draw attention to such opinions of Prof. Thompson as justified the steps taken by him (Major-Gen. Webber). They were very much indebted to Mr. Crompton for the figures which had been drawn from him, and whether the £4,400 was sufficient to construct a conduit only occupying the same sectional area as that given by him as costing £15,000 was a question which practice alone could prove. The only note of discord was with regard to the steps taken by the financial world, and the remarks were all the more ungracious considering the quarter from which they had emanated. He had given the fullest credit to the Brush Company, and it was remarkable that the attack was made by their chairman.

PHYSICAL SOCIETY.

At a meeting of this Society on February 23, 1894, Prof. A. W. Rücker, M.A., F.R.S., President, in the chair, Mr. J. W. Kearton was elected a member of the Society.

A "Note on a New Electrical Theorem"

was read by Mr. T. H. BLAKESLEY, M.A., M.Inst.C.E. Two or more dispositions of electromotive forces in any network of conductors which produce at every part of the network the same currents are defined as *equivalent systems*. The following theorem is then stated and proved:—In any system of conductors possessing seats of electromotive force at any number of points, if any of these sources be moved along the various bars of the conducting system, and where a point of junction is encountered, each becoming a seat of the *same* electromotive force in *each* of the newly encountered bars, then the disposition at any moment is equivalent to that at any other moment, and, therefore, to the original disposition. Equivalent systems might also be defined as being such as produce equal expenditure of power in each part. From the above theorem the following propositions are deduced by the author:—1st. That if any closed surface contains a portion of a network then an electromotive force in any bar cutting the surface can be replaced by equal electromotive forces (in opposite directions as regards the surface) in all the other bars cutting the surface, without disturbing the current in any part of the network. 2nd. If two systems of electromotive forces be equivalent, one may be derived from the other.

Prof. C. V. BOYS, F.R.S., read a note

"On the Attachment of Quartz Fibres."

When torsion fibres are required to carry large weights approaching the breaking weight the ordinary method of attachment by shellac is not always satisfactory, for if the part of the fibre in the cement is twisted or bent the yielding of the sheliac causes uncertainty of zero. To avoid these troubles Prof. Boys has devised and perfected a method of soldering the fibres, full details of which are given in the Paper. After selecting a fibre of the right diameter and length, small weights are fixed on the ends by shellac. The end parts are then cleaned by dipping in strong nitric acid, washed, silvered, and electro-coppered. The weights are then cut off, and the coppered ends soldered to tags of tinned metal foil, chloride of zinc being used as a flux, and its capillarity serving to hold the ends to the tags whilst the latter are heated. The superfluous copper and silver are dissolved off by nitric acid, the tags and solder being protected by beeswax. After washing in boiling water the fibre is ready for use. Melted shellac is used for securing the tags to the torsion rod and suspended body. Several ingenious details of procedure to avoid capillary difficulties in the cleaning, plating, and washing processes are described in the Paper. If fibres are required to conduct electricity, they are silvered and washed after the tags have been soldered on. Such fibres the author considers essential for making connection with electrometer needles of the greatest delicacy, for liquid connections are fatal to stability. Methods of rendering fibres visible by smoking with arsenic or magnesium are mentioned in the Paper. At the meeting a perfectly circular hole $\frac{1}{5000}$ of an inch in diameter, made by soldering round a quartz fibre passing through a hole in a metal plate, and then drawing out the fibre, was exhibited under a microscope.

Mr. INWARDS asked if the shellac used to secure the tags was melted or dissolved.

Mr. BLAKESLEY inquired if silvering fibres did not destroy their perfect elasticity?

Dr. SUMPNER wished to know if any data as to the relative torsional rigidity of silvered and unsilvered fibres had been obtained, and if the electric resistance of silvered fibres had been determined?

Mr. WATSON said silvered fibres had been successfully used in electrometers. As regards their torsion, he had found it differ from day to day, and the resistance varied enormously.

In reply to a question, Prof. BOYS described the exact process of soldering the coppered fibre to the tags. As to the torsion of silvered fibres, he would not expect much increase as the film was very thin. He also thought the elasticity would not be destroyed, for silver and gold make very good torsion wires.

Mr. LITTLEWOOD read a note

"On a Method of Determining Refractive Indices."

This method was commended by the President, as being novel and very interesting, particularly well adapted for either homogeneous or heterogeneous liquids.

APPARATUS FOR THE STUDY OF HERTZIAN OSCILLATIONS.

Signor Augusto Righi, in the January number of the *Nuovo Cimento*, describes a modification of oscillation apparatus for lecture experiments for which he claims decided advantages over the earlier forms, and gives a preliminary report of some extraordinarily short waves which he has been able to investigate. In his apparatus an influence machine is substituted for the induction coil to excite the oscillator, the sparks in the latter cross between the terminals in an insulating liquid, and a Geissler tube is attached to the resonator. The terminals of a Holtz machine are connected with two brass rods, ending in knobs 30cm. in diameter. Between these knobs is introduced the oscillator. This consists of two brass rods ending in knobs on both sides. Two of these knobs approach each other to within 3 or 4mm., and are immersed in liquid vaseline. The other knobs are opposite those of the influence machine. The whole oscillator is about 72cm. long. Two copper discs 25·5cm. in diameter slide along the oscillator rods, and are usually placed 43cm. apart. The resonator consists of a circle of copper wire, 57cm. in diameter, part of which is formed by a

Digitized by Google

Geissler tube, 15cm. long. The wave length corresponding to this resonator is about 4·1m. With a Holtz machine, giving sparks 30. cm long, the tube glowed at a distance of 6m. from the oscillator sufficient to enable a large audience to perceive it distinctly, whereas the glow produced by an induction coil of 25cm. spark-length was extinguished at the distance of 1m.

Some good experiments could also be shown with a circular glass tube exhausted to 0.0086mm. A vertical sheet of zinc, 4 sq. m. in surface, was placed at a distance of 5m. from the oscillator, and the nodes and ventral segments between them manifested by the glowing of the rarefied gas. The glow was even more brilliant when the tube was employed to show the waves propagated along a wire.

Besides this lecture apparatus, Sgr. Righi has been able in the laboratory to investigate the shortest wave-lengths hitherto attained. In this case the oscillator was reduced to two brass spheres, and the resonator was made according to Hertz's original pattern. The shortest waves thus attained were 7cm. long. With these waves the experiments of Hertz and his successors were repeated, using reflectors, lenses, prisms and other apparatus of dimensions hardly exceeding those of the corresponding optical instruments. Besides the reflection by metals and refraction by prisms and cylindrical lenses, successful experiments were made upon the principal phenomena of diffraction, the interference of direct and reflected waves (like optical interference with a single mirror), and total reflection by a rectangular prism. The absorption of electric energy by metallic films and liquids was also studied. The greatest distance between oscillator and resonator was in many cases very considerable. It amounted to 1m. without, and 6m. with parabolic reflectors. With waves 20cm. long and two such reflectors, the greatest distance at which the sparks could be clearly observed was 25m.

THE ELECTRICAL EQUIPMENT OF THE LIVERPOOL OVERHEAD RAILWAY.*

BY T. PARKER, M.INST.C.E.

The plant was required to run a three-minute service on six miles of double track. In designing it, curves were drawn of the energy required at any point along the line of one loaded train with various accelerations, &c., to meet the time table service. From these curves the power required at the generating-station was calculated, and four dynamos were arranged for, yielding 475 amperes at 500 volts and 420 revolutions, or 1,200 e.h.p. in all. The dynamos were of the double-line type, rope-driven, with pulley between two bearings, so that the armature could be taken out without disturbing the ropes. The electrical efficiency of the dynamos was 97·77.

The switch-board, specially designed for safety and simplicity in working, was fully described. The main current passed to the line through a main magnetic cut-out, to break circuit at 3,000 to 4,000 amperes. The conductor was of steel, 4 sq. in. in section, supported on porcelain insulators. There were no feeders, and the return circuit was through the rails, which were bonded. At each station there was a cross-over road. The conductor was broken at these points, and the collector bridged across over the main rails without breaking circuit. It was necessary that the cars should be of the double-bogie type; it was, therefore, difficult to design motors to give the power necessary on standard bogie frames. Finally a type was adopted, as patented by Mr. Eickemeyer, which gave complete satisfaction. The motor occupied the front half of the bogie-truck. The weight of the magnets was taken off the axles by adjustable springs, and the magnets were kept in horizontal position by a lever arm fixed to the bogie-frame. Each car was complete with motor and switch-gear to run independently. Two cars were coupled together to form a train. Either the driving or trailing motor could be plugged out of circuit at will. A Westinghouse air-brake was attached to the car, also the usual hand-brake. The stations were lighted by 50-volt glow-lamps, run off accumulators fixed at the station, and charged from the main dynamos.

The efficiency of i.h.p. to e.h.p. on the line was taken with carefully calibrated instruments in the presence of the engineers. The tests extended over 3½ hours. The mean value of seven tests of No. 1 engine gave 88 per cent. i.h.p. to e.h.p. Curves were given of the power consumed during an experimental run of one train completing 5¼ miles in 24 minutes, 57 seconds, and 23 minutes, 47 seconds, with stops of 25 seconds at each station. The power required was 44·4 i.h.p. and 46 e.h.p. respectively. To compare this with actual running, curves were given from daily log sheets showing the effects on the generating station of the alteration to the train service. The advantage of a large number of trains in pulling down the maximum current per train was apparent. With seven trains this was twice, and with twelve trains only 1½ times the average current per train. With twelve trains running, the average demand for power continuously was 37 e.h.p. per train.

A comparison of coal used when the train service varied was given. During April and part of May seven trains were running at one time, and the coal used was 22·5lb. per train mile. From June to October there had been a 5-minute service from 9 a.m. to 5:30 p.m. The coal used per train mile for the four months of June, July, August and September, was 17·8lb., or making allowance for charging batteries, say 17lb. per train mile. The price of the Lancashire slack, which was used till the latter part of August, was 5s. 10d. per ton, but since that date, owing to the strike, the price for coal from various sources had varied up to 17s. 6d. per ton. Under the agreement the contractors had to run the service of trains for 3½d. per train mile, on a full service of 2,400 miles per day, but as only 5¼ miles of line were open they received 4d. per train mile, and for current to charge lighting batteries 7d. per Board of Trade unit. Figures were given of the actual working costs for July, August, and September, 1893, which were 3·44, 3·70, and 4·07 pence per mile respectively. The increased cost of running for August and September was fully accounted for in the item of coal, and as the railway company had not employed as frequent a service as at first anticipated (this being only 1,350 miles per day) the figures showed most favourably, it being evident that, with coal at an average value, the line could be run at a cost well within that guaranteed by the contractors.

* Abstract of a Paper read before the Institution of Civil Engineers, Tuesday, February 27th.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, March 2nd.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting at 25, Gt. George-street. The following Paper will be read: "Efficiency and Economy of Elevators," by Herbert W. Umney Stud.Inst.C.E.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting at 28, Victoria-street. The following Paper will be read: "Lightning," by E. H. Bowyer.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Theory of the Cochlea and Inner Ear," by Prof. John G. McKendrick, M.D.

SATURDAY, March 3rd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture on "Light," with special reference to the Optical Discoveries of Newton, by the Rt. Hon. Lord Rayleigh, F.R.S.

MONDAY, March 5th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

TUESDAY, March 6th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Monthly Ballot for Members. The following Papers will be further discussed: (1) "The Liverpool Overhead Railway," by J. H. Greathead and Francis Fox, M.M.Inst.C.E.; (2) "The Electrical Equipment of the Liverpool Overhead Railway," by Thomas Parker, M.Inst.C.E.

WEDNESDAY, March 7th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. The following Paper will be read: "Refrigerating Apparatus," by Prof. Carl Linde, of Munich.

THURSDAY, March 8th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting. The following Paper will be read: "A Note on Parallel Working through Long Lines," by W. M. Mordey, Member.

FRIDAY, March 9th.

PHYSICAL SOCIETY.

8 p.m. The following Paper will be read: "Calculating Machines and especially a new Harmonic Analyser," by Prof. O. Henrici, F.R.S,

JUNIOR ENGINEERING SOCIETY.

8 p.m. Ordinary Meeting at the Westminster Palace Hotel, Victoria-street. The following Paper will be read: "The Design, Construction, and Working of Boilers for Locomotive Engines," by Mr. G. Frank Burtt.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Making of a Modern Fleet," by William H. White, C.B., F.R.S.

SATURDAY, March 10th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture on "Light," with special reference to the Optical Discoveries of Newton, by the Rt. Hon. Lord Rayleigh, F.R.S.

THE BOARD OF TRADE AND THE ELECTRIC TRACTION REGULATIONS.

The result of the important conference over which Sir COURTENAY BOYLE presided last week will be announced in the course of the present month by the issue of regulations for the use of electricity by tramway and railway companies. From the contentious atmosphere of Mr. Justice KEKEWICH'S Court, from the ill-feeling encouraged by direct conflict of commercial interests, and provoked by acrid cross-examination, the change of venue to the august but less formal Committee of Lords and Commons was some relief; but even here the battle of telephones *versus* traction was carried on, chiefly by the harangues of Parliamentary barristers, who could always say or suggest unpleasant things, "by instruction." But when the scene changed, for the third time, to the quiet gathering round a table at Richmond-terrace, all ill-feeling seemed to have disappeared. Angry threats, the quibbling of experts, and tall talk about disagreeing with the whole of the draft regulations *en bloc*, were impossible at such a meeting, and with such a Chairman.

The drafting of these regulations is a rather remarkable piece of work. The Joint Committee recommended that such regulations should be made, and their Report was ordered to be printed on July 13, 1893. Four months later, the draft regulations were issued; three months have been allowed for their consideration by the various parties interested, and

Digitized by Google

within a few weeks of the recent conference, the final regulations will be scheduled to the various Bills passed last session. The regulations cover quite new ground; they are not modelled on existing railway work, nor on electric light supply. It may be confidently said that they give general satisfaction to all those who have carefully studied them. Not less remarkable than the regulations themselves, is the procedure of the important Government Department which was charged with the work. There is certainly no other Government Department in this country, and probably in no other land, which would issue tentatively in draft form, a set of altogether new regulations—to all intents and purposes, laws—and invite, listen to, and amicably discuss them with the public. No formal deputation, no frigid official speech, not a sign even of red tape in any form, no parties hurt because not invited, none injured because unheard. The Board of Trade is a department of which Englishmen may be justly proud, and few there are who have a clear idea of its manifold duties. The Electrical Department, in some respects an offshoot of the Railway Department, is perhaps most remarkable for the disproportion between the public importance of its work and the ridiculously small staff for executing it. For the drafting of these regulations we estimate that rather more than three-quarters of one officer was available. We reckon one-seventh of Sir COURTENAY BOYLE's time, one-sixth of that of Mr. HOPWOOD, one-fifth of Sir THOMAS BLOMEFIELD, who was for a few years engaged almost exclusively with electric lighting, but who is now, according to "Whitaker's Almanac," one of the "principals," and, we understand, chiefly concerned with the Railway Department. Major CARDEW, the "electric adviser," is, of course, busily engaged in scientific work in the Standardising Laboratory and elsewhere, and we have estimated one-third of his time for the work we are discussing. The whole adds up to a very vulgar fraction, but not a vestige of inefficiency is discernible in the work. It was promised, if we remember rightly, by the then Government, in connection with the Electric Lighting Act of 1882, that the care of electric lighting by the Board of Trade should cost the Treasury nothing—it would be self-supporting. How has this promise been kept? A fee of £50 has to be paid upon each Provisional Order; 280 Orders have been granted, and £14,000 have accordingly been paid to the Board of Trade. But one of the remarkable customs of our Government department is, that all such fees go straight to the Treasury; they merely pass through the books of the Department that really earns it. One source of revenue after another is created and developed, the money is not earmarked, it all goes into the general revenue of the country, and as soon as it has grown into a sum worth grumbling about, it has become a sum which the Chancellor of the Exchequer finds to be worth sticking to. Nothing is capitalised, even on paper; there is no reason for this, only a custom. The Patent Office, another department of the Board of Trade, has for many years earned large sums, and only quite recently has it been permitted to spend anything on much-needed buildings for new offices and library. The Electrical Department needs developing. Busy as are its officers, every one who has to go to or to correspond with any of them is ready to acknowledge the courtesy, care, and thoroughness which distinguishes this from many other Government Departments. Up to the present the Board of Trade has managed to keep pace in the matter of electric lighting with the work devolving upon it. It is true that at first there was great delay in auditing the accounts of the electric supply companies, but now they are audited before they are published. Although the number of new Orders in each year has diminished rapidly since 1890, the work of the Electrical Department must increase as steadily as electrical supply is increasing, and the recommendations of the Joint Committee on "Electric Powers Protective Clauses" opens an entirely new branch, not contemplated under the Electric Lighting Acts. As traction some of this work will no doubt fall to the Railway Department, but the majority of it is purely electrical, and all of it is additional and new.

When it was decided that a Parliamentary Committee was to discuss the question of the regulation of electric traction, those interested in heavy electrical engineering were filled with a mixture of anxiety and joy. When the Committee formulated its recommendation they were still filled with the same things, but in different proportions: more joy and less anxiety. Joy because they had good hope of electric traction being made commercially possible; anxiety because regulations were to be drawn up, and they did not quite know what those regulations might demand. The most curious part of the affair is that it was originally war to the knife between the telephone and traction interest; but the gas and water companies gave watching briefs to counsel, who watched, and were astounded to find that not only were the telephone people sending messages along their pipes without even asking permission, but the traction companies were slowly but surely converting their tubes into hydrated ferric oxide. As the telephone interest did not want clauses preventing the gas and water companies from sending fluids through the pipes in case they might interfere with their use as telephone conductors, the telephone and ponderable fluid companies were not inimical; but traction found it had stirred up a hornets' nest. The telephone subsided into the background, and the question of real importance was how to protect pipes. This was, of course, a matter of grave importance. The Committee, with the caution begotten of wisdom, left the matter to the Board of Trade, knowing that if care and hard work could frame suitable regulations, the experts advising the Board would succeed in doing so. Indeed if one thing be more remarkable than another in connection with the recent industrial development of electricity it is perhaps the perfect unanimity with which Lords and Commons, traction men and telephone men, the public and the expert are ready to leave the solution of all and every knotty problem to the Board of Trade. On the Board of Trade! let us leave the interpretation of our laws, the making of our rules, our lighting, traction power, our lives, our sins lay on the Board of Trade.

At one time the question was, Which side will win? But no such issue appeared to be in view at the conference. The struggle was really at an end when the Report of the Joint Committee was issued. The traction members appeared to concern themselves about details, while the National Telephone Company strove rather for principles. The object of the conference was to settle details, for the Joint Committee had decided principles, and anything more that could be said about them was to interpret or to apply them. One danger threatened the traction interests. The draft regulations had been carefully considered by a committee of the whole council of the Institution of Electrical Engineers, by a special committee of the Electrical Trade Section of the London Chamber of Commerce, by certain experts in connection with Imperial Tramways Company, and by Dr. FLEMING on behalf of the Association of Municipal Corporations. More than once the views of these parties differed, more than once an amendment proposed by one was unhesitatingly opposed by the representatives of another, nor on purely technical matters did they always agree. But their common opponents took no advantage of this weakness, they were merely amused. One result

Digitized by Google

of this lack of unanimity on the part of the traction members was to disincline the representatives of gas, water, and railway interests to place much reliance on the technical opinions expressed by the electrical engineers and electricians. On Regulation No. 5, the gas companies were greatly alarmed at the idea of deliberate connections between the negative conductor of a tramway and their pipes "which contain an explosive mixture," and implored that no connection of any sort might be made. Assertions that this was the safeguard against corrosion were unheeded until Sir Courtenay Boyle himself assured them that this was their only protection.

THE MAGNETIC TESTING OF IRON.

It is some years since the Institution of Electrical Engineers has devoted a sitting to the discussion of a purely magnetic subject, and Mr. Kapp is to be congratulated on having endeavoured, by means of a somewhat too brief a Paper, to elicit from several firms of dynamo and transformer makers their respective methods of determining permeability of, and hysteresis loss in, the various qualities of iron used in their machinery. It must be frankly confessed that one of the most unsatisfactory features in connection with modern dynamo design is the lack of any simple and rapid workshop method of determining hysteresis loss and permeability, and we hardly think that Mr. Kapp has satisfactorily solved the problem. The objections to his method, in common with many others, may be summed up in one word—joints. In every method with which we are acquainted of determining permeability by means of a sample forming a joint with a soft iron return, the resistance of the joint is indeterminate and is a cause of magnetic leakage between the sample bar and the return; that is to say, the length of the sample bar under test is not a constant quantity, and varies with its permeability and with the resistance of the air gap. This objection, of course, applies equally to the instrument devised by Mr. Kapp for testing transformer iron. But putting aside for the moment the question of method, we are glad to see stress laid upon this last remaining source of uncertainty in dynamo design, and since Mr. Kapp recognises the importance of eliminating it, it is curious to note that his Paper contains no allusion to the question of the armature in dynamo machines; the armature is the soul of the dynamo: one can imagine a dynamo having an armature and no field-magnets, but a dynamo having only fields would not be a dynamo at all. Why, then, this neglect of the armature? The answer is, we are afraid, obvious. Mr. Kapp's methods do not directly admit of the determination of the permeability of the armature on which depends to a large extent the characteristic of the machine, and no method of iron testing can be considered of any great value unless it allows of this determination. The only clue to this, in Mr. Kapp's instrument, is the magnetising current, and the pressure on the terminals of his magnetising coil, and these are only available if the shape of the current and electromotive-force waves is known, for the measuring instruments only record effective and not maximum values. Not only is this difficulty encountered, but the losses in the armature due to hysteresis are often of importance, and the quality of the iron used in the armatures of large machines should always be the subject of investigation. Mr. Kapp gives us no clue as to the method which he would adopt in this case; would he run alternators at a frequency of between ten and twenty periods per second, or does he derive his estimate of hysteresis by elimination of eddy-current losses from observations at varying frequency? Some years ago, in our columns, Mr. Evershed gave a formula for the calculation of eddy-current losses in a lamina of given thickness for given induction, and it is possible that Mr. Kapp uses a similar method of calculation, but we do not know whether anyone has actually tried an experiment to determine whether or no the formula is in accordance with the facts. We believe Mr. Evershed assumes that the lamina is very thin, whereas armature plates are often of a reasonable thickness, since, owing to the low frequency, eddy-current losses are small in comparison with those due to hysteresis. There is thus reason to doubt whether any calculation of eddy-current losses would be satisfactory. But not only is there this source of uncertainty—even supposing that the test were carried out by means of an alternator running at a frequency of about fifteen periods per second, it is by no means certain that the result would be in accordance with that which actually occurs in the dynamo when running. We believe it was Mr. Swinburne who made the remark that if the Ewing theory of magnetism is correct, the hysteresis loss should be less, other things being the same, in a dynamo armature than in an alternator; for the loss by hysteresis must be due to the oscillation of the molecular magnets about their mean position on the sudden breaking up of the molecular chains, and the formation of new ones; and this would not occur in an armature where the molecule are rigidly held and gradually turned round and round. This point can apparently only be settled by direct measurement in an armature, or by subjecting the iron under test to a magnetising force rotating in direction, and not varying in strength.

In fact, the whole question of the workshop testing of iron is in a most unsatisfactory state, and none of the methods employed by the various firms represented on Thursday last appears to be quite perfect. The amount of skill and time required to turn Mr. Kapp's test bars quite counterbalances, if it does not more than counterbalance, the fact that his experimenters need comparatively little skill. The amount of skill required to read any instrument whatever in a proper manner, precludes the use of a totally untrained man for the work; and the increase of skill required to read a ballistic galvanometer deflection is not very great. Too much was, in fact, made of this point. In these days, when the market is flooded with students of technical colleges, all more or less capable of reading a ballistic galvanometer, and whose services may be secured for a most modest honorarium, it is idle to talk of the skill required to take ballistic galvanometer deflections. The inception of the methods, the design of the instruments, these may require skill and experience of an expensive kind; but the use of this machinery is not confined to its designers, and it should be an easy matter to the average "third-year student."

There are one or two methods to which allusion was not made last Thursday, the chief omission being, doubtless, Prof. Ewing's ingenious and beautiful machine, which is, perhaps, too much of a laboratory instrument for workshop tests, and the complete ring methods used by Prof. Ewing, Messrs. Evershed and Vignoles, and others. There is little doubt in our minds that the wattmeter method, simple and direct as it undoubtedly is, must ultimately give way to some method of determination of what one speaker ingeniously termed the "hysteresis lozenge," for the latter gives the experimenter complete information, whereas the former only gives him the hysteresis loss, mixed up with that due to eddy currents, leaving the permeability curve unknown, and even the permeability at the particular induction a matter of some uncertainty; and it is curious to note in this connection with what singular unanimity the opponents of the alternate-current

Digitized by Google

wattmeter have hauled down their flag. Not so many years ago Mr. Swinburne's was as the voice of one crying in the wilderness, Why not use wattmeters to measure alternate-current power? and the idea was scouted; but now no one thinks of measuring it in any other way. *Tempora mutantur, et nos mutamur in illis.*

ELECTRIC TRACTION REGULATIONS.—CONFERENCE AT THE BOARD OF TRADE.

On Wednesday 21st ult., a conference was opened at the Board of Trade offices, 8, Richmond-terrace, between the Board of Trade and representatives of the interests concerned, to discuss the electric regulations, (see *The Electrician* November 24th, 1893, p. 46), which have been drafted by the Board of Trade. Sir Courtenay Boyle presided, and was accompanied by Mr. F. J. S. Hopwood, Major Cardew, and Sir T. W. P. Blomefield, Bart. Among those present were Mr. A. Siemens, Mr. R. E. Crompton, Major-Gen. C. E. Webber, C.B., and Mr. W. M. Mordey, for the Institution of Electrical Engineers; Mr. Gaine, Mr. Sinclair, and Mr. Winterbotham, for the National Telephone Company; Mr. J. Clifton Robinson, for the Imperial Tramways Company; Mr. W. J. Carruthers Wain, Mr. A. Wilmslow, Mr. A. P. Smith, Mr. J. Waugh, Mr. J. Hesketh, Mr. T. Hewson, and Mr. J. G. B. Elliot, for the Tramways Institute; Mr. J. Kincaid, Mr. Manville, and Mr. A. Dickenson, for the Bristol, Birmingham, Central and South Staffordshire Tramways; Mr. R. P. Sellon, Mr. E. Garcke, Mr. J. W. Winslow, Mr. S. Sellon, and Mr. H. F. Kite, for the Traction Committee of the London Chamber of Commerce; and representatives of the Gas Light and Coke Company, the Associated Metropolitan Water Companies, the Association of Railway Companies, and the Association of Municipal Corporations.

Sir COURTENAY BOYLE, in opening the proceedings, said they had met to discuss the regulations of the Board of Trade under clauses which were in certain Bills, and which probably would be inserted in all Bills as model clauses, in consequence of the recommendation of the Joint Committee of last year. The regulations would therefore have general application, and they were discussing practically what he supposed would be instances of traction by continuous current. There were matters of great controversy involved, and most important interests were affected, and it was the sole object of the Board of Trade to arrive at the fairest possible solution of these serious difficulties that could be reached. The first amendment (see *The Electrician* February 23rd, p. 458), was an addition to the definitions proposed by the Institution of Electrical Engineers, which read:—"The expression 'line' or 'lines' means an insulated conductor or conductors used for transmitting energy from the generator or generators to the trolley wire or other conductor from which the current is taken to the motor or motors by a rubbing contact. The expression 'return' or 'returns' means the conductor or conductors uninsulated or otherwise, used for completing the circuit or circuits between the motor or motors and the generator or generators."

Major CARDEW said there had been a misconception with regard to the meaning of "insulated throughout its length." It appeared that a great many gentlemen thought this must mean insulated with india-rubber or some material covering, and that a wire suspended in air on insulators did not come within the meaning of the expression. Undoubtedly the Board of Trade considered that it did, but he thought it might be made more clear in the regulation.

Sir COURTENAY BOYLE said he would consider the proposal as a drafting amendment. The next point was that raised by the London Chamber of Commerce, who understood that the definition of current was not intended to apply to telegraphic, telephonic, and railway signalling currents. The answer to that was that the word "current" all through the regulations applied to traction current only. The Chamber of Commerce also proposed that, in the first regulation, the word "steady" in the expression "a steady continuous current" produced by a dynamo used as a generator should be defined in the definitions. Major Cardew suggested that instead of the word "steady" should be substituted "without appreciable pulsation."

Mr. SIEMENS did not see any objection to the word, because everybody knew that there were fluctuations, and that it was simply "steady" to distinguish it from the alternating current.

Major CARDEW said the intention was to go rather beyond that, and to distinguish it from such a current as that of the Brush arc lighting machine, a so-called continuous current which had very perceptible pulsation, and would very greatly affect telephones.

Mr. WINTERBOTHAM and Mr. SIEMENS thought Major Cardew's suggestion was a good one.

Sir COURTENAY BOYLE said they would put in "without appreciable pulsation" either in the regulation itself or by way of definition.

Mr. S. SELLON said they suggested that in the second regulation regarding the insulation of conductors transmitting energy from the generator to the motors the words "insulated from earth" should be substituted for "insulated." They must have bare wire in the case of an overhead conductor.

Sir COURTENAY BOYLE said they would draft some words to clear that difficulty.

Mr. MONIER WILLIAMS, on behalf of the Gaslight and Coke Company, said the returns should be entirely insulated in the metropolis "excepting places where the Board of Trade should, after a full investigation of the special circumstances, see fit to sanction the use of such returns."

Sir COURTENAY BOYLE said he would take that objection at the end. The next objection was from the Imperial Tramways Company (Limited) as to the meaning of the expression "insulated throughout its length."

Mr. CLIFTON ROBINSON said that Major Cardew's suggestion would meet their difficulty.

On the third Regulation, that where any rails on which cars run, or any conductors laid between such rails, form any part of a return, such part may be uninsulated, while all other returns or parts of a return shall be insulated, the Institution of Electrical Engineers suggested the wording, "between or contiguous to such rails."

Sir COURTENAY BOYLE asked if they would mind "within three feet of."

Mr. SIEMENS said that would do very well.

Mr. WINTERBOTHAM asked why it should not be 18 inches.

Sir COURTENAY BOYLE said he thought they would insert "or within 3ft. of" the rails. The Institution of Electrical Engineers also proposed the insertion of the words, "but the supports of all overhead wires, whether line or return, should be electrically connected to the return circuit."

Mr. SIEMENS said the object was to get all leakage currents into the metallic return with the greatest possible certainty. If the overhead line, which ought to be insulated, leaked, it would go into the metallic supports, and from the supports it would go into the metallic return.

Major CARDEW thought it was a good suggestion, but hardly the right wording. He thought they could deal with it by a fresh regulation.

Sir COURTENAY BOYLE: We will insert it as a new regulation.

Mr. S. SELLON, on behalf of the Chamber of Commerce, and Mr. CARRUTHERS WAIN, on behalf of the Tramways, objected.

Mr. DICKINSON, on behalf of the Traction interest, objected to it because it would be an unnecessary cost, and would not do what it claimed to do. It would cause a breaking up of the streets in every 50 yards, and would not do any good at all.

Mr. LANGDON said the resistance between the rails and the support of the trolley wire would be very light and slight indeed, and indeed there might be no resistance at all, it might be totally unappreciable, much less than that which the earth return would give.

Mr. DICKINSON pointed out that each support for the trolley wire was in itself an earth plate; and if there was leakage from the trolley wire it went back through the earth. All of these supports were huge earth plates. At the bottom—in South Staffordshire construction at least—they had a plate some two or three feet square.

Mr. S. SELLON said their poles were exceedingly well insulated, and if they were properly laid in concrete they were absolutely insulated in earth, and the failure of one single insulator on the whole line would absolutely destroy the whole resistance.

Sir COURTENAY BOYLE: I will consider the proposal and the objections. I think it better to be perfectly frank, and to say, Mr. Sellon, that I am rather against you at this moment on this point; but I will further consider it.

The Institution of Electrical Engineers next suggested the qualification of the word "insulated" by "unless of such sectional area as shall satisfy the Board of Trade."

Mr. SIEMENS said that was to carry out one of the regulations of the Joint Committee, who said that the best protection for all pipes against electrolytic action was to have the return conductor of a metallic section, which reduced the resistance, and so made the current principally or almost entirely go back through the metal. Under such circumstances the Committee said it should not be imposed upon the traction companies to have insulated returns.

Major CARDEW said there was certainly some reason in allowing the rails to be used as a return for facility of traction work, but he thought that that did not apply to other conductors where no extra facility was given by having them uninsulated, and where there was only possibly a small saving of expense.

Sir COURTENAY BOYLE said it was not a very convenient way of legislating to say that the Board of Trade had got to approve of the sectional area in particular cases; it had always led to disturbance.

Mr. SIEMENS said the real protection against electrolytic action was the low resistance of the return.

Mr. CROMPTON thought Major Cardew was somewhat in error when he thought that it would add very slightly to the expense of insulating the feeder part of the return. The cost of insulating multiplied the cost of the copper by at least four times, and if that was so they could afford to give four times the sectional area of copper, and so reduce the difference of potential on that portion of the return to one fourth. The point was one of extreme importance. He thought himself that a partially uninsulated return might be found impracticable, that it would localise corrosion on the point where the insulated portion joined the uninsulated portion, and greatly increase the cost of repairs to the tramways company. Further than that, it would defeat the object that the Board of Trade had in view, which was the preventing of stray currents through the earth.

Sir COURTENAY BOYLE said they would further discuss the position of non-insulation on Regulation No. 6, by treating it as a question of potential. On Regulation No. 4, which provides that when any uninsulated conductor laid between the rails forms any part of a return it shall be electrically connected to the rails at distances apart not exceeding 100ft., by means of copper strips having a sectional area of at least one-sixteenth of a square inch, or by other means of equal conductivity.

Mr. WINTERBOTHAM, for the Telephone Company, said they suggested that the same rule should apply to uninsulated returns as was embodied in Regulation 13, which provided that where there was an insulated return, whether it was overhead or underground, it should be

Digitized by Google

within a limited distance of the outgoing conductor—3ft. when they were overhead, and 18in. when they were underground. They suggested that where the outgoing conductor was overhead the copper wire which now supplements the rails should be carried overhead too, and that it should be connected with the rails at the posts when it was underground. They believed that would practically remove the main objection to the disturbance of telegraph and telephone lines. They proposed to strike out the word "insulated" in Regulation 13.

Sir COURTENAY BOYLE said he would not decide the point on that day.

Mr. HOLROYD SMITH suggested that instead of laying the insulated feeder or supply cables underground, or supporting them on the poles, if they laid those insulated cables between the rails parallel with the uninsulated return copper that supplemented the return of the rails, and coupled that up from the insulated cable between the rails to the trolley wire above, it would accomplish electrically precisely what the Telephone Company wanted.

On Regulation No. 5, dealing with earth connections in the case of returns uninsulated in any part,

Mr. SIEMENS said they proposed that the paragraph providing for a non-conducting screen in some cases should be struck out.

Mr. MONIER WILLIAMS, on behalf of the Gas Company, suggested that no connection should be made with any water pipe if there was a gas pipe anywhere near it without the consent of the Gas Company to whom the pipe belonged.

Sir FREDERICK BRAMWELL suggested that the connection to a water main should only be made with the consent of "the undertakers supplying the water thereof."

Major CARDEW suggested after the first proviso to put in "and provided that where, from the nature of the soil or for other reasons, the Company can show to the satisfaction of an inspecting officer of the Board of Trade that the earth connections herein specified cannot be constructed and maintained without undue expense, the provisions of this regulation shall not apply."

Mr. S. SELLON believed that at Leeds, where a line had been running for two years connecting the negative terminal to the pipes, there was no question of electrolysis to be found anywhere.

Mr. SIEMENS said it was brought out before the Committee very clearly that if the water main was made the negative pole it could not possibly be electrolysed, and also if the return was made a metallic return of ample section the pipes were protected.

Mr. MONIER WILLIAMS said the penalty was not sufficient to protect the gas companies. They ought to be protected from injury to life and property.

Sir COURTENAY BOYLE said he could not legislate in a regulation.

Mr. HOLROYD SMITH suggested that it would serve the purpose of the objectors better if they asked for a regulation that where their pipes came within a given distance, say 6ft., of the return of the tramway line, they should compel the Tramway Company to connect all their pipes, which would save all danger from electrolysis whatever.

Mr. CROMPTON thought it was held by every engineer that the only protection was to connect the negative pole with the dynamo.

Sir COURTENAY BOYLE said in place of the paragraph as to the provision of the non-conducting screen, Major Cardew proposed to substitute "No portion of either earth connection shall be placed within 6ft. of any pipe except a main for water supply of not less than 3in. internal diameter, which is metallically connected to the earth connection with the consent of the owner of the main." The paragraph in regard to a connection with a water main stands with the alteration suggested by Sir Frederick Bramwell, and that reservation of the alteration suggested by the Gas Company, upon which he would take further advice.

Sir COURTENAY BOYLE: The next point is raised by the Associated Railway Companies, who say that a uniform system of joining up the generators be observed, whether the return wire be insulated or not, the object of this being to enable the block instruments to be joined up in such a manner that the traction current shall produce the "Train on line" signal, and not the "Line clear" signal.

Major CARDEW said that wherever there was an uninsulated return it was already provided by regulations that it was to be connected to the negative.

On a point raised by Sir HENRY OAKLEY as to the possible damage resulting from the reversal of an electric current on a block signal of a railway, and the danger thereby ensuing,

Major-General WEBBER thought it would be a great pity if it left that room that the electrical doctors were unable to prevent the danger that Sir Henry Oakley apprehended absolutely and entirely. The protection of the block signals of the railway companies entirely lay in the hands of the railway companies.

On Regulation No. 6, dealing with the provisions imposed upon a company in the construction and maintenance of a tramway when the return is partly or entirely uninsulated, the question raised in Regulation No. 3 was settled by substituting for the words, "satisfy the Board of Trade," the words "reduce the difference of potential as described in 6 (c)."

Mr. SIEMENS said they proposed in the paragraph (i.) "That the current passing from the earth connections to the generator shall not at any time exceed 10 amperes," to substitute for "10 amperes" "2 amperes per mile of single track without the consent of the Board of Trade." If the distance between two points, which were connected by tramways, was five miles, and it was a double track, then they should be allowed ten times 2 amperes —20 amperes leakage.

Mr. S. SELLON: As far as we are concerned we suggest not limiting it, but giving a percentage of the output—5 per cent.

Sir COURTENAY BOYLE: Surely it is better to have the relation to the length of the line.

Mr. SIEMENS suggested that perhaps it was a better way to make it as a percentage of the output because that took into calculation also the frequency of the service—not only the mileage, but the frequency. He would beg, therefore, to withdraw this amendment in favour of that proposed by the London Chamber of Commerce—"It is suggested that the current permissible should be 3 per cent. of the total output of the station."

Mr. WINTERBOTHAM objected to the withdrawal of the amendment.

Mr. MANVILLE said the fact that affected them most was the length of bare return conductor that went to earth. As to the leakage varying with the number of cars that had to be run on it, the leakage was not likely to be greater with a greater number of cars than with a small number, but the length of the return conductor that is exposed to the earth was that which affected them distinctly. He thought a given leakage per mile of single track was distinctly the one that would serve the electric traction interest best of all.

Mr. DICKENSON entirely disagreed with the conclusion arrived at.

Dr. FLEMING asked that this should not be defined simply as an absolute current, but that it should be a time average. The real thing that this regulation was intended to protect was the total leakage from the line as affecting any damage to pipes, and that total leakage did not depend upon the strength of the return at any one instant, it depended upon the total quantity that was passed. Therefore, he had asked for a modification of five amperes per mile of tramway, and that it should be, not the actual strength of current at any one time, but the average as measured by an ampere-hour meter—that the total leakage should have some relation in the first place to the length of the line, and that with every mile of length of line those five amperes should be added as measured by the ampere-hour meter.

Sir COURTENAY BOYLE asked which was the best gauge—length of the line or amount of the output.

Mr. HOLROYD SMITH said length of line was the best because they had the line, and it had an uninsulated wire supported upon insulators: the number of those insulators were the fact that determined the current which should flow. The longer the line the greater the opportunities of escaping.

Major CARDEW: Some of it might come from the line, but the idea is that the current is leaking out from the uninsulated return.

Mr. HOLROYD SMITH: That is also governed largely by the length of the line, because the longer the line in the usual custom the more the cars that would be working upon it. He would suggest that the clause be put alternatively—either so much per mile or the percentage.

Mr. CROMPTON suggested that it should be struck out altogether.

Mr. SIEMENS said the leakage current depended only on the difference of potential between the uninsulated return from the distant parts and the earth plates. The potential would not vary, because they must make the section of their return greater if they had a greater traffic.

Sir COURTENAY BOYLE said he would take both the mileage factor and the output factor; it must not exceed that which was least in either case. With regard to the quantum of the mileage and the quantum of the output, he thought "two amperes per mile of single track" would do, and 5 per cent. of the output.

Mr. WINTERBOTHAM: The minimums in each case, of course.

Sir COURTENAY BOYLE: Whichever is lowest.

Mr. LANGDON: Is there any limitation to the amount of output from the generating station?

Sir COURTENAY BOYLE: There is no limitation of the current.

The next point was the proposal of the Institution of Electrical Engineers to strike out the paragraph relating to the direction of the current, and substitute "That if at any time and at any place a test be made by connecting a voltmeter to the uninsulated return, and to any pipe which the current could reach without traversing more than 6ft. of earth, the difference of potential arising from the working of the tramway between them should not be greater than four volts if the return is positive to the pipe, or greater than one volt if the pipe is positive to the return."

Mr. SIEMENS said this was suggested to bring in the difference of potential in volts instead of reversing the current by Leclanché cells.

Major CARDEW thought, for the purposes of the regulations, it was preferable to adhere to the Leclanché cells in place of a special voltmeter such as was indicated by the Institution of Electrical Engineers. They would observe that it was an opposing electromotive force, and therefore there would be no question of the polarisation of the cells. They had only got the opposition of the electromotive force to overcome; and it was to the tramway engineers' interest to see that the Leclanché cells were in good order. There was no question of the resistance of the cells; they had only got the electromotive force. As far as regarded satisfying the water companies he must say he felt that in provincial towns they could get sufficiently good advice to tell them whether the test was *bonâ fide* if made with Leclanché cells, but it would be very difficult for them to feel certain as regarded the indications of a voltmeter. After a short adjournment,

Sir COURTENAY BOYLE said they would adopt the amendment of the London Chamber of Commerce in regard to reversing the normal direction of the current by interposing a battery of three Leclanché cells, or in the reverse direction by one cell, subject to one or two verbal alterations.

On Regulation No. 7, in regard to the testing of the electrical resistance of the return, the proposal of the London Chamber of Commerce that for this regulation should be substituted, "when the return is partly or entirely uninsulated, a record shall be kept by the company of the extreme difference of potential reached during the working of the tramway measured between the most distant part of the system and the nearest home point of the uninsulated portion of the system, and if this record shows that at any time the recorded difference of potential exceeds 15 per cent. above the value, the company shall take immediate steps to reduce the difference to the required value" was adopted, with the substitution of "seven volts" for "15 per cent."

Digitized by Google

On the proposal of the Institution of Electrical Engineers to redraft Regulations 9, 10 and 11, in regard to the testing of insulation, as one regulation.

Mr. WINTERBOTHAM said they were going to test the cables which might have a very high insulation; but by this proposal they were going to leave out all the joint-boxes, test-boxes, &c., and, therefore, the test would be of no value.

Mr. CROMPTON said the high test of 10 megohms was solely for the cables. The real test for the insulation of the line was the leakage test.

Regulation 9 was passed provisionally.

After some discussion on Regulation 10,

Sir COURTENAY BOYLE said the words, with the suggestions which had been made, ran thus:—"The insulation of the line and of the insulated portion of the return, when both are coupled up ready for work, shall be such that the leakage current shall not exceed one-hundredth of an ampere per mile of tramway. The leakage current shall be ascertained daily before or after the hours of running when the line is fully charged, and if at any time it exceeds one-tenth of an ampere per mile, the leak shall be localised and removed as soon as practicable. The running of the car shall be stopped until after the leakage has been localised and removed. Provided always that where both line and return are placed within a conduit this regulation shall not apply."

Mr. DICKENSON thought it would be impossible to work a tramway commercially under such conditions.

Sir COURTENAY BOYLE: I will give you 24 hours—"The running of the car shall be stopped unless the leak has been removed within 24 hours."

On Regulation 13, as to the position of an insulated return, the London Chamber of Commerce suggested that it was unnecessary to vary the distance permissible between the line and return in different systems. A long discussion took place on this regulation.

Sir COURTENAY BOYLE said he would not decide the point then.

On Regulation No. 14, that "In the disposition, connections, and working of feeders the Company shall avoid injurious interference with any existing wires,"

Sir COURTENAY BOYLE: Now we come to Regulation 14, amended by these words, please,—after the word "shall" insert "take all reasonable precautions to." Now, what has anybody got to say about that?

Mr. SIEMENS said the Institution of Electrical Engineers proposed to strike out the regulation because in Clause 3, which the Joint Committee recommended, the Board of Trade was empowered to make regulations "for minimising as far as is reasonably practicable injurious interference with the electric wires, lines, and apparatus of other parties, and the currents therein, whether such lines do or do not use the earth as a return." Therefore, the whole regulations ought to give the undertakers rules, and the undertakers should be able by following those rules to comply with the recommendation of the Committee. But here, by this regulation, it was all thrown back again on the undertakers.

Sir COURTENAY BOYLE: Only feeders. I made exactly the same criticism when this rule was brought to me that it was practically doing in a rule what the whole rules themselves ought to do. But then it was pointed out to me that this only applies to a feeder.

Major CARDEW: You are not restricted in the position of the feeders to the same extent.

Mr. S. MORSE: It seems to me that this regulation simply repeats Clause 5 in the report of the Joint Committee: the clause which is to go into the Act under which the regulations were made.

Mr. WINTERBOTHAM pointed out that the difficulties which had been suggested by the traction people with regard to the points which the Telephone Company have raised before committees have always been with regard to the working of the lines themselves. The feeders were in no different position from the electric light mains, and why they should not be bound to take reasonable precautions in the running of their feeders, he could not understand. Under Clause 5, which read:—"The undertakers shall take all reasonable and proper precautions in constructing, placing, and maintaining their electric lines, circuits, and other works"—in the course of a number of years they might run these things just as they chose, and it would be a complete answer to any complaints they made that their wires were not metallic.

Mr. SIEMENS: Yes; certainly.

Mr. WINTERBOTHAM said the clause said distinctly that the Board of Trade were to make regulations minimising injurious interference with their electric wires, lines, and apparatus, "and the currents therein, whether such lines do or do not use the earth as a return." Those lines at the end showed most clearly that the Committee intended the Board of Trade to require them to minimise, as far as they reasonably and practically could, injury to their lines, even though they were not metallically looped, and he claimed under that that where feeders were dealt with no such difficulty occurred in making these proper provisions. Where they had no question of having to pick up the current by moving contact or returning the current by the rails, or anything of that kind, no difficulty occurred, and they ought to be put under proper regulations, or Clause 3 of the Act was not given effect to. In fact, by leaving out such a regulation they would be given no protection, because they had to rely upon the protection which the regulations gave them.

Mr. S. SELLON said it seemed to apply in the case of feeders to the fact that where they had feeders for a tramway they must be landed somewhere where they cut those feeders. Probably they would be told by the Local Authorities where they were to put them; but in the case of the telephone people he did not know that their business necessarily limited it; they could go inside or anywhere outside the roads. The Traction Committee could not possibly meet that objection.

Mr. WINTERBOTHAM: As to having no difficulty in running our wires where we like I may say that we have had considerable difficulties. We have no Parliamentary powers whatever, and we must put them where the Local Authorities require it.

Mr. S. SELLON: It is simply a question of inductive disturbance which, according to your own Telephone Clause, is limited to so many feet.

Mr. WINTERBOTHAM said that was the only protection that at all protected them with regard to these feeders, otherwise they would be able to run their feeders without any regard to their wires, merely responding when they claimed that their lines were not metallic looped.

Mr. ARNOT asked if it was at all necessary that the feeders should be duplicated. Did the Board of Trade not entertain the possibility of a single feeder on a short line with a rail return of a sufficient section? In that case, then, the feeder would not interfere with the wires of the Telephone Company.

Major CARDEW: If it was placed too close to them; by the regulation it is proposed that they should not be placed so close as to affect them.

Mr. ARNOT pointed out that the feeders to electric light mains all joined together at the same place, but with a tramway it might be very much to the tramway's advantage to put them at different places, so that one feeder might over-run the other for a considerable distance.

Mr. WINTERBOTHAM said the Board of Trade had suggested a modification of this in the form of "all reasonable precautions," and surely that was not asking too much.

Mr. S. MORSE said Clause 5 was made specially applicable to telephonic and telegraphic communication.

Sir COURTENAY BOYLE: So also is Clause 3.

Mr. S. MORSE thought it was rather a difficult question of construction. Of course the great fight was between the traction people and ehe telephonic and telegraphic people. But it was quite clear, inasmuch as it is said here they "shall take all reasonable and proper precautions."

Sir COURTENAY BOYLE: Mind you, it is existing wires only.

Mr. S. SELLON: The telephones are everywhere. We have got to get there.

Mr. WINTERBOTHAM, referring again to recommendation 5 of the Committee, said that was perfectly clear upon the point—though they might use these wheels and rails, they were to do it in such a manner as to mitigate as far as practicable any injurious effect to telephonic companies. They were entitled, he argued, to Clause 3; Clause 5 had nothing whatever to do with Board of Trade regulations.

Mr. S. MORSE: I think you will admit that feeders are included in Clause 5.

Sir COURTENAY BOYLE: Of the Act certainly.

Mr. S. MORSE asked, if so, what did it give more by saying that they should take all reasonable precautions to work feeders—did it limit their taking reasonable precautions to work other matters, because the expression of the one in this regulation might limit the obligation upon the tramway company as to other matters; and if the word "feeder" was limited in 5 then, he submitted, that if regulations were made which gave the Telephone Company more rights than were given by Clause 5, the Board of Trade would legislate in favour of the Telephone Company.

Sir COURTENAY BOYLE: How do you answer Mr. Winterbotham's objection as to the proviso about three years in Clause 5 of the Act.

Mr. S. MORSE said the provision of the three years, as he understood it, was merely with regard to the duplicating and twisting of their wires. The proviso was that "the undertakers should be deemed to take all reasonable and proper precautions if and so long as they adopt and employ, at the option of the undertakers, either such insulated returns or such uninsulated metallic returns of low resistance, and such other means of preventing injurious interference with the electric wires, lines, and apparatus of other parties and the currents therein, as the Board of Trade shall direct." "Provided also that if at the expiration of [——] years"—that meant to say that they must have some time given to them. Recommendation 10, he thought, said that to enable them to protect themselves a period of two years might be allowed.

Mr. SIEMENS said the clear intention of the Committee was that the telephone companies were to take care of themselves. In giving them three years to do it they gave to them three years to put up the metallic circuits.

Mr. WINTERBOTHAM said that, notwithstanding that Clause 3 was drawn, which intimated to the Board of Trade that their regulations were to minimise as far as was practicable the interference with wires whether they used the earth or not, they recognised the fact that the Telephone Company had a mass of wires in existence at the present time, and that reasonable protection should be given. He did not for a moment say that they were to have protection which put them to an enormous expense.

Sir COURTENAY BOYLE thought the regulation as amended had very little effect one way or the other. He would consider the argument, but he did not think it mattered if the regulation, amended as taking all reasonable precautions, were limited or inserted.

Mr. S. MORSE: Would you consider the question of giving a certain date for the existing wires.

Sir COURTENAY BOYLE: Yes; if we put it in.

The Conference was then adjourned to Friday.

FRIDAY, FEBRUARY 23RD.

The Board of Trade Conference was resumed to-day, Sir Courtenay Boyle again presiding.

Regulation 15, as drafted, was: "The Company shall so construct and maintain their system as to secure good contact between the motors and the line and return respectively, and they shall not allow sparking to occur at the rubbing or rolling contacts in any part." To this the Institution of Electrical Engineers proposed an amendment that "they shall not allow more sparking to occur at the rubbing or rolling contacts than is considered reasonable by the Board of Trade."

Mr. SIEMENS, in supporting the amendment, said the regulation as drafted amounted to an absolute prohibition of sparking, which was an impossible condition to fulfil.

Digitized by Google

Sir COURTENAY BOYLE said he thought the best thing was to adopt the suggestion of the London Chamber of Commerce, and read it together with No. 17, which provided that all reasonable precautions should be taken.

Mr. WINTERBOTHAM said that the amendment of the Telephone Company should be adopted, requiring the use of brushes and other proper means. The disturbance had been vastly greater, owing to the use of a rubbing contact. As long as the contact was not practically broken they did not consider the irregularity of the contact produced most tremendous disturbances and variations in the current.

Mr. STEPHEN SELLON objected that uniform current was absolutely impossible to maintain. Dirt would get on to the brushes, and then they would not provide the perfect remedy which Mr. Winterbotham suggested. Unless they could run the wire absolutely the same distance from the rail it would be impossible to have uniform contact.

Mr. LANGDON said that with respect to railway signals it was important there should be as little disturbance and variation in current as possible. He thought something more definite than the relative term "good contact" should be adopted, but would be satisfied that it should remain under the direction of the Board of Trade.

Mr. SYDNEY MORSE suggested that the "best means available at the date of construction" should be required, as otherwise traction companies might be put to unnecessary expense in adopting what at the moment appeared to be the best means available, and then shortly afterwards be required to replace it by what was then considered to be the best means.

Sir COURTENAY BOYLE pointed out that necessarily the whole thing would be under the direction of the Board of Trade, and the penalty to satisfactorily comply with the regulations would be the withdrawal of the Board's sanction to use electricity. Therefore it did not strengthen the matter by referring to the Board of Trade at each regulation.

After further discussion, Nos. 15 and 17 were taken together and framed thus:—

"(15) The Company shall so construct and maintain their system as to secure good contact between the motors and the line and return respectively."

"(16) The Company shall adopt the best means available to prevent the occurrence of undue sparking at the rubbing and rolling contacts in any part, and in the construction and use of their generator or motors."

The next regulation ran as follows:—"In working the cars the current should be varied as required by means of a rheostat containing at least 20 sections, or by some other equally efficient method of gradually varying resistance." Upon this, the Association of Municipal Corporations observed—"The selection of 20 sections in the rheostat is perhaps somewhat too definite. What is really required is a means of varying the current continuously without sudden changes. It would be better to insist that the starting and stopping of cars shall be effected by a continuously varying resistance."

Dr. FLEMING, in support of the amendment, said that instead of binding it down to 20 sections the current could be varied by a carbon rheostat, for instance, which would prevent changes and injurious action on neighbouring lines

Major CARDEW said the regulation only prescribed the minimum number of sections, and did not prevent a larger number being used.

Mr. HOLROYD SMITH said 20 was a very great number, because if they had a car and wanted to drive from both ends of it, with 20 points in the resistance, they must have 20 wires running the whole length of the car.

Major CARDEW: You must mechanically gear your rheostat.

Mr. HOLROYD SMITH said they might put the rheostat in the middle, but would get a complication with that, especially with a bogey car.

Mr. SIEMENS said he did not think the wording of the Board of Trade could be improved upon.

Sir COURTENAY BOYLE: You do not think 20 sections is too many?

Mr. SIEMENS said he thought they were too few, because the steps ought to be so that the difference in voltage from one step to the other was very low, otherwise sparking would occur. If the steps were too large, when they put in the resistance an arc would come between the two steps instead of the current going through the resistance, which would upset all the arrangements, spoil the switch, and bring about an accident. There was no practical difficulty in putting the switch in the middle and having a cord from each end of the car to manipulate it.

Sir COURTENAY BOYLE said he could not go too deeply into the details of the construction of the rheostat. The regulation was an elastic one and must stand.

On Regulation 18, with the insertion of suggested drafting amendments by the Institution of Electrical Engineers, the first part was agreed to as follows:—

"Where the line or return, or both, are laid in a conduit, the following conditions shall be complied with in the construction and maintenance of such conduit.

"(*a*) The conduit shall be so constructed as to admit of easy examination of and access to the conductors contained therein, and of all insulators and their supports.

"(*b*) It shall be so constructed as to be readily cleared of accumulation of dust or other *débris*, and no such accumulation shall be permitted to remain."

Sub-section (*c*), as drafted, was: "It shall be laid to such falls, and so connected to sumps or other means of drainage, as to automatically clear itself of water without danger of the water at any time reaching the level of the conductors." The Institution of Electrical Engineers proposed to strike out the words "at any time."

Mr. SIEMENS stated that if there was a sudden flood or anything of that kind they could not prevent the water reaching the conductors. In the interests of the Tramway Company every precaution would necessarily be taken, but the regulation as it stood imposed an impossible condition.

Sir COURTENAY BOYLE said that *force majeure* was always allowed to prevail against any regulation.

Major-General WEBBER said that the interpretation of the regulation might require the construction of a conduit of exaggerated depth.

Mr. HOLROYD SMITH said that at Blackpool sometimes a wave would sweep over the whole promenade and over the line, but it was away in two seconds.

Major CARDEW said of course a momentary contact was not any source of danger, but if the conductors were to remain in contact with water for an hour or two it was a different matter.

Mr. HOLROYD SMITH said that then the working would be stopped as the current would be gone.

The words "at any time" were struck out.

Sub.-Sec. (*d*), as drafted, was: "If the conduit is formed of metal, all separate lengths shall be so jointed as to secure metallic continuity for the passage of electric currents, and where the rails are used to form any part of the return they shall be electrically connected to the conduit by means of copper strips having a sectional area of at least one sixteenth of a square inch, or other means of equal conductivity at distances apart not exceeding 100ft. Where the return is wholly insulated and contained within the conduit the latter shall be connected to earth at the generating station through a high-resistance galvanometer suitable for the indication of any contact or partial contact of either the line or the return with the conduit." It was decided this should follow the same lines as the drafting of No. 4, which had been reserved by the Board.

Sub.-Sec. (*e*) read: "If the conduit is formed of any non-metallic material not being of high insulating quality and impervious to moisture throughout, and is placed within 6ft. of any pipe, a non-conducting screen shall be interposed between the conduit and the pipe, of such material and dimensions as shall provide that no current can pass between them without traversing at least 6ft. of earth." The Institution of Electrical Engineers proposed to substitute for this the following paragraph:—"The leakage current shall be ascertained daily before or after the hours of running, when the line is fully charged, and if at any time it shall be found to exceed half an ampere per mile of track the leak shall be localised and removed as soon as practicable."

Major CARDEW thought the provision of the sub-section rather important. It was only in case of the conduit being formed of material which was not metallic, but which at the same time was not of high insulating quality and not impervious to moisture. It was that particular class of material which it was so difficult to deal with electrically, and those partial conductors which gave trouble in leakage.

Mr. MONIER WILLIAMS, on behalf of the Gas Company, protested against any alteration of the sub-section, which had no doubt been inserted by the Board of Trade, after due consideration, for the protection of the companies having pipes in the streets.

Major CARDEW proposed an addition which he thought might satisfy the traction people:—"Or the conduit itself shall in such case be lined with bitumen or other non-conducting damp-resisting material in all cases where it is placed within 6ft. of any pipe."

Mr. MANVILLE observed that the most non-conducting of substances when entirely buried in the earth became practically no obstruction to the passage of the current. He had tried some experiments with asphalte underground, and it was apparently a good conductor. Once it was buried in the earth he believed it would be practically impossible to put a shield between the conduit and the pipe that would prevent a current passing into the pipe just as if that shield did not exist.

Major CARDEW said the current would pass, but not at that place. Mr. Manville had not quite got into his mind the idea that where there was a pipe very close to the conduit, they wanted to prevent an electrical current at that place. He quite agreed that it would be impossible to insulate the current entirely by any such means, but they could prevent the current damaging the pipe.

Major-Gen. WEBBER said the regulation would practically prohibit a line being constructed in any narrow street, because it must run for a considerable distance within 6ft. of gaspipes.

Sir COURTENAY BOYLE said there was no subject in which the public were more interested than in the prevention of danger to the gaspipes by leakage.

Major CARDEW pointed out the various alternatives: First, they had the option of making the conduit of iron or other metal; secondly, of making it of a material of a highly insulating quality, and impervious to moisture; thirdly, if the material were not highly insulating and impervious to moisture, of placing a screen as proposed in the regulation (*e*); and, fourthly, of lining the inside of the conduit with a damp-resisting material. Surely out of those four a practical way of getting along could be found.

Mr. MONIER WILLIAMS and Mr. COLLINS expressed their preference for the clause as it stood, and Mr. LANGDON said that he saw no difficulty in it.

Mr. STEPHEN SELLON and Mr. MANVILLE agreed with Major-Gen. Webber's view of the matter.

Mr. SIEMENS thought that with the addition proposed by Major Cardew, and the alternatives he had shown them, the clause was acceptable, and that there was no great difficulty or expense in lining a conduit with bitumen.

Sir COURTENAY BOYLE said he would let the regulation stand with Major Cardew's addition.

Mr. SYDNEY MORSE said that with reference to sub-section (*d*), the London Chamber of Commerce observed, "It does not seem satisfactory to electrically connect lengths of conduits together, especially where a complete metallic return is used, on the grounds that a fault might cause a complete breakdown in the whole system, if metallic continuity was insisted upon, instead of only a partial one." He proposed that the commencement of the sub-section should read, "If the conduit is formed of

Digitized by Google

metal, all separate lengths shall," adding the words, "save where both line and return are laid within the conduit," "be so jointed," &c.

Major CARDEW said he was afraid they could not accept that wording. They had had a good deal of experience of the dangers affecting metallic conduits which were not metallically connected throughout.

Sir COURTENAY BOYLE said they could not accept the amendment.

Mr. SIEMENS, on behalf of the Institution of Electrical Engineers, proposed that the paragraph relating to leakage currents, which was originally proposed in substitution of (e), should be adopted as a separate sub-section (*f*).

Mr. WINTERBOTHAM suggested that whatever was done with Regulation 10 as to the stopping of cars should be done here.

Mr. SIEMENS: Yes, that would be all right.

Sir COURTENAY BOYLE said that 24 hours would be given to remedy the leak, or the running of the cars must be stopped.

Several drafting amendments having been considered,

Sir COURTENAY BOYLE read a new Regulation, which had been drafted by Major Cardew, as follows: —"Where in any part of the tramway the line is erected overhead by means of insulators to iron or other metallic supports set in the ground, and the return in such part is uninsulated, bases of each support shall be electrically connected to the return by means of a metallic conductor, which will not be appreciably heated by a current of a hundred amperes."

Mr. DICKENSON said he had been back to South Staffordshire, and temporarily connected seven poles three miles distant from the generating station. The result was that immediately they were connected there was a rise of 10 amperes from their earth-plate connections. That brought them over the limit allowed by Regulation 5 as to the quantity of current that they were permitted to collect from their earth-plates. If that regulation were amended so as to permit of the quantity of current being collected from the earth-plates he had no objection at all, but if they connected the whole of the poles in the South Staffordshire system it was equal to putting in 6,000 superficial feet of earth plate. The regulations generally prohibited the return being connected. It must be separated from the general mass of earth, but this regulation connected them to the general mass of earth, and he believed if the whole of their poles were connected they should get quite three-fourths of their current back through the earth. It depended upon the conductivity of the earth in the district, and also upon the form of the line. If the line was a complete circle, and the generating station was in the middle, and the whole of the poles were connected, of course the current would take the shortest path and the path of least resistance, and practically none of it would come back through the rails. If Regulation 5 as to the earth connections to be made were insisted upon, they would only get 5 per cent. of the output of the generating station back through the return.

Mr. LANGDON submitted that this proved that the rails were not performing their duty. The Joint Committee said that these open returns were to be of such a capacity as would carry the current back without injuriously affecting the interests of other people.

Mr. DICKENSON said they were of such a capacity. Their returns were properly metallically connected. In addition to having a copper strip across them they had a special fish plate which the joint of the rail rested upon, and clipped it at the side, and the section of the rail would permit of eight or ten times as much current going back with the resistance allowed by the Board of Trade. The experiment clearly showed that it went back through the earth in spite of all this when they were connecting to the earth, although just before they did that they were well within the limit of the Board of Trade.

Mr. LANGDON said they had been very seriously affected at Walsall by these currents getting into earth and passing on to their wires.

Mr. SINCLAIR thought that when the two rails were properly and electrically connected together as forming the return, all would agree that it was impossible for the current to leave these rails and go into the earth and come back by it only in proportion to the resistance offered by the combined rails.

Mr. SIEMENS pointed out that it was quite impossible to prevent the electricity going into the earth by lowering the resistance of the return conductor. Electricity, if it had different ways to choose between two points, would always follow all the ways, and would be inversely to the resistance of the different ways. If the resistance was 99 times greater than the other, then the higher resistance path would take a hundredth of the electricity, and the low resistance conductor would take 99 parts. Therefore his experiment conclusively proved that the path through the earth was made easier for the electricity by making the connections which Mr. Langdon proposed, and therefore a greater part of the electricity was diverted through the earth by providing better means for the current to enter the earth. He would also call attention to a point which the railway companies did not talk about. It really took three manipulations before a block signal was interfered with. A stray current from the tramway or an ordinary earth current could possibly give in one station a signal which would indicate that station A wished to ask station B whether the line was clear. That might induce the signalman in B to answer back that the line was clear, but that would not lower the signal; the signalman at A would simply say "What did you give me 'line clear' for? I did not ask you for that." As long as the railway used earth, any current, meteorological or otherwise, would interfere with them just as much as any stray current from the tram line could do. Moreover, in these regulations they had laid down that the difference of potential between the extreme point of the tramway return and the station should be 6 volts. If Mr. Dickenson had brought down his difference of potential to 6 volts he would not have had 10 amperes.

Sir COURTENAY BOYLE said, to his mind, there was a great deal in the point that three operations were required before they got in danger on a railway.

Mr. LANGDON said when a train was about to be started to a point the signalman rang a bell at the station to which it was about to advance, which told the man there. He replied on the bell, and by-and-by they gave a tick on the needles of the instrument by pushing over the handle to one side or the other, as the case might be; then that was answered, and if that answer was correct that enabled the man at the other end simply, without ringing the bell again, to pass the needle of the instrument over to either "block" or "clear." It was just at that point where the difficulty came in. Supposing just at that instant when the man was about to give the line "block" signal a tramway current passed upon the wire and gave the line "clear" signal, an accident might happen.

Major-Gen. WEBBER said this new regulation was practically bringing to the test the possibility of insulating the line as carried on the poles at the point of the insulating supports. They knew that no insulation ever had been put upon poles which would resist what was called weather leakage, and that in times of heavy rain the mass of the current would return directly from the return into the line. He thought it would be very unwise to introduce a regulation to protect railway companies when they could protect themselves so thoroughly. By connecting the rails when they were used as an uninsulated return to the iron poles they would cripple the construction of all their possible future country electrical tramways.

Mr. S. MORSE said evidence was given before the Joint Committee of an accident having arisen at Walsall when, as the result of some leakage, "line clear" was given when there was a train on the line. It was also proved that the railway companies could get over the difficulty at a small expense.

Mr. SIEMENS said the Committee clearly indicated that the telephone and railway companies ought to protect themselves by adopting metallic returns.

Sir COURTENAY BOYLE thought they had discussed the point very fully. It was impossible for him to decide the question, which was an absolutely scientific and electrical one. He must act on the advice of the electrical expert attached to the Board of Trade, Major Cardew, and he thought the best thing would be for Major Cardew to go down to Staffordshire, and see exactly what was the nature of Mr. Dickenson's experiments, and to consider how far those experiments justified his contention. Major Cardew should then submit a further draft of the clause, which the Board of Trade would consider, if necessary, in further consultation with Mr. Langdon and the gentlemen affected by it. It was possible they might have to have another meeting merely for this, only the thing must be done quickly, as they were getting very short of time.

Mr. SIEMENS proposed the addition of a regulation providing that where overhead lines are used the company should erect a guard wire, to prevent any previously erected wires from coming into metallic connection with the conductors carrying the tramway current.

Sir COURTENAY BOYLE thought they might be perfectly sure that the guard wire would be there, whether under this regulation or not. He would undertake that with the words "where necessary" it should be inserted somewhere.

On a suggested regulation by the associated railway companies, that the most effective means of preventing interference with the railway wires would be found in laying the line and "return" traction wires on insulated supports within a metal culvert,

Sir COURTENAY BOYLE said his hands were tied by the report of the Joint Committee on that point.

The Gas Light and Coke Company suggested the advisability of inserting a prohibition forbidding connections with gaspipes.

Mr. MONIER WILLIAMS said the point was one of great importance to them.

Sir COURTENAY BOYLE thought they were bound by the report of the Joint Committee. He was afraid the Board of Trade had no power to insert a "damage" clause, though he would further consider it.

Mr. MONIER WILLIAMS suggested, as a proviso to Regulation 5, with regard to the making of earth connections: "Provided always that, before allowing any departure from your modification of this regulation, such officer of the Board of Trade shall give to any company owning pipes in the vicinity an opportunity of objecting thereto, and of appealing to the Board of Trade, who shall hear and adjudicate upon its objection by an arbitrator appointed by the Board in the usual way."

Sir COURTENAY BOYLE said he was perfectly ready to make it the duty of the officer of the Board of Trade to consider any objections that were sent to him, but did not think the officer could be asked to go about hunting up objections. He would consider the point.

Mr. SYDNEY MORSE understood that these regulations in their present form were to be added to clauses to be inserted in future Bills.

Sir COURTENAY BOYLE: I am not sure about that.

Mr. S. MORSE: There are a great many tramway companies which have electrical powers with Bills which were passed previously to the Joint Report. These regulations would be rather difficult to interpret if they were put by themselves to those tramways when they come to equip themselves electrically, unless the clauses were incorporated into the regulations, and the whole thing applied to those tramways.

Sir COURTENAY BOYLE: I am considering this point with the authorities of the House at the present moment. I think that the clauses will have to be inserted in every future tramway Bill or Provisional Order, but I do not think the regulations ought to be scheduled to the clauses.

Mr. S. MORSE asked how the case of a tramway company would be dealt with who had already acquired their Act without these clauses when they came to equip themselves electrically.

Sir COURTENAY BOYLE: I think we shall recite the clauses in the regulation.

Mr. S. MORSE: Making the two—the clauses and the regulations—applicable?

Sir COURTENAY BOYLE: I cannot make the clauses applicable; Parliament must make them applicable.

Digitized by Google

Mr. S. MORSE: May I ask the Board of Trade to consider whether they will introduce a general Bill which would make these clauses applicable to the Acts already in force where the clauses are not inserted. There are, I think, over a hundred.

Sir COURTENAY BOYLE: That is such a very important question; in these days it is not very easy to get a general Act about anything, but if there is sufficient desire on the part of tramway companies at present having Acts, and desiring to equip themselves electrically, that there should be a general Act embodying these clauses, the Board of Trade will further consider it, but until the pressure comes before us in sufficient quantity I think that we should hardly be able to act.

Mr. S. MORSE said there was this difficulty, that the tramway companies without these clauses were in great trouble as to how they were to carry on their business without actions from the Telephone Company.

Sir COURTENAY BOYLE: Then they had better apply to us for regulations, and we will recite the clauses and impose the regulations.

Mr. S. MORSE: Then, sir, we do not get the protection of the clauses.

Sir COURTENAY BOYLE: Then why do you not go to Parliament?

Mr. S. MORSE: Because when it is a question of a hundred companies or corporations going one Act might not cover the whole question.

Mr. WINTERBOTHAM submitted that the parties having these Acts had no *locus* to come in now and ask the Board of Trade to put an end to agreements which they had submitted themselves to.

Mr. S. SELLON: I understand you must have a large number of applications for driving home the question.

Sir COURTENAY BOYLE: I think we must. It is very possible we may have to have a general Act. If the pressure arises to a certain amount we may do something.

Mr. WINTERBOTHAM: I hope I shall be able to do something on the other side.

Sir COURTENAY BOYLE then thanked the members of the Conference for the assistance they had given the Board of Trade, and the Conference terminated.

ON METHODS OF TESTING THE MAGNETIC QUALITIES OF IRON.*

BY GISBERT KAPP.

The industry generally comprised under the term "heavy electrical engineering" has of late years made such rapid progress that the question as to the kind of materials to be used has become of great importance. As regards the copper wire required in the construction of electrical machinery, certain standards regarding the size and conductivity have from the very first been adopted. The metal of commutator plates, size of wearing surface, type and number of brushes, dimensions of resistance coils, and other purely electrical parts of the machinery, have also, as a rule, been specified; but as regards the iron used, no attempt was at first made to define it by specification. Makers of dynamos, for instance, broadly distinguished between cast iron and wrought-iron field magnets, and got out their designs with reference to the magnetic properties each of these two kinds of iron was assumed to possess; but there was no certainty that the iron obtained did actually possess these properties. If the machines turned out according to design, well and good; if not, then the speed or excitation had to be altered so as to get the output right. This was the old and unscientific method of building electrical machinery. The modern method is very different and far more certain. The manufacturer of a dynamo knows exactly what kind of iron he is using, and he is thus able to predetermine the performance of the machine with a degree of accuracy which formerly was impossible. This is especially of importance in large machines, as experimental runs to determine the characteristic at full load are not easily made, and are always expensive. In such cases it is preferable to cut a sample from the magnets, test it magnetically, and use the results of this test in designing the winding.

In some cases it is not even necessary to cut off samples and test them, as the manufacturers of forgings and castings for magnets offer now to supply these so as to conform to a certain magnetic standard, commonly defined by means of a curve in which the abscissæ represent magnetising force and the ordinates induction. Provided, then, the iron maker supplies exactly the material which he has promised, the winding of the machine can be designed without any preliminary experimenting. Iron makers are now keenly alive to the importance of this subject, and produce most excellent material. The testing of iron plates intended for use in alternators and transformers is another of those questions which had to be faced by manufacturers who wished to attain perfection in their work. As regards transformers, it will probably be admitted by all that the quality of the iron is the most important factor in the whole design. To make a good dynamo with inferior iron is still possible; we need only use enough of it, and spend enough money on the copper to make up for the deficiency in the iron. With transformers this cannot be done. If the iron is bad, no increase in its bulk and no amount of money we may spend on copper will enable us to turn out a good transformer. The important point with transformer plates is not the higher or lower permeability, but the waste of power by hysteresis and eddy currents; although to a certain extent the two go together, in the sense that a very soft iron having high permeability also has, as a rule, a small hysteresis loss. Plate makers, recognising the importance of small hysteresis, now offer their material with a guarantee that the loss with a given induction and frequency shall not exceed a certain amount per pound.

Admitting, then, the necessity for magnetic tests of iron, the question as to method arises. There can be no doubt that the methods adopted by Dr. Hopkinson and Prof. Ewing in their classical researches give the most accurate results; but the very perfection of these methods forms a drawback to their adoption in engineering works where highly trained experimenters cannot be found. I have therefore adopted other methods, which do not aim at absolute accuracy, but which can be used by any one of the staff generally found in the test room of electrical engineering works. The apparatus required is on the table, and I venture to bring it before you because it has been in use for some years, and has given results which were always found sufficiently accurate for all practical purposes.

It will be convenient to divide the subject into two parts—one dealing with the testing of magnet iron, and the other with the testing of transformer plates.

Testing Machine for Iron Bars.

This is shown twice full size in the wall diagram (Fig. 1)*. For the principle on which it is based I am indebted to a little instrument devised some four years ago by Prof. Silvanus Thompson, and called by him a "permeameter." In it the induction through the sample bar is measured by the force required to pull the bar away from another piece of iron; and, as the induction is proportional to the square root of this force, it is clear that any small error in the measurement of this force results in a still smaller error in the determination of the induction. Thus, if his spring balance were wrong by 2 per cent., the error in estimating the induction would only be 1 per cent. So far, then, as the determination of B was concerned, the permeameter appeared to be an exceedingly accurate instrument; but this alone is not sufficient. We must have the relation of B and H, and, as part of the total ampere-turns applied is required for the magnetic circuit outside of the sample, certain corrections must be applied in the determination of H. It was mainly with the object of making these corrections both small and definite that I altered the design of the Thompson permeameter and made it in the form shown on the diagram. The instrument consists of a heavy rectangular frame, made of the best Lowmoor iron, well annealed. Within the frame is fixed a solenoid with subdivided winding, so that a variable, but known, number of turns can be placed in circuit by using the various terminals provided on the instrument. The object of this arrangement is to keep the current within such limits as will ensure the greatest accuracy in its measurement, whilst the magnetising force is varied between very wide limits. A reversing switch is inserted to facilitate the investigation of the complete cycle.

The sample consists of a bar accurately turned, and faced at the lower end. The bar is kept larger at the upper end, where it passes through a hole in the frame—a fairly tight fit—and it is centred near the lower end by a little gunmetal ferrule. Below the bar is a soft iron plunger, guided in a hole in the frame, and provided with an attachment for holding a scale-pan and weights. The plunger is made larger than the bar, and has a fine hole drilled through it to ensure good contact over the rest of the surface. The dimensions of the plunger and the hole in the frame being accurately measured, it is, of course, quite easy to determine by calculation how much of the ampere-turns provided is required to overcome the resistance of the annular air space; and this is the only important correction required. The other corrections, such as the magnetic resistance of the frame, or that of the joint between the sample and the frame at the top, are quite trifling. Even the correction for the resistance of the air space is only important for low inductions. For inductions above 10,000 it becomes relatively small, and above 15,000 quite negligible. The method of using the instrument is as follows:—The sample, with its end carefully faced, is inserted from the top, and a small current sent through the solenoid, using the smallest number of turns. The plunger flies up against the sample and sticks there. The scale-pan is attached, and weighted until the plunger comes off. The exact point at which the weight overcomes the magnetic attraction is best determined by slightly varying the current by means of a rheostat; and I may mention that it is necessary to use a storage battery to provide the current. To work directly from a dynamo is impossible, as the slight variation in current produced by the irregularity in speed of the engine, or the flicking of a belt, is quite sufficient to make the tearing-off point uncertain.

* Paper read before the Institution of Electrical Engineers, Thursday, February 22nd.

* We have not received copies of the diagrams illustrating Mr. Kapp's Paper, and Figs. 2 and 3 are from sketches made at the meeting. [Ed. E.]

The current, number of turns in the solenoid, and the weight are now increased step by step, then decreased again to zero. The current is then reversed, and the operation repeated, so as to obtain the complete cycle. The values recorded are ampere-turns and tearing-off weight, in which is, of course, included the weight of the plunger and scale-pan. The greatest weight supported by a half-inch sample bar of good iron is about 45lb. I need not detain you by giving in detail the calculations for finding the relations between ampere-turns and H, or weight and B, nor the values of the corrections*, since these are purely elementary matters, and can be worked out for any testing machine of this type if its dimensions are known. The time occupied in testing a sample through a complete cycle is about an hour; one man manipulating the weights, and the other the current. The latter also books the readings.

I have used the apparatus before you in testing large numbers of samples of cast iron, wrought iron, and mild steel submitted to me for investigation by different iron makers, and some of the curves obtained are on the table. For obvious reasons, I do not mention any particular maker of magnet steel; but I may say generally that the samples of steel submitted to me were very good, and in some cases better than wrought iron. The good qualities of mild steel, as revealed by the testing machine, were fully confirmed when the same material was used in dynamos, and thus tested on a large scale.

Testing Machine for Transformer Plates.

My first attempt to make such a machine was a failure; but, as failures are sometimes as instructive as successes, I have placed the machine on the table for your inspection. In this machine I did not measure the power lost in the sample, but endeavoured to get an approximate means for comparing the permeability of different samples. An iron ribbon is coiled up to form a closed ring, and this is wound on opposite sides with coils so connected as to produce consequent poles over the two sides kept free from winding. The sample is made up of narrow strips into a flat bar, which is laid across the poles to form a magnetic bridge. The sample is surrounded by a pilot coil, and this is connected with an electrostatic voltmeter. If the same current is always sent through the main coils, and at the same frequency, then the volts produced by the pilot coil are supposed to give, roughly, an indication of the comparative value of the samples. The method was a

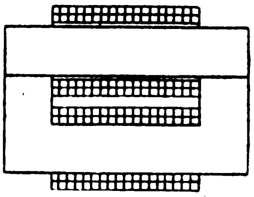

Fig. 2.

failure, partly because permeability is not an absolutely reliable guide in estimating hysteresis loss, but chiefly because the uncertainty in estimating the magnetic resistance of the joints completely swamped any small differences that might have existed in the permeability of the samples. I therefore promptly abandoned this instrument, and set to work on another which would give directly that what we want to measure—namely, the losses at given inductions.

This instrument, which I finally adopted, is shown on the table, and in the diagram (Fig. 2). It consists essentially of a closed magnetic circuit of rectangular shape, the two longer limbs being enclosed in exciting coils. One long limb and the two uprights are composed of plates in one piece; the other long limb is formed by the sample plates, which are laid together so as to make up a certain weight, and are then bound together with tape and inserted through the top coil. The sample is fixed by wooden wedges. The coils are connected with a source of alternating E.M.F. (sine function) through a wattmeter, and the instrument is thus ready for use without further preparation beyond making up a bundle of plates into a sample bar and inserting the latter. The instrument is calibrated once for all by making the sample and the fixed part, or yoke, of the magnetic circuit out of the same quality of plates, measuring the loss of power at different inductions, and apportioning the losses between the yoke and sample according to their weights. When testing other samples the total loss is measured by the wattmeter, and from this is deducted that portion of the loss which is occasioned by the iron which forms part of the instrument, the remainder being the loss in the sample. A correction must be made for the loss of power resulting from the ohmic resistance of the two coils, but this is exceedingly small. The induction is found from the E.M.F. applied to the coils and the frequency. In order to have a wide range of induction, and yet keep the measurements of current and E.M.F. within the limits most convenient for the instruments at hand, the coils are subdivided, and suitable terminals are provided. The resistance of the joints between the sample and the yoke is immaterial, as it influences only the current, but not the power.

The upper curve in Fig. 3 shows average results obtained in testing samples of plates furnished by several different suppliers of transformer iron. I say advisedly "suppliers," and not makers, because iron merchants are, as a rule, disinclined to give the name of the maker. In fact, I have had a case in which two samples supplied by rival merchants gave precisely the same curve, and on making inquiries I found that the iron came indeed from the same maker, but was sold under different names. The lower curve in Fig. 3 shows the results obtained with the best sample I ever tested. As it is not my purpose, and as it would indeed be improper to advertise any particular maker in a paper of this kind, I trust you will not expect me to give his name. The curves are, for convenience in use, plotted under the supposition that the frequency is 100. The abscissæ give induction, and the ordinates loss of power in watts per pound of iron. The thickness of plates varied between 10 and 13 mils. Within these limits I believe that the thickness has only a very small influence on the

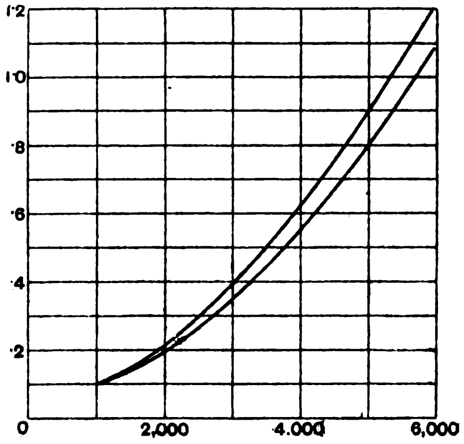

Fig. 3.

loss—at any rate, I have not been able to detect any such influence; and this confirms an admirable investigation by Prof. Ewing, in which he showed, on theoretical grounds, that a reduction of thickness below about 13 mils is of no advantage. It is, of course, quite easy to test transformer plates by taking a known weight of stampings and making them up in a transformer with only one coil (preferably a low-pressure coil). If the same coil be always used for this purpose, the results will be perfectly reliable. The method is, however, tedious when a number of samples has to be tested, as time is wasted in building up and taking to pieces again the plates between each set of tests. With my testing machine all the samples can be prepared beforehand, and slipped in quickly one after another, so that the whole series of tests can be performed under the same conditions and by the same men. The facility with which samples can be changed is also of value if it should be necessary to verify any doubtful point in the curve obtained in a previous test.

There is another and very obvious method of testing transformer iron, and that consists in making up a complete transformer with the sample plates to be tested. Apart from the waste of labour entailed if the iron should turn out bad, this method is very uncertain. The reason for this uncertainty is that we test, not the iron alone, but the complete transformer, and we are thus left in doubt as to how much of the measured loss is really due to the iron. Theoretically the whole loss is due to the iron, but in practice this is seldom the case. When testing a transformer immediately it is completed, and again after some weeks during which it has been regularly at work, you will find that its losses have become less. This I believe to be due to the coils having become thoroughly dry, and their insulation higher. A very small electrical leak in the high-pressure winding may easily lead to a waste of power, which, although small in itself, and not capable of doing any damage, is still appreciable when compared with the true iron loss. Take,

* In the instruments exhibited, the corrections for top of sample, frame piston, and air-resistance collectively, amount to $\frac{2·37}{1,000}$ B ampere-turns, to be deducted from the total ampere-turns. Thus, for B = 12,000, which would be the lowest induction of practical importance, 28·5 ampere-turns would have to be deducted from a total of about 300; whilst for B = 15,000 the corrections would be 35·5 to be deducted from a total of about 1,500, and for higher inductions the correction becomes quite negligible. If P is the tearing-off weight in pounds, $B = 2,973\sqrt{P}$; and if X represents the corrected ampere-turns, $H = \frac{X}{20·2}$.

for instance, a 4-kilowatt transformer wound for 2,000 volts. Its iron loss would be about 2 per cent., or, say, 80 watts. Suppose, on testing this transformer, you find that the loss is not 80, but 100 watts. You might then conclude that the iron has 25 per cent. more loss than it ought to have, and you would condemn the sample. This might, however, be an unjust verdict. The extra 20 watts measured might very well be due to a general leakage of current across the turns of the high-pressure coil. The leakage surface is large, and the pressure is large, so that the current density of the leak is very small, and no damage will be done. The leak vanishes as the transformer gets dry, and thus may be explained the curious fact that transformers get better after use. The moral of this is that to do justice to a transformer the final test should only be taken after it has been at work for some time.

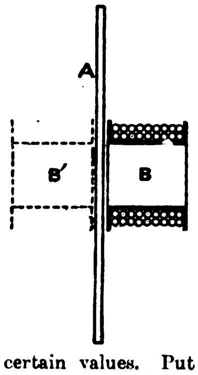
In conclusion, I wish to express my thanks to Messrs. Johnson and Phillips for the loan of the testing machines here exhibited.

DISCUSSION.

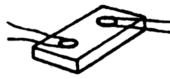
The following is an abstract of the Discussion which followed the reading of Mr. Kapp's Paper; speakers whose remarks are prefaced by an asterisk, have returned their proofs revised :—

* Prof. HUGHES said he had not had any experience with the high induction of iron, as all that he had been working at with iron was with very feeble currents. But the method of testing in this machine was one which he had adopted in his printing telegraph instrument. The armature was held by the standing magnet, and it was let loose by the current reversed to it. In that case they had the holding power just as in this, and it was a measure of the current. But they had this difficulty, that if the surfaces were not perfectly exact there was always a slight variation in the regulation. With the printing telegraph instrument, if they took it to pieces there was always a variation in the adjustment, and they had to readjust it; and as the armature in Mr. Kapp's arrangement would have fresh surfaces brought into contact at each different test, he would like to ask Mr. Kapp if he had met with this difficulty, and what means he employed to ensure an absolute similar contact throughout different tests.

Prof. S. P. THOMPSON said Mr. Kapp had referred to his instrument, which he devised some four or five years ago. The second form of instrument that was made for him by Messrs. Nalder Brothers, was very much better, in fact, so much better than the first that he was inclined to believe that it was a little better than Mr. Kapp's. As the Institution existed for the criticism of Papers read, Mr. Kapp would not object to his criticising his instrument. Whilst it was quite true that they might make corrections for various sources of possible error, such as the magnetic reluctance of other parts of the apparatus than that under measurement, yet still it seemed better to him that when instruments of that kind had to be designed they should be designed so as to avoid all sources of correction that could come in afterwards to add to the calculations. In designing a metre-bridge it was necessary to take care that all the brass-work was very thick and conducting compared with the wire stretched along and which was to serve as the standard resistance, in order that the corrections, the very quantities which might have to be applied as corrections, should in themselves be so small as to be for all practicable purposes negligible The cross-section of the mass of iron surrounding the coil and plunger was in his instrument 200 times as great as the cross-section of the rod that served as plunger. Then again, his plunger, which was in itself the test-piece, was made longer and thinner in proportion than was the case in Mr. Kapp's instrument, for the express purpose of eliminating the error due to possible badness of contact. It would be remembered that in Dr. Hopkinson's method of testing the magnetic qualities of iron he had a large massive block of soft iron of a rectangular shape with a rectangular hole slotted out, very much like Mr. Kapp's block, only more massive, and the test-pieces to be examined were two bars that met in the middle. It occurred to him in going through Dr. Hopkinson's researches that the effect that he sought to measure by pulling the two test-pieces apart, and measuring the flow of magnetic lines from one to the other by the little exploring coil pulled out sideways, might quite as well be measured, for commercial purposes, by the mere pull of one test-piece on the other. And having got as far as that, measuring the pull of one test-piece on the other, he said to himself, "Why should I take the trouble to make two test-pieces when exactly the same result can be obtained by having one piece and having the contact piece against the yoke?" He did not adopt that method without investigating it to see if it made very much difference. He took two test pieces and let one stick up against the yoke at one end and the other against the second test-piece in the middle of the coil, and then tugged at the test piece. Sometimes the iron separated at one end, sometimes in the middle; so there was not much difference in the two attractions which overcame the magnetic lines. So the simpler method, which he finally adopted, was quite adequate for the purpose. He would further say, about Mr. Kapp's second instrument, that he congratulated him upon having given them such an excellent instrument for measuring the magnetic properties of sheet iron. He thought the same criticism might be passed upon this instrument as upon the other. If the cross-section of the instrument could be enlarged very much indeed he thought it would simplify matters, especially as the hysteresis question came in to cause further complication. He was engaged in research on the behaviour of masses of iron such as were used in the first of Mr. Kapp's instruments, for the purposes of serving as yokes, yokes having no magnetic resistance, and he had arrived at a most interesting point of view, viz., that a large sheet of iron, so large as to be negligibly different from an infinite sheet, not less than 10 mm. thick, acted towards all things that might be placed in front of it as a magnetic mirror, giving, however, only negative images, and not positive mages. Suppose A (Fig. 1) to be a large sheet of good soft iron; then let there be a coil, B, placed anywhere on one side of it, say a hollow bobbin with some wires wound upon it, the current circulating round that coil had a certain magnetising effect through the coil. If no sheet of iron were there the magnetic forces round the coil, through the interior of it



and outside, would have certain values. Put the sheet there, and the effect was precisely the same as if the sheet were absent, and the coil were double the length, that is, if the coil and its image, B_1, were both at work. A little exploring coil placed hard up against the iron showed that the action of the iron was simply to double the action of this magnetising coil, and not only when hard up against the iron, but in any other position. Now, suppose a sheet of iron in that way at one end of a coil, and a second sheet at the other end. Then they had the same problem optically as if they put a candle between two mirrors, producing an endless row of candles; they got an endless row of coils. The effect of placing two large sheets of soft iron at both ends of a coil was practically to make the coil endless; in fact, they arrived at the conclusion that the ampere-turns on this coil, multiplied by 4π divided by 10 and divided by the length in centimetres, was a true expression for the intensity of magnetic force right down that line, as it was down an infinitely long solenoid. One thing he would like to suggest to Mr. Kapp, whether he could not suggest to them some way of getting at the magnetic properties of iron not in a rod or sheet, but in a block—a cubic yard, say. It ought to be possible. Let there be a thin strip of ebonite; drill in that two round holes, lay in those round holes two small coils, the one to receive a current, the other to give



a current to a galvanometer, a sort of transformer with no coil at all. Lay this on a block of iron and apply a magnetising coil. Some lines would come up through the hole, depending upon the goodness of the iron below. A complete magnetic circuit might be made by another block of iron on the top. Then they had the permeability, the magnetic reluctance between the two blocks, and a small air-gap between the two blocks. In that way they might have a method of measuring the permeability of iron in the mass.

Mr. STEELE: With regard to the permeameter, just one precaution should be taken in making out a sample bar. If, in the case of cast-iron or steel, a small sample was taken, sufficiently large, or turned to the required diameter, the results obtained on testing the sample in the instrument might prove considerably worse than the results obtained in actually testing the dynamo. This was due to the fact that the skin had not all been turned away. This took some time, and, as Prof. Hughes had remarked, an error might be made unless the end of the sample was placed properly against the plunger, and was placed in the right position. This difficulty of facing the ends might be got rid of by using a small cap carefully faced at the end, this to be used for every sample. The three-voltmeter method was used for testing the loss of the iron. The tests were accurate enough, but the results required laborious working out. The wattmeter now used required much less work, and yielded equally accurate results, quite consistent with the old three-voltmeter tests. The facility in making tests of this sort had helped in a large degree to reduce the losses in the transformer, and the efficiencies obtained now were quite high as compared with the efficiencies of a year or eighteen months ago.

The loss was only 0·95 per cent. of full-load, and the full-load efficiency was 97·4, which he thought, they would agree was fairly high.

Kapp Transformer—100 frequency.

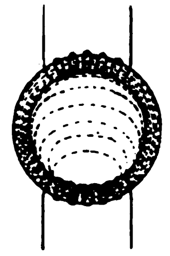
20	0·93	97·4

Very often an actual fault in the transformer might be due to the partial short-circuiting of the primary or secondary coils. This would increase the magnetising current greatly, and also increase the watts. It was difficult at times to localise the fault. The method they had found to answer was to suspend a rod of iron horizontally, and move it in the direction of the leakage lines of the transformer. If any of the turns were short-circuited, magnetic leakage would be produced, and this piece of iron would suddenly dip and be attracted towards the place where the coil was short-circuited. The fault thus localised, the difficulty might be to find out whether it was in the primary or secondary coils. This could be

Digitized by Google

met by sending a current through each coil and repeating the experiment, when the position of the fault would at once be shown.

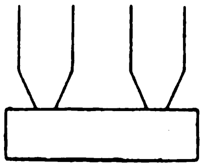
* Dr. FLEMING was not sure that it was always certain that unless you tested the iron in the form in which it was going to be used you were able, from experiments on small samples, to deduce what were the total losses in the iron. Laminating below the thickness of 10 or 13 mils. might eliminate eddy currents in certain iron masses; but it did not follow when worked up into a transformer, eddy currents would not be produced. The form which it might have might be such as to produce eddy currents circulating in the plane of the strip. Take one form which did exist—though it was the worst possible arrangement—and imagine a very thin strip of iron an inch or two wide wound up edgeways; now put on a couple



of coils, primary or secondary, and they could predetermine the loss in the iron at no load. Nevertheless, when working the transformer at full load there would be considerable magnetic leakage, and those lines of induction would sweep backwards and forwards perpendicularly to the iron, and that would create eddy currents in the plate however thin it might be, and that would produce eddy-current loss. There was an extra loss which might ensue if the transformer was not dry that in some cases was very marked. He thought in all cases the cores of transformers ought to be baked to a fairly high temperature before being wound, and then, of course, care must be taken that they were not in any way spoiled before they were tested. There was another thing which it was also important to bear in mind, although one must hesitate about speaking too confidently, and that was that the loss in the iron seemed to depend upon the form of the E.M.F. curve. He had recently had some correspondence with Mr. Blathy, in which that question had been raised. Mr. Blathy tried the experiment of taking the same transformer and testing it on a machine which gave a true sine E.M.F. curve, and then trying it on another machine in which it was known that the form of the E.M.F. curve was very different from the simple sine curve, and the result was that the transformer when tested on the simple sine curve gave a markedly higher loss than when tested on the other. Manufacturers found some difficulty in repeating the quality of their iron. They would specify for a particular quality, and make up certain transformers with it, which came up to the specification or standard; they repeated that order, and were unable to get it, and had to confess themselves disappointed in their iron. Nothing would be more practically important than to ascertain whether it was possible to get rid of hysteresis altogether, and whether it was not a thing which might some day be abolished. The question was partly an electrical one, partly a chemical one, and partly a mechanical one.

* Mr. SPARKS wished to ask very much the same question. When Mr. Kapp tested his sample bar, did he find the results obtained in practice anything like those obtained during the experiment? Because the sample had to go through the operation of being drawn out, it was forged to a greater extent than an ordinary magnet block, and there was also a chance of its being better annealed. The working up in a lathe would affect the sample differently to a large block, it being machined in another way. Under those circumstances one would imagine the results obtained would differ very greatly in the experimental bar from those which would be obtained when the iron was made up in the form of the field of a dynamo. He had made a great many experiments on samples, but the great difficulty seemed to be that even in testing one sheet there was an enormous difference between the results of different parts of the sheet.

Prof. PERRY thought Prof. Thompson's method was not a good one for testing iron in block. It was air resistance which was tested, and there was no saturation and no permeability at all. With regard to a remark made by Prof. Hughes as to the reason why bad fitting produced such very evil results, it might not be known to those who had not to make to sell, that if you wanted great lifting power in a permanent magnet all you had to do was to have the area of contact between copper and magnet ridiculously small. On every square centimetre of area the attraction was proportional to the square of induction. For only a small area there was far greater intensity of induction. If they diminished the area, having the

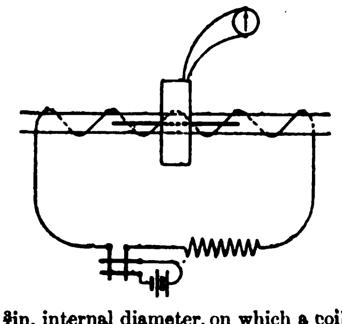


same total amount of induction, they would have an exceedingly increased force. In connection with this subject, some of them may have been astonished at some results of his published some time ago on the permanent magnet induction that could be obtained in steel. He believed he gave results three times as great as anybody else had given. They could get an enormous induction if they properly shaped their magnet.

Mr. MORDEY congratulated Mr. Kapp on the practical style of his instruments. He would ask him whether he had experimented with testing-bars on the effect of time in changing the carrying power of the bars. Another point which was of interest to dynamo builders was the fact that the bars were not true samples of bulk—small test bars. One often found that iron differed a great deal in the piece. He had seen a dynamo in which the armature always pulled to one side; there seemed to be no reason for it, but on investigation it was found that there was such a difference in the quality of the iron of one end of the bars and that of the other, that an actual pull was exerted in one direction. He had had a great deal of trouble on account of the inability of iron manufacturers to supply iron of anything like even quality, and the statement of Mr. Kapp, that iron makers are now offering iron that will conform to definite specification as to watts per pound, was probably the result of the efforts of the Brush Company to obtain iron in that way. As a matter of fact, they ordered and obtained their iron to a specification of that sort, and as the specification was public property he saw no reason why he should not mention the terms of it. The standard taken was 2,500 lines per centimetre, and the loss at 100 periods was 0·38 of a watt per lb.; that was a standard very easily worked to, and the quality was exceeded to the extent of iron being obtained of 0·25 and 0·28 of a watt per lb. On the other hand, it varied 60 per cent. above that standard frequently, even out of the same case of iron. That was a very awkward circumstance for all of them. The interests of all were identical in this matter, and they should all do everything they could to encourage ironmakers to face this subject, and endeavour to ascertain the reason why iron sheets varied so enormously. They were facing it after a fashion, but the iron people did not understand electrical and magnetic quantities at all; they looked upon the thing as a kind of sacred mystery, and shrugged their shoulders when asked to give iron of definite quality—or had done so until lately. As far as his experience went, chemical analysis was absolutely no guide whatever to the quality of the iron. That would seem to indicate that it was a physical question, a question of condition, and not of chemical composition. He did not know what arrangement was made in connection with this instrument to show how the power factor varied. It was an extremely curious thing, this variation of the power factor in connection with iron under alternating currents. The power factor might vary all the way from 0·6 to 0·9, but the hysteresis might be practically the same. The power factor might vary very considerably; as a rule it did not vary more than 6 or 7 per cent., but it might vary through those limits, and that meant that any test taken of current was valueless. It was extremely interesting to endeavour to find out what was the reason of this variation of the power factor of transformers. As far as he knew there was no information at their service on the point. At one time he thought it had to do with the electrical resistance of the iron, but from some tests he had made he did not find any connection there. It was a very important effect, because it affected central station engineers in the outgoing current in the daytime. He was rather surprised to hear that he found very little difficulty with the contacts in the testing instrument. He (the speaker) had found a great deal of difficulty with the contacts, and in the specification to which he had alluded they made it a rule to make that specification apply to the particular form in which they used the iron. The iron had to be used in certain transformers of certain types, and therefore the test was made applicable to the particular type of stamping. They found that in varying the contacts even slightly they could not get anything like the same results.

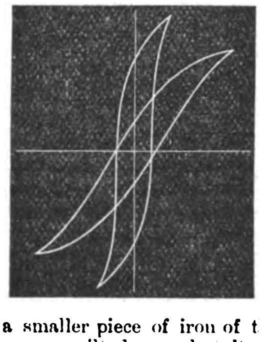
Mr. RAVENSHAW thought the importance of testing armature iron was as great as that of testing transformer iron. The losses were larger in large dynamos very often than in small ones. Iron varied very much indeed, and cases had lately come under his notice where it was desired to test iron, and difficulty was found in getting it done rapidly; a simple form of apparatus like that would have been of the greatest value for the purpose. A case had come under his notice where the hysteresis losses in iron were exactly twice in bulk what they were in the samples.

* The PRESIDENT (Mr. Alexander Siemens) remarked that Mr. Kapp said in his Paper that the method devised by Dr. Hopkinson and Prof. Ewing gave most accurate results, but the very perfection of those methods formed a drawback to their adoption in engineering works where highly-trained experimenters could not be found; and then in another place he said the sample consisted of a bar accurately turned and faced. Judging from the remarks of Prof. Hughes and Mr. Mordey, Mr. Kapp had simply shifted the difficulty from being an electrical one into a mechanical one, because to produce those beautifully turned bars required a long time and a good deal of mechanical skill. He wished to show them the way in which they tested the magnetic qualities of iron at Woolwich. They would at once see that it was a very much simpler and safer method than Mr. Kapp's. The apparatus was based upon that of Prof. Ewing, and consisted of a brass



tube 3ft. long and ⅜in. internal diameter, on which a coil was wound which was in connection with a rheostat, a double key, with a battery which gave about 10 volts, and there was an exploring coil on the first coil which was

connected with an ordinary galvanometer. Now what was done was to plot out the hysteresis curves of the various sorts of iron. When a piece of iron was put in care was taken that it was not as long as the brass tube. Then a current was sent through the coil, varied by inserting more or less resistance by the help of the rheostat, and the kicks which the galvanometer gave each time the resistance was altered were plotted down. The double-current key gave them the opportunity of reversing, so that they could get the complete curve. The area of the hysteresis at once gave the



quality of the iron. If a smaller piece of iron of the same quality were used, the hysteresis lozenge was tilted over, but it remained of the same area. There was no fitting in this whatever. They need not make the samples of the same length to compare with them, but merely cut off a strip of iron from the block they wanted to test, put it in the brass tube, and make the curve, which one man could do in a quarter of an hour, and they knew at once quite accurately what quality of iron was before them.

Mr. KAPP, in replying, said Prof. Hughes had really struck the keynote of all the important objections to the instrument, and that was the difficulty of getting the surface so true that they could rely upon its contact. They must not forget that this instrument was not for testing inductions of 2,000 or 3,000, in which case the question of surface would be of more importance, but for testing inductions of 10,000, when it did not matter if the surface did not lie on quite flat. He had taken the trouble to spoil one of the samples for the purpose of ascertaining that. He was a little disappointed that Prof. Thompson left off at the most interesting part of his remarks. Had he succeeded in making the corrections in his permeator smaller than in his (the speaker's)? But the difficulty was that it must have fairly good contact where it went through the top yoke. His (Mr. Kapp's) object in pulling away the plunger was to keep the sample tight and confine his corrections to one plunger and the same piece in every experiment. It was important, of course, that there should be a definite quantity of iron under test. Supposing they had a definite quality of sample. Let them make the enormously big bottom yoke. Would Prof. Thompson, or anybody else, tell him the length of the sample he was testing? It was utterly impossible. In Fig. 3 they had two curves, both taken by the testing machine. The top curve had an average of about five different suppliers' iron—not five samples, but a lot supplied from five different sources. The bottom one was supplied by a merchant who kept his maker very secret; it was very excellent, but he had never been able to reproduce it. It was interesting to find Mr. Mordey's specification tallying so well with his average; his was about 0·35 and Mr. Mordey's 0·38. As to the power factor, he had made no experiments.

THE LIVERPOOL OVERHEAD RAILWAY.*

BY J. H. GREATHEAD AND F. FOX, M.M.INST.C.E.

The Paper began with a history of the undertaking, which was the practical solution of a difficulty first experienced 40 years ago, namely, the provision of better communication for passengers along the frontage (now extending to 6½ miles) of the Liverpool Docks. The elevated railways in New York had been highly successful in meeting the wants of the travelling public, but were attended by several inconveniences. There were no parapets and no floors, the sleepers being placed directly on the top flanges of the girders. The result was that, as the railways were worked by steam locomotives, cinders, oil and water dropped into the street; fine shavings from the rails and tires fell on the foot-passengers, and in one case, at least, a locomotive had fallen bodily into the street. Mr. A. G. Lyster, who had minutely studied the New York system and reported thereon to the Liverpool Corporation, had expressed himself in favour of an overhead electrical railway, and after some delay an Act was obtained in 1882 by the Mersey Dock Board for the construction of a double line of 4ft. 8½in. gauge. The estimate for this, fully equipped and worked by electricity, was £466,000. The structure was intended to consist of plate girders, with overhanging continuous footways having parapets of iron lattice-work, with the rails laid upon greenheart planking; the whole being supported by columns of partial lattice-work placed in the normal structure, one on each side of the lines of dock-railway. Owing to the fact that many influential members of the Dock Board were unwilling to embark upon railway management, the undertaking was in 1887 leased to the present Liverpool Overhead Railway Company, by which the line was constructed.

The length of railway at present worked was 5 miles, but would ultimately be 6½ miles. In the structure decided upon the columns were placed vertically under the ends of the main girders, about 22ft. apart from centre to centre, allowing sufficient width for two lines of standard gauge with the usual 6ft. way, and admitting the use of carriages 8ft. 6in. wide. Local circumstances in many cases did not, however, admit of the columns being placed immediately under the main girders, and the latter were then carried upon cross-girders outside the line of columns. For considerable lengths, also, the columns had to be embedded in the boundary and warehouse walls. Owing to the presence of the dock lines below, cross-bracing of the piers in the usual way was impossible, and it was necessary to give to the columns and to the shallow cross-bracing connecting them at the top sufficient strength and rigidity to resist the lateral stresses due to wind-pressure, and, on curves, to the centrifugal force resulting from the motion of the trains.

In carrying out the works no special difficulties arose in connection with the foundations of the piers. In places where rock was not reached, masses of concrete were deposited of sufficient extent to insure the maximum load on the base not exceeding one ton per square foot. In excavating for the foundations the sill of the first dock made in Liverpool was discovered, and several lengths of old water pipes, consisting of trunks of trees bored out and fitted together, were brought to light. Owing to the railway being placed immediately over the dock-lines, the latter were in many cases diverted, straightened and improved. The columns supporting the viaduct consisted of two steel channel bars riveted to two steel plates, forming a box column with all the rivet-heads outside. These columns were grouted into cast-iron sockets bedded in and bolted through the blocks of concrete. Cast-iron bumpers filled with cement-concrete protected the columns from injury from passing waggons. The normal span was 50ft., but longer spans up to 98ft. and shorter ones of about 30ft. were required in some cases. Up to 75ft. span, the height of the girders above the rail level did not exceed the platform height, and plate-girders were used. In longer spans bowstring-girders were used. Between the girders was fixed Hobson's arched-plate flooring, consisting of $\frac{5}{16}$-in. plates bent to a radius of 12-in., with a flat surface 6in. wide on the top, riveted to intervening T-bars, and made water-tight by asphalt run in the V-channels between the arches. The structure was so designed that the spans could be put together and riveted up with floor complete at one or both ends of the railway, and be then transported over the completed portion of the structure to be placed in position. A special form of erecting-machine was provided, consisting of two lattice-girders standing upon legs resting on the ground at the front end, and at the hinder end upon a carriage running on rails on the viaduct. These girders were placed at such an altitude as to allow the trolley carrying the succeeding span to be rolled along underneath them. On these lattice-girders were placed two travelling cranes, so arranged as to lay hold of the spans on arrival, run them forward, and deposit them in their permanent position upon the columns which had been erected in advance. The average time occupied by this operation was one hour per span.

In the course of the work several opening bridges had to be provided which were described and illustrated in the Paper, as were also the stations, permanent-way, and rolling-stock.

The total quantity of iron and steel in the structure was about 22,000 tons. The total capital cost, including equipment and all other charges, had been £550,000, or about £90,000 per mile of railway. The line was formally opened by the Marquis of Salisbury on February 4, 1893, and was opened for traffic on March 6th following. The electrical system of working was completely successful, a five-minute service of trains being maintained with perfect regularity and without mishap of any kind. On the last August Bank Holiday about 40,000 passengers were carried in the space of eight hours.

* Abstract of a Paper read before the Institution of Civil Engineers, Tuesday, February 27th.

CORRESPONDENCE.

THE GRIFFIN ENGINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Seeing a letter under the heading of "Double-Acting Gas Engines" in your issue of February 16th, in which reference is made to the "*obsolete Griffin engine*," we shall feel much obliged to you if you will kindly point out in an early edition of your paper that the "Griffin" *gas* engine is an entirely different machine to the "Griffin" *oil* or *hydro-carbon* engine, for which we hold sole licence to manufacture in this country, and which is now being placed upon the market, and giving unqualified satisfaction.

We draw your attention to this point because, perhaps, in the hurry of reading a letter of this character, the two engines might be somewhat confused.

In respect to Mr. Griffin's *gas* engine, we have no doubt that he will take up this matter himself in due course.

Thanking you in anticipation of your kind attention to above.—Yours, &c., SAMUELSON AND CO. (LIMITED).

Britannia Works, Banbury, England,
February 23rd, 1894.

LEGAL INTELLIGENCE.

M'Carthy v. Electric Construction Company (Limited).

This was an action in the Lord Mayor's Court, before the Recorder (Sir Charles Hall, Q.C., M.P.) and a special jury. It was a claim by the plaintiff to recover the sum of £2,600, being the proceeds of the sale of 605 shares in the defendant Company, by whom the plaintiff was formerly employed as clerk and bookkeeper.

In opening the plaintiff's case, Mr. PYKE, Q.C., stated that the proceeds of the shares in question had been received by the defendant Corporation. The Electric Construction Corporation was founded, promoted, and formed in the year 1889, at the instance of the Building Society Securities Corporation, at the head of which was Mr. Jabez Spencer Balfour. Mr. J. S. Balfour was a Director, and the shareholders included Capt. Dibley, Henry Granville Wright, Hobbs, and Newman, all of whom became shareholders in the Electric Construction Corporation, and some of whom were Directors of both companies. In 1889 there were allotted to Capt. Dibley 1,712 £10 shares in the Corporation which purported to be fully paid up. That being so in 1891 Dibley transferred 1,500 of these shares to a Mr. Tarver, who was, in fact, the Building Securities Company, of which he was the secretary, for the large consideration of £10. Shortly before the crash of the Balfour companies came, the shares which Dibley had transferred to Tarver were re-transferred to the defendant Company in the names of Sir Daniel Cooper and Mr. A. Courtney for the consideration of 5s. On October 18th, after the collapse of the Balfour companies, 500 of these shares were transferred to a Mr. Brownham, a clerk in the firm of Messrs. Bonsver, Wright and Company, of which the well-known Henry Granville Wright was a partner. Those shares were sold within a few weeks by the defendant Corporation for the sum of £2,234. 7s. 6d. The sum was paid by a cheque drawn to M'Carthy, or bearer, and was paid by the Corporation into their bank. The plaintiff's case was that, having taken the risk attaching to those shares, he was entitled to the sum which they realised. The contention of the defendants was that the shares were put into the hands of the plaintiff for sale as trustee of the Corporation, but plaintiff's counsel contended that this was no defence in law, as the Corporation had no power whatever to deal in its own shares. The plaintiff, as the holder of the certificate, was the legal owner of the shares, and entitled to the proceeds of the shares. On November 14th 105 more shares were transferred to Mr. M'Carthy in the same way, and the proceeds of those shares, amounting to £414, were kept by the Corporation, they having been sold, and these sums together made up the plaintiff's claim.

After the plaintiff had given his evidence, it was submitted on behalf of the defendants that there was no case to go to the jury, and, after hearing the address of counsel, the jury intimated that they had made up their minds, and they returned a verdict for the defendants.

The RECORDER said that he was not in the habit of making remarks on the verdicts of juries, but he must say that in this case he thought it only fair that the defendants' counsel should have been allowed to give explanations, and he also thought that there been an unjustifiable use of names in the case.

Carboid Oilless Bearing Company (Limited) v. Planet Electrical Engineering Company (Limited).

This case was tried on Monday in the Westminster County Court (London), before Judge Lumley-Smith. It was an action brought to recover £12. 17s. 4d. for electric fuses supplied.

Mr. CANTLEY, for the plaintiffs, called Mr. RUDKIN, Manager to the plaintiff Company, who said that Mr. Scott called from the defendants in August, 1892, to ask the price of patent fuses. On the 12th he again called, and in the end plaintiffs had an order for 584 fuses. Witness explained to Mr. Scott that the eyelet holes were rather large, and he said they must be the size ordered, as they had their terminal fitttings made. The order was completed by September 6th, and after invoices had been sent plaintiffs took legal proceedings. The fuses were made of tinfoil and mica fixed together with two brass studs and would carry 300 amperes.

Mr. MADDISON, for the defendants, said plaintiffs had not supplied what was ordered. The fuses were for the Railway Clearing House, and were to carry 300 amperes, and they went before 150 was carried. They were tried in the Railway Clearing House, a place where light was absolutely necessary, and they went out. Plaintiffs were complained to, and only answered to the effect that if they were not paid they would go to law.

The JUDGE: Do you say they were useless for low pressure?

Mr. MADDISON: Yes.

Mr. SCOTT, secretary of the defendant Company, said about August 9, 1892, his firm got the order for the fuses. He went to the plaintiffs' place at Westminster, had an interview with Mr. Rudkin, and on the 12th took the order and specification. The fuses were supplied. Plaintiffs called for payment, and witness pointed out that the goods were not up to specification.

Defendant Company's ENGINEER said he went to the Clearing House. The fuses he found got very hot. They would not carry 150 amperes. He had the lights turned on in batches.

The JUDGE: Are the fuses stamped with the amount they are supposed to carry?

WITNESS: Yes; some of the fuses went near endangering the installation. Defendants only objected to the 300-ampere fuses. The Clearing House engineer objected to the others. He believed there was an arbitration with the Clearing House about the lighting. They were still using the low-pressure fuses at the Clearing House. They were there on sufferance. The larger the tinfoil the more would the fuse carry. It all depended on the sectional area of the tinfoil. There was a counter claim for £20, and the witness said that this was made up of £7. 16s., his and the manager's expenses, and new fuses and expenses, £13. 4s.

Mr. LANGDON, engineer to the Railway Clearing House, said he complained to the defendants about the fuses. He corroborated the defendants' engineer as to the failure of the fuses.

The plaintiffs called Mr. HEDGES, who said he was the inventor of the fuses. There was no fault with the fuses supplied by the plaintiffs. Similar fuses were supplied to the Midland Railway. All but five of his fuses he had seen in use at the Railway Clearing House.

The Jury found for the plaintiffs both for the amount claimed and on the counterclaim.

His Honour gave judgment accordingly.

Town Council Prosecution.

At Windsor, Alfred Edward Farrow, engineer to Messrs. Roger Dawson and Co., was summoned for having broken up the paving and roadway in High-street on January 2nd, without having first obtained permission to do so. The proceedings were taken under Section 149 of the Public Health Act, 1875.

Mr. G. H. Long, town clerk, prosecuted. The defendant admitted the offence, regarding which evidence was given by the borough surveyor and the road foreman to the effect that the roadway and paving in High-street were broken up on January 2nd, during the night, for the purpose of laying electric wire. A man in the employ of the defendant said he opened the road by defendant's orders. The Mayor said that if the defendant had applied for permission to break up the road he did not think it would have been refused. The Chairman said they had taken a very lenient view of the case; it was not to be tolerated for men to come into the town and set the authority at defiance. A fine of £2 was imposed, and £1 costs and 3d. for each square foot of roadway disturbed, or £3. 10s. in all.

The Storage of India-Rubber Solution.

A case of considerable interest to the india-rubber and cycle trades was decided at the Birmingham Police Court on Thursday last week. The India-Rubber, Gutta-Percha and Telegraph Works Company (Limited) was summoned, under the Petroleum Act of 1874, for storing without a licence, at their depot in Albert-square, Birmingham, 1,277lb. of india-rubber solution, which contained 84·8 per cent. of naphtha. It was contended that this commodity came within the meaning of the Act, and that a licence was required for its storage. It gave off inflammable vapour at 54°F., instead of at 73°F.

Mr. A. YOUNG, for the defendant Company, contended that the Act was never intended to apply to petroleum in combination with an article of commerce, but merely to petroleum and other oils specified, pure and simple.

After hearing the evidence, the Bench fined the defendants the nominal penalty of 40s. and costs, intimating that in future similar offences would be more heavily dealt with. They, however, expressed the hope that the solution, which was valued at £100, would not be forfeited if defendants made the required provision for its storage.

McGeagh v. Elmore's Foreign and Colonial Patent Copper Depositing Company (Limited).

This case which, as reported in our last issue, was adjourned, was disposed of in the City of London Court by Mr. Commissioner Kerr. Judgment was given for the plaintiff, Mr. McGeagh having during the adjournment (it is stated) agreed to go into the scheme of reorganisation of the French Company.

In re Adamson.

In the Bankruptcy Court last week Mr. Justice Vaughan Williams heard a motion *in re* Adamson, a bankrupt, in which a Mr. Pembroke was a creditor for £150, and his proof, lodged in May, 1892, stated that he had no security for his debt "except 50 shares in the International Cable Company, which are of no value." That Company was then in liquidation, and it was not anticipated that there would ever be any value in the shares. A year afterwards, however, certain litigation in which the Company were engaged was settled in their interest, and the shares became of a certain value. The trustees now applied to have the shares handed over for the general purposes of Adamson's estate, on the ground that Mr. Pembroke's proof declaring the value of the shares to be nil amounted to a surrender of them.

It was contended for Mr. Pembroke that he might, under Rule 13, at any time amend his proof on showing that his original valuation of the security was based on a mistaken estimate.

Mr. Justice VAUGHAN WILLIAMS held that the trustee might, immediately on Mr. Pembroke's first proof being made, have demanded the shares, but as he had not done so, and Mr. Pembroke having now filed an amended proof, the shares must remain in his (Pembroke's) hands as a security for his debt. Rule accordingly.

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

Our readers are reminded that the 1894 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This valuable book contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.) A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). prospectus on application to the Publisher.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

TENDERS INVITED.—It will be seen by our advertisement columns that the Corporation of Royal Leamington Spa invite tenders for the erection of five short lines of telephone wires, and for the supply and fitting up of six sets of telephone apparatus. Tenders must be sent in to Mr. H. Consett Passman, the town clerk, before noon on the 12th instant.

———— The Corporation of the Borough of Brighton invite tenders for the supplying and laying of armoured and lead-covered cables, of which specifications can be obtained on application at the office of Mr. Francis J. Tillstone, the town clerk, Town Hall, Brighton, to whom tenders have to be sent in before 10 a.m. on Monday, the 12th inst. Some further particulars appear in our advertisement columns.

———— The Technical School Committee of the Bury Corporation invite tenders for electric light fittings, which must be in by March 10th.

TENDERS RECEIVED.—The Directors of the Northern Co-operative Company have received tenders for the installation of the electric light throughout their large premises at Aberdeen, and have appointed a committee to classify and arrange the offers.

TENDERS ACCEPTED.—The Hull Corporation have accepted the tender of Messrs. W. H. Allen and Co., for a surface condensing plant at £759; and from Earle's Shipbuilding and Engineering Company for supplying and laying 400ft. of 10in. cast-iron suction and delivery pipes, for £284.

———— The Directors of the Yorkshire House-to-House Electricity Company (Limited) have let the contracts for the extension of their electricity works as follows: For buildings, Messrs. William Nicholson and Son; for plant, Messrs. Hick, Hargreaves and Co. (Limited), and Messrs. John Fowler and Co. (Leeds), Limited.

———— The Norwich Town Council have accepted the tender of Messrs. A. Pank and Co., of Norwich, to provide and fix fittings for lighting the Guildhall and municipal and sanitary offices by electricity for the sum of £290. 17s.

PLANT FOR SALE.—Messrs. Wheatley Kirk, Price and Goulty advertise a quantity of second-hand electric lighting and other plant for sale, including dynamos, boilers, engines, lathes, &c. Further particulars are given in our advertisement columns.

BANKRUPTCY.—The discharge of Thomas Fletcher, electrician, of 188, Broadhurst-gardens, West Hampstead, has been suspended until a dividend of not less than 10s. in the £ has been paid. The bankrupt is to pay the Official Receiver £120 a year, in monthly instalments, with liberty after two years to apply for a modification of the terms.

DISSOLUTION OF PARTNERSHIP.—Mr. John A. Edmondson, of the Globe Electrical Works, Bradford, and of Leeds and Huddersfield, notifies that the partnership hitherto subsisting between Harris Ullathorne and John Alfred Edmondson has been dissolved, as from February 24th, and that Mr. J. A. Edmondson will in future carry on the business alone, in his own name, at the same addresses.

———— We are informed by Mr. Harris Ullathorne that he has entered into partnership with Mr. Arnold Hartley, and that they will in future carry on business as electrical engineers at the Crown Electrical Works, 19A, Charles-street, Bradford.

———— Notice is also given that the partnership hitherto subsisting between Mr. Sheard Charlesworth and Mr. Joseph Platt Hall at Richmond Hill Ironworks, Oldham, under the style of Charlesworth, Hall and Co., was dissolved on February 26th, Mr. Hall having purchased Mr. Charlesworth's interests in the property, and assets of the firm. Mr. Hall continues the business under the style of J. P. Hall and Co.

LIQUIDATIONS.—At a meeting held on February 12th of Fowler's Engineering Company (Limited) it was resolved to wind up the Company voluntarily, and Mr. P. Holman, 11, Queen Victoria-street, E.C., was appointed liquidator.

———— It was resolved at a meeting of the Platinum Plating Company (Limited) held on February 23rd, at 27, Clement's-lane, E.C., to voluntarily wind up the Company, and Capt. R. W. Shackel, Elmhurst, Mitcham Common, was appointed liquidator.

———— A meeting of the Freedman Battery Company (Ltd.) will be held at 66, Berners-street, W., on March 31st, at 3 p.m., to receive an account of the winding up.

TRADE ARBITRATION BOARDS.—It is announced that the French Minister of Industry and Commerce has communicated with prominent English labour leaders, asking for particulars *re* trade arbitration boards, as the French Government are about to legislate in this direction.

MESSRS. BENNETT AND DRUCE.—This firm have received instructions from Messrs. Frisby, Dyke and Co., of Liverpool, to instal the electric light throughout their extensive premises. The plant will consist of a special high-speed Otto gas engine, a compound-wound dynamo, and about 250 incandescents distributed over the shop and premises, from which gas is to be entirely excluded.

ELECTRIC CRANES, &C.—Messrs. J. G. Statter and Co. have recently received an order from the South-Western Railway Company of Russia for the supply of three electric cranes and the necessary plant for generating station for the harbour at Odessa. The cranes are to be similar to those supplied to the Southampton Harbour Board and to the London and India Docks Joint Committee.

MESSRS. MILLER AND WOODS.—This firm send us an illustrated price-list and catalogue of electrical accessories, including a transformer for heating medical cauteries, a sub-divided transformer for obtaining a higher or lower pressure than the normal from alternating-current street mains, a pressure reducer for continuous current, and a specially-designed focussing lamp.

BAMBOO FITTINGS.—Mr. W. Bowker, of Messrs. Bowker Bros., Preston, has had on show in London a number of examples of bamboo worked into various artistic and plain designs for electric light fittings. The examples shown included brackets, three and six-light electroliers, &c. It is claimed that bamboo lends itself to easy treatment for almost any design for such fittings as are required in either temporary or permanent lighting installations. The specimens of Messrs. Bowker Brothers' work shown were remarkable for their lightness and portability, and it was stated that the fittings can be supplied at a much cheaper rate than metal fittings; that they can be made to be taken to pieces readily, and are easily packed. For temporary installations or for festive gatherings very artistic effects can be produced in a comparatively short time at trifling expense. The bamboo can be easily painted, bronzed, gilded, or varnished. It is stated that in the neighbourhood of Preston, where the firm's works are situate, many of the principal hotels and several private houses have been installed throughout with these fittings. It is especially pointed out that the fire insurance companies have passed the fittings, which will, of course, neither tarnish nor corrode, and are easily cleaned. They can be readily adapted to surrounding decorations.

ABERDEEN.—Mrs. Stewart, the wife of the Lord Provost, on Tuesday night switched on the electric current to the ten electric lamps of about 2,000 c.p., which have been erected in Castle-street, Union-street, and St. Nicholas-street, Aberdeen.

ABERYSTWYTH.—The Town Council have received the proposal of the Bourne and Grant Electricity Supply Company (Limited) with reference to the lighting of the Marine front. The proposal

Digitized by Google

is to place 20 arc lamps along the Parade, and the Company offer to lay the mains free of charge on a lighting contract being agreed to for a term of years. A committee meeting of the whole Council was held yesterday, and a confirmatory meeting is to be held to-morrow.

ACTON (MIDDLESEX).—At the last meeting of the Local Board the Finance Committee reported that the surveyor had provided information concerning the probable cost of establishing a system of electric fire alarms and calls throughout the district, and the Committee had requested the surveyor to supplement these particulars with further information from the Willesden and Ealing districts. The Works Committee have made some alterations to the agreement regarding the electric lighting of the district, and have returned this to Mr. Medhurst for reconsideration. If the alterations are accepted the conditions of lease and schedule are, we understand, to be considered.

ASHFORD.—It has been arranged to light the grounds of the Trades and Inventions Exhibition, shortly to be held at Ashford, by the electric light, the contract for which has been placed with Mr. King, of Maidstone.

BOURNEMOUTH.—A question was asked at the Town Council meeting last week as to whether the time had not arrived when consideration should be given to the subject of lighting the borough by electricity. After some discussion the Council decided that they were not prepared to consider the question at present.

BRISTOL.—A public meeting of the inhabitants of St. George was held last week, at which it was unanimously decided to ask the Bristol Town Council to afford every possible facility to the promoters of the electric tramway scheme from Kingswood to St. George. It was announced that under the scheme the Tramways Company were prepared to spend between £2,000 and £3,000 in widening the main roads of the district. At the last meeting of the Bristol Corporation it was agreed to grant the Tramways Company the powers asked for to enable them to proceed with the construction of the electric tramways, which the Company estimate will entail expenditure amounting to about £50,000.

CHELSEA (LONDON).—At the meeting of the Vestry the Hall and Electric Lighting Committees reported that they had again considered the advisability of lighting the Town Hall by electricity, and had obtained thirteen estimates for wiring, &c., varying from £225 to £500. Before finally accepting any estimate, it will be necessary to arrange with an electrical engineer to superintend the work during its execution, at a fee of £26. 5s., or to inspect the installation, after completion, at a fee of £15. 15s. The Committee recommended that the Vestry undertake the work themselves, and that Mr. Morgan Williams, of Messrs. Morgan Williams and King, Victoria-street, London, S.W., be appointed to superintend the work. After some discussion, this proposal was agreed to.

CHURCH LIGHTING.—The church and churchyard of St. Mary-at-Hill, London, has for some time been closed. The church has now been fitted with the electric light, and was reopened by the Lord Mayor and Sheriffs in state last week. The installation has been carried out by Messrs. Smeeton and Page.

CROYDON.—At the meeting of the Corporation on Monday the General Purposes Committee presented their report, recommending that the Council proceed with the lighting of the compulsory area, under the Order already obtained, and that application be made to the Local Government Board for sanction for a loan of £25,000 for this purpose. In January of last year a recommendation of the Committee that the Council should carry out the lighting of the compulsory area at an estimated cost of £22,500 was referred back, and later the Committee again brought the recommendation forward with the amount of estimated expenditure fixed at £25,000. This was again referred back, and now again comes up as a recommendation from the Committee. Councillor Miller, in moving the adoption of the report, said that there was no question as to the demand for the electric light in Croydon, and obstacles should not be placed in the way of obtaining it. The Chairman of the Electric Lighting Company at Bradford had told him that, even supposing their electric lighting works were doubled, they would be unable to meet the demand for the light. With reference to the lighting of their new Town Hall at Croydon, this was estimated to cost £500 per annum, but he felt sure that in a short time the building would be lighted at 25 per cent. less than the sum which would have to be paid if gas was utilised. Mr. Preece's estimate for installing the light in the Town Hall was about £3,500, but he said that if the Corporation had the light from the central station it would only cost £1,500. The tradesmen of Croydon wanted the light, and surely, as the principal ratepayers, they deserved consideration. The proposal was strongly opposed by Councillor Martin, who in the course of his remarks stated that "even now the electric light was in an experimental stage," and that "they were asked to spend £25,000 on an experiment which might result in failure!" After a long discussion the motion was rejected by 22 to 19, and was again "referred back."

EDINBURGH.—The Lord Provost's Committee of the Town Council have recommended the Council to refuse their consent to the proposed agreement between Messrs. Dick, Kerr and Co. and the Edinburgh Street Tramways. The object of this agreement was to carry on, as far as possible, the tramways concern as one undertaking. Regarding Messrs. Dick, Kerr and Co.'s proposal to form a new organisation and to transfer to themselves the control and management of the tramways undertaking, the Committee decided to recommend that no action be taken in this matter.

FRIEDRICHSRUHE (GERMANY).—Prince Bismarck's castle has just been fitted up for the electric light by the Hamburg branch of the Elektrizitäts-Gesellschaft vormals Schuckert and Co. The power is derived from saw mills belonging to the Prince situated at a short distance from the castle.

HULL.—Mr. A. H. Gibbings, the Corporation electrical engineer, has presented his estimates for the coming year, amounting to £4,387, which includes £2,000 for additional capital, making a total capital outlay of £37,000. The Chairman of the Electric Lighting Committee expressed his satisfaction at the working of the electric lighting station for the past year. After paying working expenses and interest about £100 is left to the good. The Committee had every reason to feel confident, and there was no necessity to ask for assistance from the rates, as the income would quite meet the expenditure. For the nine months they had been working they had supplied 75,000 units, and the demand was still increasing. They were working as cheaply as any company in England.

ISLE OF MAN.—The Directors of the Isle of Man Tramway Company have submitted to the shareholders an offer made by the Douglas and Laxey Electric Tramway Company for the purchase of their undertaking for £38,000, and recommend the acceptance of the offer.

KEIGHLEY.—The Gas Committee have recommended the Town Council to give instructions for the necessary notice, and to make application to the Board of Trade for an electric lighting Provisional Order to supply electric current throughout the district. The proposal came before the Town Council at their last meeting, and was approved.

LIVERPOOL.—At a meeting of the members of the Junior Reform Club, the sub-committee elected to consider the question of electric lighting, recommended the adoption of a new system now in use in Paris, but which had not, their report stated, been tried in this country. The proposal was adopted. The estimated cost is about £1,000.

LLANDUDNO.—The Gas Committee of the Improvement Commissioners, who have been discussing whether the Commissioners' sanction should be given to the proposal of a projected electric lighting company in their application for a Provisional Order, have recommended that the Board sanction the scheme and consent to the company's application, satisfactory terms being first agreed upon between the Commissioners and the proposed company with respect to the sale to the Commissioners within a specified time of the undertaking. After discussing the Committee's proposals, the Commissioners have referred to a Committee of the whole Board and the promoters of the proposed company the question of electric lighting and water supply.

LONDON COUNTY COUNCIL.—At the meeting of the Council, on Tuesday last, the Highways Committee's report, recommending that the Victoria Embankment be lighted by electricity from the centre of the roadway, the work being carried out by the Works Committee, was postponed.

MANSION LIGHTING.—Sir Thomas Lucas has entrusted Messrs. Drake and Gorham with the work of electrically lighting his house at Kensington Palace-gardens, for which 370 lights will be required. The decorations are very elaborate, and the house is built in an exceptionally solid manner; all the more credit, therefore, will be due to the contractors when the work is satisfactorily completed. The existing fittings have been adapted for the electric light.

MOSS SIDE.—At the last meeting of the Local Board the minutes of the General Purposes Committee, concerning a draft licence authorising the Board to supply electricity within the Township, were referred back to the Chairman and the Clerk for further consideration in detail.

NEWARK.—A proposal has been before the Urban Sanitary Authority in regard to the lighting of the district by electricity. The authors of the proposal have, evidently, not secured the interest of the Mayor, who, at the last meeting, stated that "in London the electric light was produced at a loss." He thought that they would be ill-advised to permit a company to work at Newark, and proposed that the application which they had received be not granted, which proposal was carried.

OSSETT.—A meeting has been held of the Tradesmen's Association of Ossett and Horbury, in order that serious complaint might be made of the quality and price of gas supplied by the local gas company. The meeting was largely attended, and many sugges-

Digitized by Google

tions were made, one of which was that an effort should be made by the Ossett Corporation and the Horbury Local Board to acquire the gas works. A Mr. Fothergill stated that he himself had installed the electric light owing to the very bad gas supplied, and he was of the opinion that the Ossett Co-operative Society would shortly put in the electric light. He further stated that, unless the Corporation were prepared to apply for a Provisional Order a local company would take the matter up, and endeavour to supply the district with electric current. After a long discussion, in which the suggestion was made that the electric light should take the place of gas for public lighting, it was finally decided to wait on the gas company, and place the matter before the Directors for their consideration.

Peterborough.—The Corporation have deposited £50 with the Board of Trade on the understanding that this sum is to be forfeited if the electric light in the city is not completed within two years. The *Peterborough Express* is responsible for the statement that "only certified electrical engineers will be permitted to make the electrical connections."

Rochdale.—A successful installation of the electric light has been made at the new church of St. Andrew, Dearnley, near Rochdale. The work has been carried out by Mr. James Wilcock, of Littleborough, near Manchester, to the entire satisfaction of the Building Committee. A 4-h.p. Crossley gas-engine is included in the plant, which provides current for 60 incandescents.

St. Pancras (London).—At the meeting of the Vestry on Wednesday, the Electric Lighting Committee recommended that they be empowered to obtain the loan required for electric lighting purposes elsewhere than through the London County Council. The Committee's recommendation was approved. The reduction by the London County Council of the period of time for repayment asked for by the Vestry has given much dissatisfaction.

Staff Dinner.—The staff dinner of the National Telephone Company will be held this (Friday) evening at the Holborn Restaurant, under the presidency of Mr. W. E. L. Gaine, the General Manager.

Stoke Newington (London).—At a meeting of the Vestry complaint was made of the price charged by the Gas, Light and Coke Company for supplying the district with gas. It was pointed out that the only way to compete against this monopoly was to encourage the electric light. The neighbouring district of Hackney has obtained a Provisional Order, and members of the Vestry favoured a similar course being adopted by the Stoke Newington authorities.

Suicide.—Mr. George Edward Forrest, aged 70, who assisted his son, Mr. James Forrest, in his electrical engineering business at Great New-street, Fetter-lane, E.C., committed suicide last week by shooting himself with a revolver. At the inquest, a verdict of temporary insanity was returned.

Theatre Lighting.—The Chairman of the Empire Palace, Leicester-square, London, announced to the shareholders at their meeting on Wednesday that the electric light had been installed throughout the large building and outbuildings adjacent belonging to the Company.

Tynemouth.—The Borough Surveyor has reported to the Trade and Commerce Committee of the Town Council on the proposed electric lighting scheme. A sub-committee's report states that Messrs. C. A. Parsons and Co. were the only tenderers for the carrying out of such works as were necessary to retain the powers conferred by the Provisional Order; that the tender for laying mains in Saville and Howard-streets amounted to £1.355, dynamo and accessories £445, and for lighting the Town Hall buildings £162, or a total of £1,962 in all. The sub-committee recommended that application be made to the Local Government Board for sanction to borrow £2,000 to carry out the scheme, but that only £1,355 be at present expended for cables. After some discussion, this report was adopted.

Toxteth Park.—The Local Board have just issued a scale of charges for testing, which are as follows:—

		s.	d.
Insulation of main	Each test	5	0
Conductivity of main	„	7	0
Insulation of service lines	„	2	6
Conductivity of service lines	„	4	0
Efficiency of joints	„	3	6
Tests of instruments of undertakers, per instrument		1	0
Tests of electric lines of undertakers other than mains and service lines		2	6

Warehouse Lighting.—The extensive new premises of Messrs. R. Maule and Sons, in Princes-street, Edinburgh, have just been completed, and were opened for business last week. The building occupies the old site of the Scottish Liberal Club, facing the Caledonian Station, and forms one of the largest blocks of business premises in Edinburgh. The buildings are lighted throughout by the electric light, and the installation includes an electric lift, worked off the lighting dynamo, which is a Siemens' 200 ampere. The plant includes a 28-h.p. Crossley gas engine. Altogether there are 38 150-c.p., 5 100-c.p., 2 50-c.p., and 36 16-c.p. incandescents. The lift has been put in by the Otis Elevator Company.

Wolverhampton.—At a meeting of the Wolverhampton Victoria Hotel Company, at which the Mayor of Wolverhampton was present, he said that, as Chairman of the Lighting Committee of the Corporation, he looked with great favour on the electric lighting scheme. He had used the electric light in his own house and at his works for a long period, and he would not be without it if it cost four times the price of gas. There was no comparison between gas and the electric light, regarding which he had prepared certain figures which would shortly be issued in printed form. He believed that if the electric light were used with care, and without waste, it was not more expensive than gas. He strongly advised the Directors of the hotel to instal the electric light in their handsome building. With regard to the new theatre to be built on land adjacent to the hotel, that also should be installed with the electric light, and he hoped that this would be ultimately decided upon. The Chairman of the Company, Lieut.-Col. E. Pritchard, said that it was the intention of the Directors to introduce the electric light into the hotel, as they were fully agreed as to the advantages of that illuminant over gas.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. Chapman, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.

APPLICATIONS FOR PATENTS.

January 23, 1894.

1,491. J. B. Barton. London. Improvements in arc lamps. (W. Jandus, United States.)

1,495. W. L. Wise. London. Improvements in commutator brushes. (O. Hering, Germany.)

January 24, 1894.

1,532. E. G. Pink. Dublin. An improved system of metering electric currents.

1,542. H. W. C. Cox and R. J. Crowley. Queenstown. Improvements in or relating to *facsimile* telegraphy.

1,582. F. Stone. Derby. Apparatus and process for converting heat into motive power or electricity (or both), and for cooling and refrigerating.

January 25, 1894.

1,657. H. P. Holt. London. A method of and apparatus for communicating electricity to vehicles.

January 26, 1894.

1,686. R. Kennedy. London. Improvements in propelling locomotives by electricity and in apparatus therefor.

1,695. S. D. Williams. Newport, Mon. Improvements in telegraph signal codes and apparatus therefor.

1,698. R. Steenberg. Newcastle-on-Tyne. Improvements in telephone-transmitters.

1,701. C. R. G. Smythe and A. H. Dunnachie. Glasgow. Improvements in and connected with electric conduits.

1,744. W. S. Rawson. London. Improvements in electrodeposition.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d. each.

1892.

18,039. Hargreaves and Bird. Electrolytic cells and diaphragms.

1893.

583. Wright. Electric meters.

982. Brookes (Dibble). Telemeter systems.

983. Brookes (Dibble). Telemeter systems.

1,355. Forbes. Electrothermal plates, tubes, &c.

1,539. Pfluger. Arc lamps.

1,697. Binswanger and Coates. Electric clock.

2,010. Scott. Electricity meters.

2,203. Gwynne. Arc lamps.

4,691. Lithanode and General Electric Co. (Limited) and another. Battery elements.

4,793. Brooke. Electric bells.

5,101. Fletcher. Electrically interlocking signals and points.

5,778. Boult (Kroefler and another). Bleaching solutions by electrolysis.

5,782. Marsh. Telegraph poles.

6,605. Parker. Diaphragms for use in electrolytic processes, &c.

6,723. Snedekor. Electric conductor coverings.

7,703. Johnson (Lattig and another). Electric signalling for railways.

10,623. Murray. Printing telegraphs.

COMPANIES' MEETINGS AND REPORTS.

Telegraph Construction and Maintenance Company (Limited).

The thirtieth ordinary general meeting of the members of the Telegraph Construction and Maintenance Company (Limited) was held at the offices, 38, Old Broad-street, on Tuesday, under the presidency of Admiral Sir George H. Richards, K.C.B., F.R.S.

The MANAGING DIRECTOR (Mr. William Shuter) read the notice calling the meeting and the minutes of the twenty-ninth ordinary general meeting and of the last half-yearly meeting. The minutes having been approved and signed,

The CHAIRMAN said: Gentlemen, before we proceed to the business for which we are met, I should like, with your permission, to offer a few remarks to the meeting. Many things have happened very closely concerning us since we last met, and although these events cannot have had any possible effect on our present position, nor, I trust, are they likely to affect us in the future, and although they are recorded in the report, yet I feel that you would scarcely expect them to be passed over without some remarks from the Chair. The first of these events I have to notice is a melancholy one, the death of our late Chairman. As you all know, Sir George Elliot was one of the first Directors of the Company—in fact, he was one of the proprietors of the business which formed part of our work subsequently, and therefore he always took a deep interest in the affairs of the Company, and he was always keenly alive to its success. I can only say that we regret his loss very much here, and we believe that you will share this regret. At the same time, it must be said that Sir George Elliot died full of years, after a long and useful career. Perhaps this is the time when I ought to say a few words as regards my own position as Sir George Elliot's successor here. They shall be very few, but I should like to give you the reason for it. My colleagues were of opinion that my long connection with the management of the Company probably rendered me one of the most fit persons among us to represent your interests as Chairman, and as this was their unanimous wish, and as I felt also that it was the wish of the chief officers and staff with whom I had been in connection so long, there was only one thing for me to do, which was, to accept the honour they were good enough to offer me, and I can only hope that their expectations will be fulfilled. The third point which I have to mention is also a painful one. I cannot but advert to the death of a very old officer of the Company, who served us faithfully for nearly 30 years—I refer to Captain Halpin. I have no doubt that Captain Halpin was well known to many present. He was the captain of the "Great Eastern" for many years, and of many of our ships, and latterly he was our marine superintendent. Capt. Halpin was, no doubt, one of the pioneers of cable laying, and his great skill as a seaman, and his knowledge of telegraphic engineering, enabled him to do very good service for this Company in its early years. Capt. Halpin may be said to have died in the prime of his life and his usefulness, and we all very much regret his death. Now, I think we may turn to the consideration of the report, and any business that may arise in connection with it. I have no doubt that you have all read the report, and that you will take it as read. You will have seen there that we have done a very fair year's work, both as regards cable manufacturing and laying and as regards our general business in gutta percha at Wharf Road. You will have seen that in various parts of the world we have laid cables covering a distance of nearly 4,000 miles, and we have laid them very successfully; and you also see that we have done a great deal of work in our regular business. This really is the gist of all that I have to tell you. I do not see that I need refer to any of the causes that have produced commercial depression in almost every department, since we have been free from it. I will, therefore, not say anything more at present, but if you desire any further information that I may be able to give you I shall be very happy to do so. I now propose

"*That the report and accounts of the Directors to December 31, 1893, submitted to the meeting be and are hereby received and adopted, and that a dividend of 36s. per share in addition to the 12s. per share, interest or interim dividend paid to June 30, 1893, be paid upon all shares of the Company for the year ended December 31, 1893, and that such dividend be paid free of income-tax.*"

Mr. PHILIP RAWSON: I have much pleasure in seconding the motion.

Mr. CATER inquired what remuneration the Managing Director received, and whether it was an annual sum or was influenced by the work done by the Company, as was the case with the Directors. He saw an item of over £6,000 in the balance-sheet for remuneration to Directors, but as that was exclusive of the Managing Director's remuneration and there was no information in the balance-sheet to tell him what the Managing Director received, he would be glad of the information he had asked for. He also presumed that the £6,000 was divisible among five Directors.

Mr. LITTLE desired to know whether the item of debts owing to the Company, £269,861, was for cables laid last year only, or prior to that.

General TREVOR said that the item of debts owing by the Company and reserves for insurance, debentures, and contingencies, amounted to £564,000. How much of that sum was really a reserve for debentures and contingencies he did not know, nor was this shown in the balance-sheet. Of course, the debenture interest must be paid, and therefore some money must be reserved safely for this purpose. With reference to the reserve for contingencies: "contingencies" was a wide word, and it might include the contingency of a bad year's business, when no profits were made by the Company. He wished to know where this safe reserve was invested, not only to meet debenture interest, but also to meet the shareholders in a year when nothing was earned, and when the shareholders would expect to receive something. The next item in the balance-sheet was called "reserved fund," £50,000, but the shareholders would like to know whether that amount was also safely invested, and whether it was in Consols, in stocks, or in a liquid stock which one could take out directly in the event of a bad year. On the other side of the balance-sheet nearly half a million sterling was taken credit for for value of property, among it being stocks and stores. The auditors' certificate, which he thought was drawn up in a slovenly way, said that they inspected "the inventories of the various stocks on hand of stores, materials, &c." Inspecting an inventory was an ambiguous phrase. The auditors did not state that they were satisfied themselves that the value of the stocks in this inventory was properly calculated or represented a sum of money, which he could not name because it was mixed up in the sum of £475,860. They also said that they had inspected the several securities held by the Company, but they did not say that the £470,520 was really of that value to-day. The questions he desired to ask were, therefore, four. First, where was the reserve for debentures and contingencies invested, and where also was the reserve fund of £50,000 invested; secondly, how did the auditors ascertain the actual value of the stocks on hand and materials, and how did they ascertain that the actual value of the sundry securities was £470,000. Was that Stock Exchange value, or not? The auditors sought re-election. The auditors were always re-elected by the shareholders, and if they were present he would remind them that once they accepted that position they became the servants of the shareholders, and they ought to draw up the accounts in a satisfactory way, and not lump up items in a manner which might be—he did not say it was so in this case—satisfactory to the Directors only. It would depend on the answer he received to his questions whether he moved a resolution.

The CHAIRMAN: In reply to Mr. Cater's question, I have to say that the Managing Director is paid an annual salary, and not on any amount of profit that may be made. Formerly there were two Managing Directors, but there is now only one. The Managing Director's duties are very onerous indeed, and his salary is in accordance with that state of things. It is not necessary to show it. I ask whether any gentleman here, if he held this business as a firm, would like these particulars handed to the public. You are surrounded by safeguards. You have a most eminent firm of accountants and your own auditors, and I say that you cannot be more secure than you are. It is a very difficult thing to ask me to go into details of accounts which ought not to be submitted to the public. The Directors' remuneration is settled by the Articles of Association of the Company. The Directors are empowered to pay the servants of the Company what salary they think fit. You may ask us the salary of every member of the staff, but it would not be a proper thing to state.

A SHAREHOLDER said he thought there could be no reason for withholding from them the Managing Director's salary.

The CHAIRMAN: I do not think it is in accordance with custom. There is no objection to it, but I do not think it is a matter that should be made public. You have economised your Managing Director's salary by one man doing the work of two. Mr. Cater asked among whom the Directors' fees were divided. They are divided among seven Directors. With reference to the question about the reserves. the ordinary reserve of the Company is £50,000, which is invested in Consols, and is available whenever it is wanted. We are authorised by our Articles of Association to make reserves for anything we deem fit. In a Company like this you are obliged to make reserves. You are working, not like a railway, above ground, but under the water, and are liable to all sorts of accidents. You therefore have a reserve for insurance, for the refitment of your ships, and for a variety of things, but I think it would be very wrong to make all these particulars known to the public. The shareholders get their dividend. If we paid you no dividend, and made a large reserve, these questions might be asked.

General TREVOR observed that his question was what would the Directors do in a year when the Company earned nothing.

The CHAIRMAN: That question has never arisen. We have always paid good dividends, and probably because we make these reserves. If we earned a large sum and paid you nothing you might ask such a question, but such a thing has never happened. I should have thought the meeting would have been satisfied with a good dividend, and have allowed the Directors to make such arrangements in the future as would ensure their receiving a good dividend. That has been the arrangement of the Directors for years, and I think that until last year you had the same dividend as we propose to pay you now. You must not, however, regard this Company as if it were a railway company or a company whose results are more or less certain every year. This Company is uncertain in every way, and it is only by great caution that the Directors have been able to do as well as they have done and to make no mistakes, and to make sure of paying a dividend. This is what we have always done so far. I am sorry that any one should ask questions which cannot be for the benefit of the Company, and which may be very much to its disadvantage.

A SHAREHOLDER: I regard it as a covert censure on the Directors to put such questions.

General TREVOR said that he had put four questions, one of which the Chairman had replied to, and he desired answers to the other three questions before any other shareholder addressed the meeting. At the request of the Chairman he repeated his other three questions.

The CHAIRMAN: Perhaps I had better ask our accountant to reply to them.

Mr. SHUTER, in answer to Mr. LITTLE, said that the £270,000 owing to the Company represented trade debts, and they were all perfectly good. The greater part of them were incurred last year.

Mr. DEVER said he had been asked to explain how the auditors satisfied themselves as to the value of the stocks on hand. The auditors were not present, but on that occasion he would reply to the question, as being the head of the clerical staff of the Company. His firm acted as accountants to the Company, but not as auditors, but he was able to tell

Digitized by Google

the meeting how the auditors satisfied themselves that the figures were accurate. The stocks were taken—and he was sure every man of business will admit that this was the only correct and possible way to take them—by the staff of the Company, and the head of each department weighed, measured or counted the quantity of stuff he had on hand. These calculations were afterwards put into the form of an inventory. It was not the duty of auditors—and he thought it was hardly a duty that any body of shareholders would try and cast upon professional auditors—to check the stocks of a manufacturing concern like theirs. The auditors had no practical knowledge of the items; they would hardly know their names and scarcely recognise their existence if they saw them, and they would utterly fail in putting any value upon them. The shareholders might depend upon it that the best way of checking them was to have the items dealt with in the manner he had stated by those who understood them. His firm used these inventories after submitting them to such checks as they could before the auditors saw them. That check went to a sort of examination of the prices attached to the items where the knowledge of the head office might be brought to bear, and went to the clerical accuracy or otherwise of this very large and complicated stock sheet. The accountants gave to them as much check as they felt could be given to them in estimating their value. The second question was how did the auditors satisfy themselves—or did they satisfy themselves at all—as to the value of the securities held by the Company. They did so, and the accountants did so before the statement came to the auditors. The accountants prepared a most elaborate schedule of the investments of the Company, and they submitted that to the auditors priced out in two different ways. There were two classes of securities held by the Company. One was solid investments of the Company's funds. These were held up at cost, and it might be interesting to the meeting to know that the value at that moment of the securities held up at cost was very largely in excess of the figure at which they appeared in the accounts. The other section of the securities was made up of shares, bonds, stocks and other securities coming into the hands of the Company by way of payment for work done. These were held up at market prices and could be realised very quickly. He assured them that there was no fear that the investments of the Company were not both very good and very liquid, and were held up at fair and realisable figures. Speaking for the moment for the auditors, he should say that the form in which the accounts were presented to the shareholders was not the affair of the auditors at all. An honourable proprietor had, he thought, passed a slight degree of blame on the auditors for submitting the accounts in their present form, but he repeated that that was not the auditors' business. The accounts were rendered to the Directors in the form in which they had been accepted and agreed to by the shareholders themselves. Year after year the accounts had been presented in their present form. It had been considered by the Directors, without doubt, that this was the best form, but it had always satisfied the shareholders. It was not for him to say one word in favour of giving either more or less information, but the Board and the shareholders had to settle this matter between themselves The shareholders had—he thought wisely—determined that this form was most complete and fair, and studied the real interests of the Company itself. If the shareholders desired something else he thought it would rather tend to display a want of confidence in those who were managing the Company's affairs. Much was kept back from the accounts, and he thought wisely kept back. The shareholders had never pressed for it, and he thought they had acted wisely in this, and he would advise them not to do so, because it would not be for the general interests of the Company.

General TREVOR thought that as they had been told that the reserved fund of £50,000 was in Consols it might be stated so in the balance sheet in future. It would save questions from being put.

The CHAIRMAN: It would be very easy to answer such a question by stating that the reserved fund was in Consols.

Mr. GEORGE W. CAMPBELL said that it had been invested in Consols for the last 25 years.

Gen. TREVOR said that nothing could be more satisfactory than this statement.

Mr. CAMPBELL, continuing, said that if it was stated that the reserve fund was in Consols they would only be asked what the other investments were in, and they could not mention all their investments.

Mr. RAWSON remarked that it had not been the policy of the Company to enter into details because it had been thought that it would be inadvisable to do so. Hitherto the shareholders had had confidence in the Directors, and he thought wisely. All their reserves were in the best conceivable securities, they were all liquid, and were not mixed up in the general business of the Company at all.

Mr. WHISH said it was very strange to him that such a severe inquiry should have taken place that day, in view of the fact that from year to year the shareholders had accepted without a single murmur the statement of Sir George Elliot that it was advisable, in the interests of the Company, to keep certain things in the background.

The CHAIRMAN then put the resolution, and it was carried unanimously.

Mr. CAMPBELL afterwards proposed the re-election of the retiring Directors, Admiral Sir George H. Richards and Mr. Philip Rawson. The Directors, who had had the opportunity of knowing Sir George Richards and seeing him at work for the last twenty years, considered it a great advantage to have that gentleman not only as a Director but as their Chairman.

Mr JAMES PENDER, J.P., seconded the motion, which was carried unanimously.

Mr. BLANFORD then proposed the re-election of the auditors, Mr. John Gane and Mr. Patrick A. Glegg. He thought they might congratulate themselves on the exceedingly interesting statement they had had regarding the auditors' work.

Mr. HEWAT seconded the motion, which was adopted.

Mr. RAWSON said he desired to thank the shareholders for their renewed confidence in re-electing him. It would be impossible, he added, to find any Company in London that was sounder than theirs in every way. Nothing could exceed the care which was taken on every point, and the shareholders might leave the meeting perfectly satisfied that every item in the report was perfectly honest and safe.

Mr. BLANFORD then proposed a vote of thanks to the Chairman and Directors, which was seconded by General TREVOR.

Mr. WHISH said he thought that some expression should come from the shareholders' side of the table regarding the loss which had been sustained by the Company in the death of their late Chairman, Sir George Elliot, who was a most gifted man. He also thought that the shareholders should accord a hearty welcome to Sir George Richards in the position which was now filled by that gentleman.

The resolution was carried by acclamation.

The CHAIRMAN: On behalf of my colleagues and myself I return you our best thanks for your kind vote. Our great object is to have your confidence, and without that I do not know that we should care particularly to fill the position we do.

The proceedings then terminated.

Notting Hill Electric Lighting Company (Limited).

The seventh ordinary general meeting of the Notting Hill Electric Lighting Company (Limited) was held at the Company's Registered Office, Bulmer-place, High-street, Notting Hill, on Tuesday last, Prof. Wm. Crookes, F.R.S., presiding.

The SECRETARY (Mr. R. G. Rawkins) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said:—Gentlemen, before I refer to other matters let me take the earliest opportunity of congratulating you on the success of the Company's working during the past year. The result achieved has quite come up to our expectations, and I hope this will also be the opinion of the shareholders. I will briefly go over the accounts as they are before you. They are published in such detail that little explanation is needed, but there are one or two items about which a few words of explanation and comment may not be unnecessary.

Share Capital.—Little need be said on this account. As a certain portion of the capital expended by way of preliminary expenses, &c., was unremunerative and not balanced by any visible asset, this portion is represented by the £5,500 Founders' shares, leaving the rest of the capital practically all represented by the visible assets of the Company. The Directors consider this to be a proper and business-like way of arranging the capital account. As to the Loan Capital Account would draw attention to the fact that according to this statement the Company is free from any mortgage or debenture debt, and the whole of its freehold and other properties are uncharged. In fact, our only debts amount to £926. 19s. 3d., and consist of certain monies advanced by consumers to pay for small extensions of mains which the Company has agreed to allow to be taken out in current, thus preventing any risk being incurred by the Company undertaking speculative extensions. It has been the object of the Company to make the subscribed capital represent the actual amount of capital expended. It will be seen from this account that this has practically been done. The item of £744. 10s. appearing against mains in this account has been spent during the year in making small extensions to connect up houses requiring the light, and in most cases a satisfactory return on the capital outlay has been guaranteed. Another item of £522. 11s. 11d. for patents has been explained fully in the report. The expenses incurred by the losing side for costs and licence were necessarily heavy, and were agreed to be divided rateably between the defending companies. The £522. 11s. 11d. represent the proportion which we had to pay. For this we have a licence to use the three-wire system through the whole of our area. It is estimated that the extra cost of construction, had this system not been adopted, would have amounted to between £5,000 and £6,000.

As to Revenue Account the figures for the year 1892 have been printed in the margin of this account, to enable shareholders to compare the amounts of receipts and expenditure for the two years. The cost of coal during the past year is seen to be identical with that of the previous year. The amount burnt, however, has been larger and the revenue from the sale of current is about £1,000 more than before. This is due to various causes. Notwithstanding the protracted coal strike the price paid was some 3s. per ton less than that paid in 1892. On the first rumours of a strike, in consequence of the energy and foresight of our manager (Mr. Schultz), sufficient stock was laid in to carry us over any time of anxiety. Had this not been done the Company might have been seriously affected, as at one time coal was not at all obtainable. Consumption of coal has also been saved by various alterations in machinery. The engines were not worked up to their full power in 1892; indeed, we have not yet got them working to their full load, and it may, therefore, be estimated that next year the increase of revenue from current will be still larger in proportion than the expenditure for coal. The Directors have decided, in order to keep the fixed charges on as low a basis as possible, not to increase the engineer's salary, which is only £250 per annum, but, in order to remunerate him more in accordance with the market value of his services, have decided to pay him every year 5 per cent. on the amount of money distributed in dividend. I need hardly say that this will give Mr. Schultz an interest in the success of our undertaking (although, as he has proved by his services, it was not required), and at the same time will help to reduce the dead weight of fixed charges. The Directors would call attention to the enormous amount of rates and taxes, which come to £225. 15s. 11d., mainly caused by the very high valuations put upon the Company's works and mains. The Directors consider that the valua-

Digitized by Google

tion for machinery used in the earning business should be fixed at a reasonable rate, and not at such an amount as would bring the rates and taxes up to 3s. in the £ on the net revenue of the Company. Householders live in houses of which the rent is one-tenth of their income, and on the same basis the total rateable value of the buildings and machinery, &c., of the Company should not be fixed at more than one-tenth of its gross income.

Rents payable.—This item will drop out in future accounts.

Directors' remuneration.—The Directors, who have already on former occasions proved their willingness to help the Company by concessions in respect to their fees, again do not propose to draw the full amount they are entitled to, viz., £1,000 per annum, until the Company can properly bear it, but in order to enable the Company to start the new year free from all liability, they have agreed to take £440 in full discharge of fees due to them, amounting altogether to £2,125.

Auditors.—During the past half-year the Directors have had the accounts submitted to a running audit by Messrs. Fox, Sissons and Co. In addition to this there has been the annual audit by Messrs. Deloitte, Dever and Co., as well as another annual audit by the auditors appointed by the Board of Trade, for which last item there is a charge of £24. 18s. 0d. Messrs. Deloitte, Dever and Co., recognising the fact that this triple audit was unnecessary, have voluntarily suggested that they should not again present themselves for re-election, and recommend that Messrs. Fox, Sissons and Co., who have a very intimate knowledge of the Company's accounts, should continue the system of running audit on behalf of the shareholders if the shareholders decide to elect them, leaving the annual audit to the officials of the Board of Trade. This would relieve the Company of considerable extra expense, and at the same time will provide for the shareholders the additional security of a running (*i.e.*, a continuous) instead of merely an annual audit.

Law Expenses.—The Directors call attention to the fact that the law expenses last year were only £13. 13s. As all questions of forms, agreements, and technical matters had been settled during the first two years of the Company's formation it was possible to make great economies on this item.

You will see that the profit on the year's working amounts to £1,481. 7s. 1d., a sum which compares most favourably with that of the previous year, when a loss of £137 would have resulted but for a fee of £250 from the New Telephone Company. The year before the actual loss was £554. 18s. 6d.

Net revenue account. — As you will see, the balance of profit appearing in the net revenue account, after writing off the loss of £347. 16s. 4d. brought forward from the last account, and allowing for a small amount of interest, amounts to £1,081. 16s. 1d. Out of this balance the Directors recommend the payment of a full dividend on the Preference shares to December 31st last. I must say I am extremely pleased to have the opportunity of proposing the payment of the Company's first dividend. The proportion of increase of revenue is about 10 per cent. less than the increase in the number of lights. Basing an estimate on the exact number of lamps on our mains on December 31, 1893, and without allowing for any increase whatever during the whole of 1894, a careful estimate shows a net revenue of £2,500, a sum which will enable about 2½ per cent. to be paid on our Ordinary shares at our next annual meeting. Any increase in the number of lamps or in their productiveness (and it is hardly necessary to mention that further applications have been received since the turn of the year) would be an addition to this revenue.

In regard to depreciation fund, the Directors have not passed any money to this account, but they have expended out of revenue and charged against the year's expenses sums amounting to £617. 5s. 6d., equal to about 1 per cent. dividend on the Ordinary shares, in the way of renewals and reconstruction. The Directors did not consider that it was a proper thing to put this amount to capital expenditure and then to write off, say, 1 per cent. on the capital for depreciation fund account; it would have had the same effect, but would have unduly augmented the capital account. The whole of this work has been carried out by our own efficient staff under the engineer's supervision, and the cost has been considerably less than would have been paid had others been called in to do the work. All our work is now concentrated under one roof, and the expenses all round have been reduced to the lowest point consistent with thorough efficiency. The saving will be more apparent during the current year. The mains and machinery have done their work well during 1893, no accident of any kind having occurred except the flooding of a small part of the culverts with water on two occasions in January, owing to a fire plug being blown out, causing a loss of about 250 units. It is gratifying to note that the London County Council, probably in consequence of the representations made to them by this Company, have replaced the whole of the old-fashioned plugs at a considerable expense, and up to the present with very satisfactory results, as no case of the kind has occurred so far during the present winter. The lamp patent expired in November last, and very good lamps can now be bought at 1s. to 1s. 6d. each. This will materially reduce the cost of installations, and should be some inducement to householders not at present using the electric light to take it. As you see by the Report the mains at the present time run past or opposite to 980 houses which are not yet taking a supply of current.

The number of lamps on our mains have increased by 2,715 during the year. This must be considered satisfactory, although the previous year's increase was 3,382. A large number of these were from the Phillimore extension. The average lamp earnings for the year still shows a tendency to sink, being only about 6s. 6d. per lamp. This can be partly accounted for by the exceptionally bright weather during the last quarter of the year, and the almost total absence of fog, the majority of our customers having consumed less than for the corresponding period of the previous year. Another fact showing that the bright weather was responsible for the reduced consumption is that although the number of lamps during the last quarter was about 25 per cent. more than the previous year, the corresponding increase in current consumed was only about 15 per cent.

The Company's sheer cost per unit is lower than that shown in accounts published in 1893 of any other London company. This is all the more remarkable inasmuch as our output is the smallest. At very little additional cost we could supply considerably more current, thus still more reducing the cost per unit. In conclusion I can assure you that the Directors will continue to do the best in the interests of the shareholders. But the fact that we hold over £16,500 of the capital in our own names is I think a sufficient guarantee of this, and now we have turned, and more than turned the corner, you will agree with me that the future success of our Company is assured. I now beg formally to propose:—

"*That the report of the Directors and the accounts to the 31st of December, 1893, submitted to this meeting be, and at the same time are, hereby approved and adopted, and that a full dividend to the 31st December, 1893, on the Preference shares be and is hereby declared, payable forthwith.*"

Mr. ALEXANDER HOWDEN seconded the motion.

Mr. J. S. BEALE, in supporting the resolution, paid a tribute to the Chairman and Directors for the very satisfactory manner in which the business of the Company had been carried on since it was started. He thought that the future of the Company was assured, and that the increase of revenue in time to come would be in a far greater ratio than the expenditure. He suggested that it might be advisable to convert the Founders' into Ordinary shares, so as to obviate a divided interest between the two classes.

The CHAIRMAN, while thanking Mr. Beale for his compliment to the Board, said that the suggestion of converting the Founders' shares was somewhat complicated, but it would be borne in mind and dealt with as opportunity offered.

The resolution was carried.

Mr. REEVES proposed, and Mr. MATTERSON seconded, the re-election of Mr. A. Howden and Mr. J. T. Jervis to their seats at the Board, which was agreed to unanimously.

On the motion of Mr. BRADFORD, seconded by Mr. DUTTON, Messrs. Fox, Sissons and Co., were appointed auditors for the current year at a remuneration of thirty guineas.

Mr. DUTTON proposed a vote of thanks to the Chairman, Directors and staff, and suggested that the Directors might increase the business of the Company by endeavouring to get more street lighting to supply, which he thought would be a very good advertisement for the Company amongst private consumers.

The CHAIRMAN, in expressing his acknowledgment, said that the idea of being advertised in the manner referred to by Mr. Dutton was one which they all liked, but it would not do for the Company to lose money by it. They had asked the Vestry to allow them to light the streets at cost price, but that body could not see its way to fall in with the proposal.

The proceedings then terminated.

Liverpool Electric Supply Company (Limited).

The ordinary general meeting of this Company was held last Friday in the Saleroom, Exchange Station-buildings, Mr. A. H. Holmes presiding. In their eleventh annual report the Directors were again able to announce a satisfactory increase in the number of lamps supplied from the Company's mains, the total number connected on December 31st last being equivalent to 25,784 16-c.p. lamps, as against 20,254 on December 31, 1892. The balance to the credit of the profit and loss account, including £4,851. 19s. 1d., paid for interim dividend in September last, was £12,710. 16s. 6d. This sum included the balance brought forward from 1892, and the sum of £297. 8s. 7d. received for premiums and interest on share account. The Directors recommended the payment of a dividend for the half-year at the rate of 5 per cent. per annum, absorbing £5,308, adding £1,000 to reserve fund and carrying forward the balance of £1,550 to next year's account.

The CHAIRMAN, in moving the adoption of the report and accounts, said they proposed to pay what he hoped they would think was a good dividend. They had had a very calm and usual year. He had nothing sensational to report. There had been the coal strike, which he thought had affected every industry in the country. It had affected not only private companies but public industries, and it certainly had affected their own Company by slightly reducing the balance due to them. The exceptionally fine weather in the autumn prevented as much light being used as had been used in previous years. Another unusual thing had been the extension of the city boundaries contemplated by the Corporation. This, he supposed, they might now consider to be almost an accomplished fact. They had made satisfactory arrangements with the Corporation, but he need not enter into them, as the change in the boundaries, although decided upon, would not come into existence until, at the very earliest, the end of this year. The Company had maintained their contract with the public, and had given them good and efficient light. They had had fewer complaints than they had ever had before, and he thought they might now say that the electric light throughout the city was certainly as much to be relied upon as the gas was. Such complaints as they had had were mostly owing to causes entirely beyond the control of the Company. There was still the question of cost. They had been accused of charging exorbitant prices for their light. He thought that a glance at their balance-sheet would show that the dividend they paid was not an exorbitant one, but was one they were entitled to expect. As a matter of fact they had considerably reduced the price to their customers. If they had charged the same price in 1893 as they did in 1891, it would have given them £27,000, as against £25,000. Therefore, taking the two years they had given to their customers the sum of £2,365.

Digitized by Google

There had also been a considerable saving in the lamps. In November the Edison and Swan patent came to an end, and the lamps which they used to supply to their customers at 3s. 6d. they were now supplying at much lower prices. They had a new lamp which he was sorry to say was a foreign lamp, and made in Holland. They gave a good lamp for 1s., and the light from it was much superior to that of the old lamp. They had thus saved to their customers an amount of something like £1,500. At present they could not do anything towards further reducing the cost to consumers. They anticipated a large increase in the number of lights, and with that increase they would be able to charge a lower price. The increase in the number of lights had been a very satisfactory one during the past year, being over 26 per cent. There was no doubt they would have a great many more lights in future, and it would be absolutely necessary to extend their premises, and provide new boilers at two of their stations. Many of their most fashionable shops in Lord-street and Church-street were now lighted by electricity, and he thought the time was coming when most of the shops in the principal streets would be similarly lighted. The rulers of the city did not seem to see their way to use the light for public purposes. He regretted that their streets and all the public buildings belonging to the Corporation were not lighted by electricity ; still he hoped that this would come in time. The expenditure on capital account during the year, including a proportionate charge for general expenses, had been £53,777. They now proposed to spend something like £29,000, and in order to do that they had issued a circular calling up the remaining 10s. per share. They continued to write off a considerable amount for depreciation, and they had put £2,000 to the renewal fund, and they had also increased the reserve fund from £2,500 to £3,500. The total depreciation they had written off since the Company commenced amounted to £26,000, which was neither too little nor too much.

In reply to Mr. James Lister, the CHAIRMAN said originally the time fixed for the acquirement of the property by the Corporation was 1900, but a new arrangement had been made in connection with the city boundaries extension scheme, which would give the Company an additional 42 years.

The report was duly seconded and adopted.

Messrs. Samuel H. Holme and J. C. Vaudrey were re-elected Directors.

Mr. JAMES LISTER proposed that 750 guineas, free of income tax, be placed at the disposal of the Board of Directors as remuneration for their services during the past year. They owed to the Directors and shareholders a debt of gratitude for having introduced this system of lighting into a great city like Liverpool.

Mr. J. GIVEN seconded the motion, which was agreed to.

Mr. W. L. JACKSON was re-appointed auditor.

A vote of thanks to the Board of Directors and to the officials of the Company concluded the proceedings.

Cambridge Electric Supply Company (Limited).

The following is the report of the Directors to be submitted to the second annual general meeting, to be held at the offices, 2, Sydney-street, Cambridge, on Tuesday next, the 6th inst., at 12 o'clock :—

Your Directors have pleasure in reporting that the prospects of the Company are satisfactory. During the last twelve months, lamps equivalent to about 6,000 lamps of 10 c.p. have been connected to the Company's mains, making a total at the present time equal to 8.000 lamps of 10 c.p., and there is every prospect that the number will be largely increased during the present year. The plant, during the last three months, has been fairly loaded, and has worked to the satisfaction of the Directors, but owing to the coal strike in the autumn, a considerably increased price had to be paid for fuel.

It seemed to your Directors that it would be inexpedient to commence a profit and loss account, in respect of supply of energy, with only a small portion of the machinery at work, and they have therefore deemed it advisable to carry all receipts and expenditure under this head up to June 30th last to capital account. The Company has made a profit of £268 to December 31st last, and it is anticipated that with the additional lamps lately connected, and those which will shortly be connected, your Directors will be able, at the next annual meeting, to advise the payment of a substantial dividend for the current year.

Your Directors have thought it necessary to apply to the Local Authority for their sanction to the temporary suspension of the supply of current, between the hours of 2 a.m. and 5 p.m. in summer, and 2 a.m. and 6 a.m. in winter. A supply during these hours would involve the shareholders in heavy additional expenditure at the present early stage of the Company's operations, without any corresponding benefit to the general public. Your Directors, however, hope that the applications for current will shortly be sufficient to justify them in making the supply continuous, and it will be their endeavour to effect this at the earliest opportunity.

The Rev. G. B. Finch and Mr. J. B. Simpson retire by rotation ; the latter is eligible and offers himself for re-election. The Directors also recommend the election of Dr. P. W. Latham and Mr. W. C. Hall.

Birmingham Electric Supply Company (Limited).

The report of the Directors, to be submitted at the ordinary general meeting of the Company, at the offices of the Company, 14, Dale-end, Birmingham, on the 8th inst., at 12 o'clock, is as follows :—

The amount of net profit, including the balance of £264. 1s. 8d. carried forward last year, is £5,247. 16s. 8d. ; out of this the Directors recommend the payment of a dividend of 4 per cent., absorbing £2,715. 6s. 7d., placing £1,872. 18s. 1d. to the credit of the depreciation reserve fund, and a further sum of £250 towards the general reserve fund, and carrying forward the balance, £409. 12s., to next year's account. The capital expenditure during the year amounts to £5,356. 10s. 9d., and includes the addition of one new steam engine and dynamo machine, and further extension of the Company's mains and services. The total number of 16-c.p. lamps or their equivalent on order on December 31, 1892, was 8,329, and on the same date in 1893 the number was 10,223. The demand for the light still continues to increase, and the additions since the close of the financial year bring the total up to 11,034. The Directors venture to think that the progress made during the year that has passed will not be considered unsatisfactory, taking into consideration the depressed condition of trade, the prolonged coal strike, and the phenomenally clear days throughout the winter months.

At the last annual meeting your Directors reported that they considered, owing to the demand for the light in some of the outlying districts, that it would be an advantage to the Company to extend its operations to Edgbaston and the jewellers' quarters. The necessary statutory notices have been given, and a draft of the new Provisional Order for the additional areas is now under discussion with the Corporation.

Two Directors, Mr. Henry Buckley and Mr. J. F. Albright, retire by rotation, and, being eligible, offer themselves for re-election ; as do the auditors, Messrs. Sharp, Parsons and Co.

City of Bath Electric Lighting and Engineering Company (Limited).

The following is the report of the Directors of this Company to be presented at the third annual general meeting to be held at the works, Dorchester-street, Bath, on Wednesday next, the 7th inst., at 2.30 p.m. :—

In submitting the balance-sheet and profit and loss account for the year ending December 31, 1893, the Directors are pleased to be able to state that the year's working shows a substantial improvement over 1892. The receipts for the current sold are increasing satisfactorily, the total income from this source being £4,621, as compared with £4,301 for 1892. The number of lamps installed has risen from 6,420 to 7,070, and the Directors anticipate considerable additions during 1894. The policy of charging by meter only has been steadily pursued, a plan alike fair to the consumer and the Company.

The Directors have appointed Mr. G F. Metzger as engineer and manager, and he commenced his duties in May. With his help considerable economies and improvements have been effected, whilst the efficiency of the station and the plant has been fully maintained.

These economies have resulted in a profit for the past six months of £464, notwithstanding the additional expenditure involved by the coal strike. Had it not been for a loss on the first six months of £276, and the loss of £277 brought forward from last year, the profit for the year would have been very satisfactory. As it is not anticipated that similar losses will again occur, the Directors look forward with every confidence to 1894.

It may be satisfactory to the shareholders to be informed that the existing machinery and plant are capable of a largely increased output of current without materially increasing the running expenses.

The financial position of the Company has also been considerably improved since the last report, and since the closing of the year's accounts the unpaid balance of purchase-money, amounting to £1,242, has been paid.

Since the last meeting Mr. E. Garcke, Major-General J. G. Jervois, Mr. H. N. Garrett, and Mr. H. G. Massingham have retired, and the Directors have elected Mr. B. H. Van Tromp and Mr. J. B. Wood to the Board. The following Directors retire, and offer themselves for re-election :—Mr. Alfred Pitman, Mr. Ernest Pitman, and Mr. J. B. Wood. The Directors waive their fees for the past year.

NEW COMPANIES, STATUTORY RETURNS, &c.

In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.*]

ALDERSON'S PATENT DAY AND NIGHT CLOCK COMPANY (LIMITED).—This Company was registered on February 21st, with a capital of £5,000, in £1 shares, to carry on the business of manufacturers of, and dealers in, timepieces of every description, and of lamps of all kinds, and also of apparatus connected with the manufacture, consumption, supply, and distribution of electricity, whether for illuminating clocks, or for light, heat, or motive power.

J. HOPKINSON AND CO. (LIMITED).—This Company was registered on February 24th, with a capital of £40,000, in £10 shares, to acquire the business of mechanical engineers and boiler makers carried on at Huddersfield by J. Hopkinson and Co., and to carry on the business of mechanical and electrical engineers, machine and engineering tool makers, boiler and boiler mountings makers, electrical, hydraulic, and pneumatic apparatus manufacturers, &c. The first Directors are :—John A. Hopkinson, Joseph Hopkinson (life Directors), Frank A. Hopkinson, and Robert A. Hopkinson.

M'DOWALL, STEVEN AND CO. (LIMITED).—This Company has been registered in Edinburgh to take over the business of M'Dowall, Steven and Co., ironfounders, in Glasgow. The capital is £200,000, in 4,000 Preference and 16,000 Ordinary shares of £10 each.

Digitized by Google

AKESTER ELECTRIC SYNDICATE (LIMITED).—The annual return of this Company, made up to January 12th, has been filed. The nominal capital is £15,000, in 300 shares, of £50 each: 177 of these have been taken up, and 100 have been issued as fully paid. Upon the remaining 77 a call of £37. 10s. per share has been made, resulting in the payment of £2,837. 10s., and leaving £50 in arrears. Nine shares have been cancelled since last return.

CHAGFORD AND DEVON ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to January 11th, has been filed. Out of a nominal capital of £2,000, in shares of £1 each, 1,074 have been taken up, and 750 issued as fully paid. The full amount has been called and paid on the remaining 324 shares.

CHELMSFORD ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company, made up to January 3rd, has been filed. The nominal capital is £10,000, divided into 7,500 Preference and 2,500 Ordinary shares of £1 each, 5,507 Preference and 2,378 Ordinary shares have been taken up, and the full amount called on each, resulting in the payment of £7,878, and leaving £7 in arrears.

CONSOLIDATED TELEPHONE CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—The annual return of this Company, made up to June 26, 1893, was recently filed. The nominal capital was then (since reduced) £307,545, divided into 75,000 £6 per Cent. Preference shares of £1 each, 224,850 Ordinary shares of 14s. each, and 75,150 Ordinary shares of £1 each. 27,637 Preference and 224,850 14s. Ordinary shares have been taken up, the full amount called, and £185,032 paid.

CROMPTON ELECTRIC SUPPLY COMPANY OF AUSTRALIA (LIMITED). The annual return of this Company, made up to January 3rd, has been filed. The nominal capital is £50,000, divided into 9,500 "A" and 500 "B" shares, of £5 each. 3,115 "A" and 500 "B" shares have been taken up, and the whole of the latter issued as fully paid. Upon the "A" shares the full amount has been called, resulting in the payment of £15,275, and leaving £300 in arrears.

WOODFIELD SYNDICATE (LIMITED).—The annual return of this Company, made up to November 7, 1893, was recently filed, when the whole nominal capital of £12,000, in Ordinary shares of £1 each, was taken up and fully paid. A return for 1894, made up to February 13th, and filed with the foregoing, exhibits no change.

CITY NOTES, &c.

BELL'S ASBESTOS COMPANY (LIMITED).—A dividend at the rate of 5 per cent. per annum, free of income-tax, has been declared by the Directors of this Company. The amount carried forward is £1,781.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended February 25th were £945, as against £943 in the corresponding period of last year, being an increase of £2. The total receipts for the half-year amount to £7,610, as against £7,743 for the corresponding period of last year, a decrease of £133.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The prospectus is issued, and will be found in our advertisement columns, of an application for subscriptions for £100,000 Five per Cent. Debenture stock (forming part of a total issue of £400,000) of the City of London Electric Lighting Company (Limited), the price of issue being £115 per cent., redeemable by the Company at £125 per cent., by six months' notice after December 31, 1910. Subscriptions for this issue will open to-day, at 10 a.m., and will close for both town and country at 4 p.m. on the same day. Instalments are payable: £10 on application, £25 (including the premium of 15 per cent.) on allotment, £40 on April 30th next, and £40 on June 30th next. Interest for the period ending June 30th will be calculated from the dates of the respective instalments (exclusive of premium), and will subsequently be payable half-yearly on Jan. 1st and July 1st in each year. The whole of the 40,000 Ordinary and 40,000 Preference shares of £10 each in the Company have (the prospectus states) been issued, and are fully paid. The Debenture stock is constituted by a trust deed made between the City of London Company and the Electric and General Investment Company (Limited), as trustees for the debenture holders, and will operate as a first charge, by way of floating security, upon the whole undertaking and property of the Company, subject to the conditions set out in the prospectus, but cannot be redeemed, except at £125 per cent. Gross revenue, at the estimated rate of £64,000, is now being earned by the Company, of which £13,000 is derived from public lighting and £51,000 from private lighting, and it is anticipated that the fourth section of the main buildings of the Company's generating station, at Bankside, will be completed in March current, offering accommodation for plant sufficient for nearly 300,000 8-c.p. lamps. Application must be made on the forms accompanying the prospectus, which must be forwarded to the bankers, the London and Westminster Bank (Limited), Lothbury, London, E.C., from whom application forms can be obtained, as well as from the brokers, Messrs. Foster and Braithwaite, 27, Austin Friars, E.C., or from the Offices of the Company, 1 and 2, Great Winchester-street, E.C.——Dividend warrants on all the Preference shares of this Company have been posted to shareholders.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have decided, subject to audit, to recommend the payment of the dividend at the rate of 10 per cent. per annum on the Preference shares, and a dividend at the rate of 4 per cent. per annum, free of income tax, on the Ordinary shares, both for the half-year ended December 31st last.

ELECTRO-CHEMICAL COMPANY (LIMITED).—We are informed that letters of allotment for this Company's application for capital were posted on Tuesday last. We are asked by Messrs. A. Norman Tate and Co., of Liverpool, to state that the Mr. Walter Tate referred to in our note last week, as "of Messrs. A. Norman Tate and Co.", is not connected with that firm.

GENERAL HYDRAULIC POWER COMPANY (LIMITED).—The annual meeting of this Company was held on Wednesday last. In moving the adoption of the report, the Chairman stated that the number of the Company's machines contracted for to December 31st last showed an increase of 177 over the previous year. At Liverpool they were making satisfactory progress. They had incurred a large expenditure on capital account in connection with the City-road, London, pumping station and the new mains connecting it with the general system. When this was completed they would have an additional capacity of 40 per cent. With regard to the electric light, they had decided in the first place to light up their London pumping station, and he believed they would be able to supply the light with advantage to the consumer.

GREAT NORTHERN TELEGRAPH COMPANY.—The list is issued of 100 debentures of £100 each, series "B," 1883, which have been drawn for payment on March 1st by Messrs. C. J. Hambro and Son, 70, Old Broad-street, London, E.C.

KESWICK ELECTRIC LIGHT COMPANY (LIMITED). — The annual report of this Company has just been issued. The Directors state their inability to recommend a dividend, being obliged to declare a loss on the past year's working of £69. 5s. 7d. The use of steam instead of water (which the Directors have been unable to avoid) is of itself sufficient to account for loss of profit, but the Directors have confident expectations of being able very soon to use the whole water power of the river, without which success is impossible. The trade of the past year shows an increase of 51 lamps, representing £66. 9s. 3d. in receipts. There appears to be a decided disposition in the neighbourhood for people to avail themselves of the light, but as the output is restricted the Directors cannot push business as they would like to do. Were ample machinery supplied for procuring the current they feel confident of a fairly satisfactory result; but to obtain this result it will be necessary to procure more capital. Considerable additions to and alterations in plant, wiring, &c., will be necessary to work an increased and remunerative trade, which cannot be expected from the present small station.

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The half-yearly coupons, falling due on March 1st, of the £100,000 Six per Cent. Debentures of this Company will be paid by Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, London, E.C., on and after that date.

MAXIM-NORDENFELDT GUNS AND AMMUNITION COMPANY (LIMITED). A meeting of this Company was held last week, at which Admiral Sir Edmund Commerell, V.C., G.C.B., presided, and in dealing with the prospectus of the Company he stated that sometimes they were very busy in their regular business of gun-making, but at others they found it difficult to find employment for their numerous staff. They had therefore decided to take up outside work. They had already taken up the subject of electricity, and found that their workmen could turn out electrical plant of as good quality and workmanship as the Maxim guns. The Directors, therefore, considered that electricity offered them an excellent field for employment in the future, and they were determined to take up anything that presented itself in this branch of industry.

MERSEY RAILWAY COMPANY.—At the meeting of shareholders, held last week, a question was put to the Chairman as to whether the Company would not benefit considerably if electricity were used as the motive power on the line. The Chairman, in reply, said that he, personally, did not think the application of electricity to their line of railway would be successful, but the question was one well worthy of consideration.

MORECAMBE ELECTRIC LIGHT AND POWER COMPANY.—The Directors report that the revenue account from November 16, 1892, to December 31, 1893, shows an expenditure of £1,361, and revenue £1,546, leaving a gross profit of £189, which is reduced by £92. 2s. for interest on borrowed capital, and bad debts £9. 3s., leaving a balance of £88, which the Directors recommend to be applied to the payment of a dividend of 2 per cent. per annum on the paid-up share capital.

MUNTZ'S METAL COMPANY.—The Directors of this Company recommend a final dividend at the rate of 15 per cent. per annum, making a dividend of 10 per cent. on the past year's working.

A. AND J. STEWART AND CLYDESDALE (LIMITED).—The Directors of this Company recommend a dividend at the rate of 7 per cent. per annum, the transfer of £10,000 to depreciation fund, carrying forward £8,169.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to allow £150,000 First Mortgage Debentures to be quoted in the Official List.

MEXICAN TELEGRAPHS.—It is stated that a syndicate of Mexican and American capitalists has been organised for the purpose of constructing a Pan-American telegraph line to extend along the Pacific coast from Victoria, British Columbia, to Santiago, Chili.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of the Company for the week ended February 23rd (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,181.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 825.—Vol. XXXII. FRIDAY, MARCH 9, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The action, " Muirhead *v.* the Commercial Cable Company," the hearing of which concluded at 10 o'clock on Wednesday night, after having occupied the attention of Mr. Justice Kennedy for seven days, contained several features of interest. The point at issue was briefly this: The Commercial Cable Company, a licensee under the Muirhead duplex telegraph patents, sought to show that it was exempt from payment of further royalties on the ground that an American patent, taken out in 1880 by Dr. Alexander Muirhead, and under which the Company was bound to pay royalties until 1897, had expired simultaneously with the English patent taken out in 1876 jointly by Mr. John Muirhead and Dr. Alexander Muirhead. By American law, an inventor who takes out a United States patent *after* a foreign one has his American patent limited by the duration of the shortest-lived foreign patent. The argument of the Cable Company was that the United States specification of 1880 was nothing more than a detailed description of one of the many methods of duplexing set forth in the English specification of 1876; hence the American patent, instead of running on until 1897, had *ipso facto* expired in 1891 with the English patent. The case thus gave rise to the somewhat unusual spectacle of an English court discussing an obscure point of American law, and of a patentee trying to show that he had not been anticipated by himself. In addition, the Court was treated to an interesting *résumé* of the early history of submarine duplexing; and last, but not least, the sum involved (£45,000) was by no means small, even when reckoned in English pounds sterling instead of American dollars.

The noble army of experts mustered in great force, and the Judge was ably instructed in the elements of electricity and the complexities of duplexing by Profs. Silvanus Thompson and John Hopkinson. The exact meaning of the term "rheostat" proved, indeed, somewhat of a stumbling block, and though the definitions, "a *readily* adjustable resistance," and then "a *continuously* adjustable resistance," were offered, it required a good deal of wearisome examination and cross-examination to make it clear that a rheostat was not necessarily a low-resistance apparatus. The army of experts is already dichotomous; better far that it should become trichotomous and give the Court the benefit of a portion of its learning from the bench instead of from the expert witness-box. A number of instruments were produced to illustrate the proceedings. Why should not instrument makers, on such occasions, hold a small exhibition of their wares? They would be much more intelligently appreciated than at *conversazioni*.

At the meeting of the City Commission of Sewers, last Tuesday, the recommendation of the Streets Committee that an electrical inspector should be appointed at a salary of £300 per annum was briskly discussed in regard to the amount of salary. It appears that while, on the one hand, the gas inspector to the Corporation received £400 a year, on the other hand Mr. Preece—"the greatest electrician of the day"—had advised that the salary of the electrical inspector should commence at only £200. It was argued by some members of the Commission that "electricians were now almost as plentiful as blackberries"—a sad analogy at a time when brambles are leafless and destitute of berries; and that "some electricians were without shoes owing to lack of employment." Ultimately it was decided to adopt the usual but inane process of compromising, the salary being fixed at £250. And a reliable man, fully competent to inspect 48 miles of electrically-lit streets in the wealthiest city in the world, is expected to be obtained for this pittance, because, forsooth, there are shoals of unreliable and incompetent men, falsely called electrical engineers, flooding the profession.

The Paper by Messrs. Barr and Phillips on the "Brightness of Light," which we publish this week, fully illustrates the difficulties met with in the accurate measurement of light. A number of ingenious methods, which have been proposed from time to time with the object of making optical measurements more reliable, are described. None of these efforts have, however, met with any real success. The fact is that no instrument can be found to replace the eye, simply because light is merely the effect of radiation on the optic nerves, and the law which governs the sensitiveness of the eye to light of various colours and intensities seems at present to be quite an arbitrary one. Perhaps the most striking example of this given in the Paper is shown in the curves of luminous and visual intensity shown in Fig. 2. Apparently the kind of light which is most efficient in making an object appear bright or luminous is not the kind of light which produces most effect in enabling the eye to perceive small print distinctly. But, paradoxical as this result may appear, it is not so striking as another fact which has been brought out recently by the researches of Capt. Abney and Gen. Festing. These experimenters found that, if two surfaces were illuminated to an equal

Digitized by Google

brightness by means of red and green light respectively, and if then the light falling on the surfaces was diminished in the same ratio for each, the two luminous patches no longer remained of the same brightness as judged by the eye. In fact, on reducing the red light to such an extent that the red patch was no longer appreciable, the green patch remained distinctly visible, in spite of the fact that the light in each case had been reduced in the same proportion. This shows the impossibility of getting any indicator to replace the eye in the judgment of illumination. In spite of colour difficulties often met with when comparing light, and in spite of the want of sensitiveness of the eye, it is necessary to rely on our powers of vision when different light sources have to be relatively estimated.

THE discussion on the photometry of search lights, which was started by a casual remark in our columns nearly six months ago, has been continued at intervals in the French electrical journals up till last week. Hitherto the matter has been dealt with from the theoretical side, and the mirror or lens being assumed to be theoretically perfect, and the source of light to be placed exactly in the focus, the theoretical rays behaved theoretically, and it was conclusively proved that certain theoretical measurements might be made. Over the initials "P. G." some more mathematical investigation of the subject is contributed to *L'Industrie Electrique*. The interesting theoretical fact is brought out that at very short distances, the illumination at a point on the axis is constant, but at greater distances the law of inverse squares is (theoretically) rigidly obeyed. Some experiments carried out by M. FERY at the optical laboratory of the École de Physique et de Chimie Industrielles at Paris are described. An achromatic lens, 78 cm. focal length and 7 cm. in diameter, was used; the source of light was a circular diaphragm 1·4 cm. diameter; and the distance of the photometer varied from 0·78 to 15·78 metres. The experiments so far confirmed the theory that, but for errors of 12 to 16 per cent., the illumination was constant up to about 4·28 metres, but the next reading at 5·28 metres yielded only 68 per cent. of the theoretical illumination, and at further distances was only 45 or 46 per cent. The explanation of these errors is probably simple, but if with all the appliances, adjustments, and refinements of an optical laboratory such discrepancies occur, what are we to expect from an ordinary search-light projector? Our original objection was, that a minute inaccuracy of adjustment of the arc would so alter the character of the beam that photometry would become useless, and that slight imperfections of the mirror would give rise to very great errors. The first of these difficulties, at all events, ought to be easily avoided in a laboratory, and the general result of these experiments confirm the views which we have put forward on previous occasions.

IN a report by M. COHN on artificial lighting, in *La Lumière Electrique*, a description is given of a reflector invented by Herr HRABOSKI for the uniform distribution of light. A dish or pan-shaped reflector is used in conjunction with a prismatic ring of glass. The sloping sides of the reflector subtend a zone of only about 30deg., the rays falling at a greater angle than 45deg. with the horizontal are intercepted and partly reflected by an opal shade hung below the lamp. The rays of less than 25deg. incidence fall directly on the reflector, and those between 25deg. and 45deg. are refracted by the prismatic ring, and are directed upon the reflecting zone. As this glass ring appears from the illustration to be from 14in. to 18in. diameter, a focussing lamp would be necessary. The arrangement appears to have been designed with some regard to optical theory, but the whole usefulness of the calculated curve of the reflector is at once defeated by painting it white. We very much doubt whether a mathematically-designed reflector, which, of course, must be of metal or silvered glass, would be worth using. The requirements of a whitened reflector, as we pointed out in connection with Mr. B. A. DOBSON's Paper on the lighting of workshops, are merely that it should be large, and should subtend a large angle to the light. Its form or curvature is quite inoperative, for it is the property of a dead white surface that light falling on it from any direction is always reflected in one and the same manner, the direction of greatest intensity being always normal to the surface.

THE agreement between the observed value for the voltage just sufficing for the decomposition of an alkaline salt, and that calculated from thermo-chemical data, which has been demonstrated by the researches of M. NOURISSON, described by Mr. BERTRAM BLOUNT a few weeks ago in this journal, has long been recognised, although not in the same sense of precision as at present. Claims of priority in this line of investigation were, therefore, to be expected, and a recent number of the *Comptes Rendus* contains two such communications. The first is by M. LE BLANC, whose name is well known in connection with electrolytic research, and who cites Papers of his own published in the *Zeitschrift für physikalische Chemie*. He quotes figures obtained by experiment with normal solutions of the chlorides, bromides, iodides, sulphates, and carbonates of the alkalies and alkaline earths, and of ammonium, the concordance with those of M. NOURISSON being generally good. Ammonium salts give rise to divergencies from the calculated values according to both M. LE BLANC and M. NOURISSON, such irregularity being readily intelligible on the grounds adduced in the article in *The Electrician* already referred to.

THE other claim of priority is one by M. BERTHELOT, whose work has an earlier date than that of either of his colleagues in the same field. The subject was dealt with by him in a memoir appearing in 1882, and printed in the *Annales de Chimie et de Physique*. This work owes nothing to the theoretical consideration of the actual mechanism of electrolysis, but rests solely on the comparison of the observed critical voltage and thermo-chemical data experimentally obtained. The concordance of the results of the two investigators is again good. Incidentally M. BERTHELOT points out that the salt selected for experiment should not yield an acid or a base as the main products of electrolysis, which are capable of oxidation or reduction under the conditions of the experiment. That even such a salt as an alkaline sulphate might fail to comply with this requirement on account of the comparative

Digitized by Google

ease with which persulphates are formed by electrolysis was indicated in Mr. BLOUNT'S article, the accuracy of agreement between calculated and observed values being impaired by want of knowledge of the total chemical energy involved. The following table of comparison will be found interesting :—

	Potassium chloride.	Potassium bromide.	Potassium iodide.
M. Berthelot (1882)...	1·98 volt	1·73	1·16

COMMENTING on the circumstances attending the lamentable explosion of a steam pipe on the German cruiser "Brandenburg," the *Daily Chronicle* says that "The fault appears to lie with a new copper steam pipe, which gave way with a pressure of 7,200 horse-power, when a previous pipe had sustained a pressure equal to 10,000 horse-power." This enterprising newspaper is gradually but surely evolving an entirely new system of scientific units, which, with commendable modesty, it is publishing by instalments. The amount of editorial brain-cudgelling which must have preceded this, the latest addition to its stock, must have been prodigious. The value of expressing everything in terms of the *horse-power* ought to be appreciated by the engineer. The only question is—Can it be done? Still, with the aid of the "newspaper scientist" we ought not to despair of its ultimate attainment.

The Differential System of Charges.—At a meeting of the Edinburgh Corporation Electric Lighting Committee it was agreed that the charge for electricity should be 6d. per unit for lighting, and 3½d. per unit for motors.

Proposed Electric Tramways in Cork.—At the sitting of the Judicial Committee of the Privy Council in Dublin on Wednesday a scheme was passed for the construction of a line of electric tramways in Cork to connect the new station with the Muskerry Railway Station.

A Proposed Floating Electric Lighting Station.—A curious proposal has recently been made with regard to the prospective electric lighting of St. Olave's. It has been suggested that, in the event of no land site being available for the generating plant, this should be placed on a barge moored on the Thames.

Cable Interruptions and Repairs :—

Institution of Civil Engineers.—At the monthly ballot of the Institution of Civil Engineers, held on Tuesday last, Mr. H. Faraday Proctor and Mr. Charles P. Sparks were elected Associate-Members of the Institution. Thirty-seven other candidates were elected to this grade; and two Members were elected.

Fire in an Accumulator House.—On Saturday morning a fire broke out in the electrical accumulator house at Crewe works. The works fire brigade were quickly on the spot, and checked the progress of the flames. Considerable damage was done to the building, and nearly all the acid tanks were broken by the heat. The origin of the fire is unknown.

The Electrical Trades' Union.—A deputation from the London Trades Council and the Electrical Trades' Union will shortly wait upon the Postmaster-General to lay before him the conditions of labour and rates of pay in the instrument department of the General Post Office. The pay there, it is stated, is much below that ruling in private firms.

Electro-Therapeutics.—According to a German contemporary Dr. Helbing has been successful in twenty cases in healing people of the frozen nose, the treatment being to apply both electrodes to opposite sides of the nose, and to pass a moderately strong current for five or ten minutes, moving the electrodes about; the immediate result is a reddening of the tissues, which may last several days; in some cases ten to fifteen applications are necessary.

The University of London.—Notice has been given that on Wednesday, April 25th next, the Senate of the University of London will elect examiners in various departments, including the department of experimental physics. Two examiners will be elected in this department, at a salary of £210 per annum each; and the present examiners are eligible for re-election. Candidates must send in their names to the Registrar, with any attestation of their qualifications they may think desirable, on or before Tuesday, March 27th.

A Hindu Telephone.—It is reported that an English officer, named Harrington, has discovered in India a working telephone between the two temples at Pauj, about a mile apart. The system is said to have been in operation at Pauj for over 2,000 years. In this connection we may observe that Egyptologists have found unmistakable evidence of wire communications between some of the temples of the earlier Egyptian dynasties; but whether these served a telegraphic, telephonic or other purpose is not certain.

Board of Trade Electric Traction Conference.—The name of Mr. Sydney Morse was accidentally omitted from the list of the representatives at this Conference. Mr. Morse was requested to attend on behalf of the Traction Committee of the Electrical Trade Section of the London Chamber of Commerce, and, as the only legal adviser on the side of electrical traction, his services, as our report of the proceedings showed, were of great value. Mr. J. Swinburne was another representative of this Committee, but owing to pressure of other work was unable to attend.

Telegraph Construction in South Africa.—Intelligence has been received at Durban that, owing to the action of the Portuguese in obstructing the building of the telegraph line between the British sphere and Tete on the Zambesi, which we referred to in our last issue, the commander of the British stern-wheel gunboat "Mosquito" landed a party at Tete and fired upon the Portuguese. The Governor of Quilimane is hurrying to the scene with Portuguese gunboats and troops. The commander of the "Mosquito" is believed to have asked for reinforcements.

A Cold Galvanising Process.—It is said that several shipbuilding firms have adopted the cold process of galvanising sheet iron, and are erecting tanks capable of dealing with plates as large as 25ft. in length. This process was first introduced into practical use at the works of Messrs. Laird Bros., of Birkenhead. It is claimed by the inventor, Mr. Cowper-Coles, that a greater adhesion of the zinc, as well as a greater strength and durability in the covered plate, can be obtained by the cold process than by the hot process formerly and more generally in use. To quicken the process and retain a smooth surface, an electric current is passed through the pickling tank.

An Electric Parcel Van.—Trial was made last Friday afternoon of an electric parcel van, designed by Mr. W. C. Bersey, and built by Messrs. E. J. Clubbe and Co. The interior of the van is left free for goods. Power is derived from thirty-six storage cells, which are carried under the body of the van in a special box, and so arranged that they may be changed in two minutes. With his left hand the driver, by means of a single switch, regulates the speed, which, if necessary, may be as high as fifteen miles an hour. The right hand is free to turn a steering-wheel, which is provided with a pointer, indicating the direction in which the vehicle is going. As the steering-gear has ball-bearings, the conveyance is under perfect control with a minimum of effort.

Lightning.—On the estate of Glencarse, belonging to Mr. T. W. Greig, much damage was done to a large ash tree on

Digitized by Google

Tuesday week by a flash of lightning. The tree was struck and broken over 20ft. from the ground, and the branches were broken and blown about in all directions. The trunk of the tree was split from top to bottom. Houses stand within 20 yards of the tree, but fortunately no damage was done to them.——The Norwegian barque "Saga," now at Greenock, from Mobile, while coming up the Channel last Friday night was struck by lightning, and the captain's cabin set on fire. Books and charts were destroyed, but none of the crew were injured. A violent gale was raging at the time.

The Pacific Cable.—At the Australasian Postal Conference, at Wellington, the various schemes which have been formulated for laying a cable to connect Australia with North America were discussed, and the Conference declared itself in favour of a line starting at Bundaberg, in Queensland, and proceeding thence to Samoa, Fanning Island, Honolulu, and Vancouver. This was regarded as the most feasible commercial route for a cable under the Pacific, and as being likely to enlist the support of Great Britain, Canada, the United States, Germany, and France. A Washington telegram, dated March 7th, states that the officials of the Post Office department, referring to the proposals made at the Postal and Telegraph Conference at Wellington, declare that it would be impossible for the United States Government to support a Pacific cable which did not touch United States soil.

The Electrical Purification of Oil.—In a recent number of the *Comptes Rendus* M. A. L. Levat describes some experiments made by him with a view to testing the efficacy of the electrical purification of oil. He placed a column of olive oil of inferior quality, bitter in taste and clouded in colour, in contact with the negative electrode of a voltameter which was in circuit with a small Siemens magneto machine. After electrolysis the oil was clarified and sweet tasting. In all, twenty samples of oil from various sources were hydrogenated, in every case with marked improvement in taste and colour. A series of experiments were also carried out on lubricating oils of bad quality, having at least 5 per cent. of free acid. Their acidity always diminished by at least 20 per cent., and by submitting the oil to a second electrolysis the acidity was diminished by 30 per cent. M. Levat states that he was unable to diminish it further.

Curious Phenomenon attending Silver Electro-Deposition. Those who have had occasion to measure an electric current by the deposition of silver on a platinum bowl as cathode have probably, says *Nature*, occasionally noticed the very regular manner in which the silver is deposited in radial lines. This appearance is particularly noticeable on the sides of the bowl, and when a somewhat strong solution of silver nitrate is employed. Herr U. Behn has conducted an elaborate series of experiments with a view to ascertaining the cause of this regular deposition, and has examined the effect on the deposit produced by the concentration of the solution, the current density, and the potential difference between the anode and cathode. He finds that in the electrolysis of silver nitrate the effect is best obtained with a concentrated solution of the salt, and when the current density at the cathode is small. An increase in the temperature of the voltameter is found to facilitate the formation of the ridges, while, on the other hand, the value of the electromotive force employed seems to exert no influence.

The Recent Sun Spot.—*Nature* states that the recent sun spot, about which so much daily-paper fuss was made, was after all a comparatively small affair. It was first seen in the south-east quadrant on February 19th, and probably passed off the visible disc about March 2nd. It has been somewhat remarkable for its relatively large penumbra and the scattered character of the umbra; a very distinct nucleus was also observed. In the course of an interview, Mr. Maunder stated that the spot was at a maximum on February 20th, when it was about 48,000 by 46,000 miles, and the area 1,870 millions of square miles. It was, therefore, much smaller than the great spot of February, 1892. Though the magnetic disturbances have not been so great as in the case of the 1892 spot, a marked effect on the Greenwich recording magnets was noticed at 3.15 p.m. on February 20, the disturbance lasting about 27 hours. After an interval of about 24 hours, another and more intense storm commenced, and reached a maximum at 3 p.m. on February 23rd. In the case of the spot of February, 1892, the violent magnetic storms occurred *after* the spot had passed the central meridian; but in the present instance, the disturbances seem to have preceded the central transit of the spot.

The Velocity and Shape of Steam Jets—M. H. Parenty has been investigating the forms of steam jets from various orifices, and has published his results in the last number of the *Comptes Rendus*. The diagrams accompanying the Paper, in which regions of different pressures are shaded differently, exhibit some curious fluctuations, which may be described as a series of nodes and ventral segments proceeding outwards from the orifice. These fluctuations are due to the interference between the outgoing waves of steam pressure and those reflected back by the air. In the case of a convergent elliptical orifice of 13deg. there nodes were found with pressures of 115, 165 and 138 c.m. respectively, that at the orifice being 285 c.m. or 3·75 atmospheres. All the nodes occurred within 2 c.m. of the orifice. They were found by means of an air manometer provided with very finely-drawn glass tubes. It appears that the position and value of the nodes or condensations depend upon the difference of pressure between the boiler and the atmosphere and the form of the orifice. At very high pressures the jet assumes an approximately paraboloidal shape, such as would be assumed by a liquid jet falling upon a disc of the size of the orifice. A further conclusion reached by M. Parenty is that the highest attainable velocity of efflux is the limiting velocity of sound in the medium concerned.

The Storage Battery in Telephone Exchange Work.—Amongst the recent improvements in the St. Louis Telephone Exchange service is the substitution of storage batteries and motor-generators for the old primary batteries. The central exchange of the Bell Telephone Company of Missouri, at St. Louis, operates about 4,000 telephones. It is also connected to exchanges in eight neighbouring towns, the most distant one being 24 miles. The Law system is used. The plant at the central office consists of a six kilowatt motor-generator and 90 350-ampere-hour cells of the Julien type. A portion of the current, supplied by 42 cells, accomplishes the work formerly done by 700 cells of gravity battery, which were used for telephone calls only. In addition to their main work, the storage battery plant supplies current to about 60 16-c.p. lamps for lighting the battery room, supply rooms and exchange, and to 100 1-c.p. lamps, using about one-fourth of an ampere and 12 volts each, and the relays of the signal system. The plant at the Lindell-avenue branch office consists of a 2½-kilowatt motor-generator and 50 150-ampere-hour cells of the Ford-Washburn type, which supplies current for all uses. The motor-generators are standard 500-volt motors and 110-volt shunt dynamos of the C. and C. make, directly coupled. The motors at both stations receive their supply from the 500-volt street mains. At St. Louis, also, small 1-c.p. signal glow lamps are lighted up whenever an interchange wire is in use. Another custom is as follows:—Whenever a subscriber calls and the operator finds the connection required busy, the subscriber calling receives a signal of four little musical toots, which is accomplished by a buzzer being momentarily introduced into the subscriber's circuit. This idea is supposed to be a much more agreeable signal to the disappointed one calling than the nervous tap of the bell which has been the usual response. When a customer has finished a conversation and neglects to call off, the bell of his telephone taps at intervals of two seconds until the operator receives the proper signal. The periodic ringing of the bell is accomplished by connecting the subscriber to a special battery circuit which is connected through an interrupter of special design. It consists of a pendulum such as is seen in large clocks, which carries a contact of non-arcing form to make a circuit at each complete swing of the pendulum. These momentary impulses of current pass through an electro-magnet which attracts an armature on the pendulum to keep up the motion. The circuit is then taken to each operator's table and is available at all times for attaching to the forgetful subscriber's who fails to properly disconnect.

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(Continued from page 446.)

Variation of Pressure in Conductors having Self-Induction and Capacity.

The next point to consider is the effect of variations of load on the drop. A bank of incandescent lamps is practically a non-inductive load, and the drop can be estimated without difficulty from the known ohmic resistance and the small increase of resistance in the mains due to the frequency. But if the load be partly or entirely composed of arc lamps or motors, or other devices containing self-induction, then there will be a further drop in the pressure due to a counter electromotive force, which will vary in magnitude with the current. The difficulty is met to some extent in lighting stations by running separate circuits for arc lamps. Also motors have not been used to any appreciable extent in alternate current circuits, and when used are run chiefly by day when the lighting work is comparatively unimportant. And in the few cases where power work is sufficiently large to warrant the expense, separate circuits have been set apart for the motors. The author believes that most of the Continental stations that have tried the dual load have ultimately found it advisable to use separate circuits (at any rate for the larger motors). For although a varying pressure may be unimportant, perhaps, as regards motors, it is a serious matter with arc lamps, and still more so with incandescent lamps. The effect of capacity in a circuit is precisely the opposite to that of self-induction, the condenser electromotive force being phasially 180deg. distant from the electromotive force of self-induction. And since each of these effects are functions of the circuit they may under certain conditions be made to counter-balance each other to some extent. The capacity effect is found in concentric conductors and in single or concentric mains armoured by continuous metallic sheathing, and it is worthy of consideration whether the latter are not of special use for circuits supplying alternate currents to inductive loads. At any rate they should tend to cause a smaller drop of pressure than ordinary copper conductors in an inductive circuit.

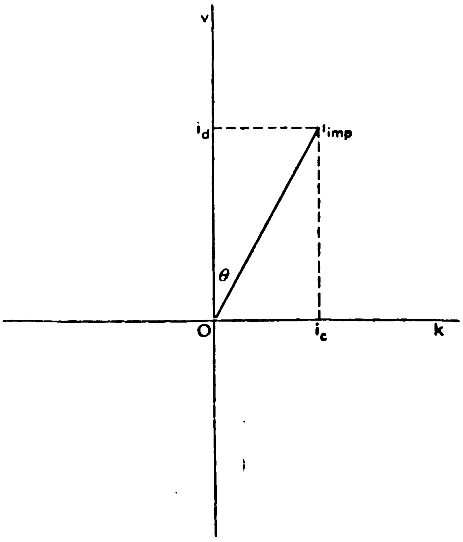

FIG. 84.—Showing the effect of capacity in an alternate-current circuit. O V is the impressed E.M.F.; O i_d, watt current; O i_{imp}, impressed current; and O i_c, condenser current; θ, angle by which resultant current leads impressed pressure.

Some idea of the order of these effects in the mains may be gathered from the following:—

First, consider a concentric conductor carrying an alternate current, and assume that the alternator and the motors have neither self-induction nor capacity. Let the terminal pressure of the alternator be v. Now the capacity

$$C = \frac{K d}{2 \log_e \frac{R_1}{R_2}} \cdot \frac{1}{9 \times 10^5} \text{ microfarads}, \quad . \quad . \quad . \quad (48)$$

d being the thickness of the dielectric between the two conductors, R_1 the radius of the inside of the outer tube, R_2 the radius of the inner conductor, and K the coefficient of specific inductive capacity of the dielectric in C.G.S. units. And the condenser current in practical units is

$$i_c = 2\pi \sim \text{VC } 10^{-6} \quad . \quad . \quad . \quad . \quad (49)$$

i_c and V being effective values.

The condenser current is, as already stated, a quarter period in advance of the pressure. In Fig. 84, let O V represent V. Then Oi_c represents i_c, Oi_d is the dynamic current, and, of course is in phase with Ov. Through i_d parallel to Oi_c, draw $i_d i_{imp}$; At i_c in O K erect the perpendicular $i_c\, i_{imp}$, meeting $i_d\, i_{imp}$ at i_{imp}; and join O i_{imp}. Then O i_{imp} is the current that must be supplied by the alternator, and it is in advance of the impressed terminal pressure by an angle θ.

Fig. 85 is constructed in a similar way, and shows the lag ϕ due to inductance.

The result of capacity, then, is to cause the impressed current to lead the line pressure, while inductance causes it to lag. This phase-difference introduces several important results. If it be positive, the terminal pressure of the generator will be raised, because the armature reactions will then tend to strengthen the field. This is seen to be the case by considering that the maximum pressure obtains when the armature coils are midway between the field poles; and therefore, if the maximum value of the current obtain before this position is reached, the coils will help to magnetise the field magnets; and, on the contrary, if by reason of self-induction the current lags in phase, it will help to decrease the magnetism.

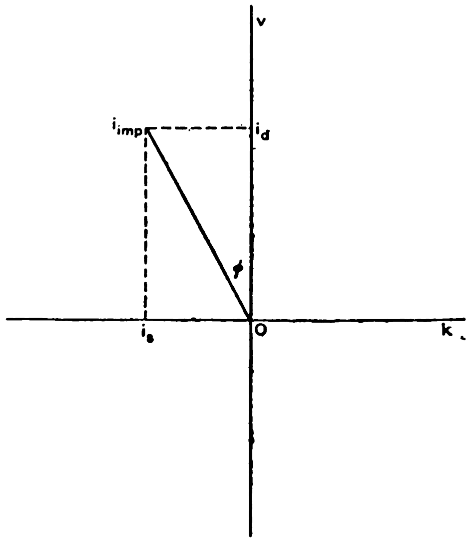

FIG. 85.—Showing the effect of self-induction in an alternate-current circuit. O V is the impressed E.M.F.; O i_d, the dynamic current; O i_{imp}, the impressed current; and O i_s, the current due to the E.M.F. of self-induction. ϕ is angle which impressed current lags behind impressed pressure.

The effects of self-induction and capacity with concentric cables may be shown graphically, when the constants of the circuit are known, by combining the diagrams in the preceding figures. And by suitable approximations the effects for a complete power plant may be estimated in the same manner. The procedure is indicated in Fig. 86.

O C is the maximum value of the difference of pressure between the condenser plates $= \dfrac{i}{C\, 2\pi \sim}$

O L is the maximum value of the counter pressure $= L i 2\pi \sim$. O R is the resultant pressure which sends the current i through the inductive circuit of impedance $\sqrt{R^2 + L^2 4\pi^2 \sim^2}$. The pressure at the terminals of the condenser is H V by the construction (for R H = O L, and R V = O C − O L. Then O V represents in phase and magnitude the impressed pressure required to maintain the current through the condenser.

The condenser effect is a maximum when the angle H O V is a right angle; or H V the condenser pressure has a maximum ratio to O V the impressed pressure when this is the case.

In practice, with the insulations commonly used and the sizes of conductors most in vogue, the capacity of concentric mains between the inner and outer conductors appears to be about one-third of a microfarad per mile run. But the effect is far more serious between the outer conductor and the earth, being nearly ten times greater. It is, therefore, important with high frequencies and high pressures to take into consideration the capacity effects as well as the self-induction.

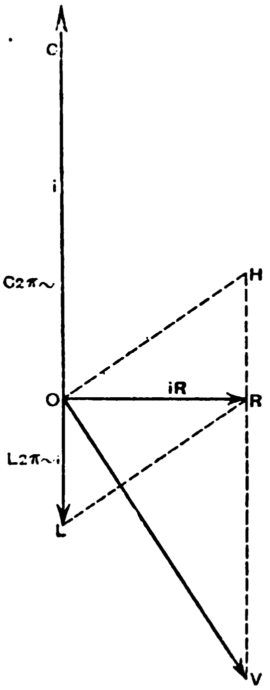

FIG. 86.—Showing the Effect of Capacity and Self-induction in a Circuit.

Concentric cables are used to prevent periodic currents of high frequency influencing telephones and telegraph circuits by induction. They are a remedy for these troubles undoubtedly, but they may cause other difficulties.

As already pointed out, self-induction reduces the useful work of a given plant, but it does not directly waste much power. Capacity, on the other hand, reduces the useful work chiefly by absorbing power.

Compensating for Drop of Pressure in Conductors.

There are several methods in use at present for compensating the variations of pressure in the feeders or in the transmission mains. The most common consists in simply adjusting the

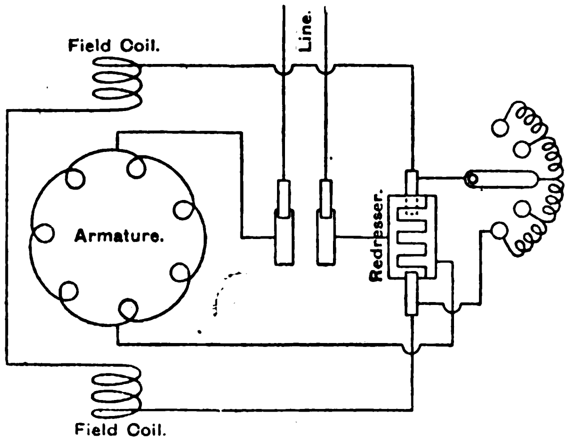

FIG. 87.—Thomson-Houston Method of Compounding Alternators.

excitation by hand or automatically, the generators being separately excited; another is accomplished by compounding the alternators in a manner similar to that adopted with dynamos, the alternators being either self-exciting or else partly self-exciting and partly separately excited.

Hand regulation by a resistance in series with the field-coil circuit is easily understood, and there is no need to make any special reference to automatic devices whose function is simply to vary the resistance of the exciting circuit.

The Brush Corporation, Messrs. Ganz and Co., Messrs. Goolden and Co., and others, make automatic regulators of this description, and the author has spent much time in designing similar devices, but in his opinion they cannot be regarded as complete successes, and certainly are not adapted for use in power plants where there is no skilled supervision. The compound winding, however, is a practical device. By means of it alternators can be made to compensate for any predetermined drop, and therefore meet most of the regulation difficulties in the feeders. The arrangement adopted by the Thomson-Houston Company is to partly excite the field from a dynamo with a steady current and to provide a variable excitation by redressing a portion of the main current and passing it through a pair of coils opposite to each other or else through coils on each of the field poles. It is clear that since the armature current is redressed that the excitation due to it will be proportionate to the load.

The arrangement is shown in Fig. 87. The "redresser" consists of two circular gun metal castings having each half as many projections as there are pole-pieces in the field; both being insulated. One of these is connected to one of the collecting rings and the other is joined to the free end of the armature coils as shown. Two brushes resting on projections belonging to opposite rings of the redresser form the terminals of the exciting circuit. To reduce sparking at the instant of short-circuiting the field coils when the brushes rest on the same rings, a suitable resistance is placed in shunt to the field, and this serves in addition to control the proportion of current in the exciting coils, and therefore to vary the compounding

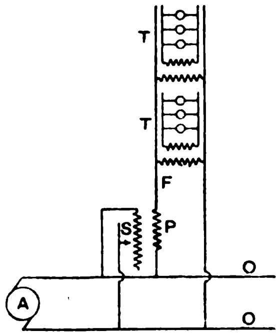

Fig. 88.—Kapp's Method of Regulating the Drop of Pressure at the End of a Feeder.

within the limits of the design. This is a very complete and convenient device. It is characteristic of the methods generally adopted by Ganz and others. Alternators thus compounded will not work parallel.

Another very simple plan is to place the primary of a suitable transformer in series with the feeders, and to excite the compound coils from its secondary current, redressed. Since this current is proportionate to the armature current, it is clear that the compounding can be arranged to any slope of characteristic.

A device patented by Mr. Kapp is interesting. It is shown in Fig. 88.

One coil, P, of a small transformer is placed in series with the feeder, and the other coil, S, is coupled across the station mains. By inserting more or less of the turns of the coil S into circuit by a shifting contact, a few auxiliary volts are put into the feeder by the inductive action of the shunt-coil. This regulator may be designed to add a sufficient number of volts to compensate for any desired drop. It may be applied to each feeder independently, although all the circuits be working off one alternator. This is a distinct advantage, and makes it a most convenient detail for power plants. The Westinghouse Company use a similar device, which they call a "booster."

Determination of Pressure at the End of Feeders.

The pressure at the termination of the alternate-current feeders is read by means of two transformers, without the aid

Digitized by Google

of pressure wires run back to the station. The general arrangement is as follows :—The voltmeter is in series with the secondary circuits of two transformers, one of which has its primary in series with the feeder, and the other of which has its primary as a shunt across the feeder. It is illustrated in Fig. 89.

The pressures of the two transformers are opposed to each other. The secondary pressure of the transformer in shunt is proportional to the station omnibus pressure, V ; and that of the transformer in series to the primary current strength i_m, and therefore to i_m R, if the resistance be constant. The voltmeter will consequently read proportionately to V—i_m R, which is the expression for the pressure at the far end of the feeder. This principle with important modifications is

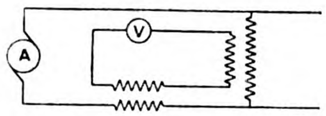

FIG. 89.—Diagram of Station Voltmeter Connections for Reading Pressure at the far end of Feeder.

employed by Messrs. Ganz and Co. Its application is shown in diagram in Fig. 90, the adjustable resistance in the exciter circuit being also shown. The alternator is shown at A, and the feeders at L_1 L_2 ; the shunt transformer at T_1 and the series transformer at T_2. The secondary circuit of T_1 is closed through the solenoid of the regulator S, the resistances T_3, R_1 and R_2. The secondary of T_2 is closed through the resistance R_2. The transformers are joined up so that their electromotive forces are in opposition as regards producing a current in the solenoid S. The terminal pressure of T_1 is evidently proportionate to the station pressure. The difference of pressure between the points *a* and *b*, the terminals of R_2, will be proportionate to the feeder current ; and so the pressure between the points *e* and *f* will be equal to V – i_m R, the pressure at the termination of the feeders. The intensity of the current in the solenoid circuit will determine the excitation, and hence the

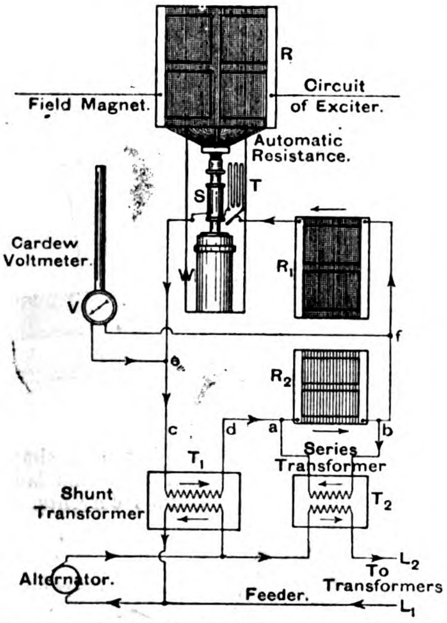

FIG. 90.—Ganz and Co.'s Method of Compensating for Drop in Feeders.

pressure at the sub-station can be kept constant for variation of drop. It will be seen that a Cardew voltmeter is used to read the primary pressure. This is possible by a suitable ratio of conversion in the transformers. It will be evident that these methods of reading the sub-station pressure are only applicable when the virtual resistance of the feeders is practically constant or varies according to some easily determined law, in which case the voltmeter can be specially calibrated to include these effects.

(*To be continued.*)

A NEW ALTERNATOR.

We are enabled to give, in this number, some diagrams and description of a new alternator which has recently been brought out by the Compagnie de l'Industrie Électrique, of Geneva.

In this alternator, the use of stationary windings is combined with the principle of the single inductor, all the poles on one side of the armature having the same polarity. This arrange-

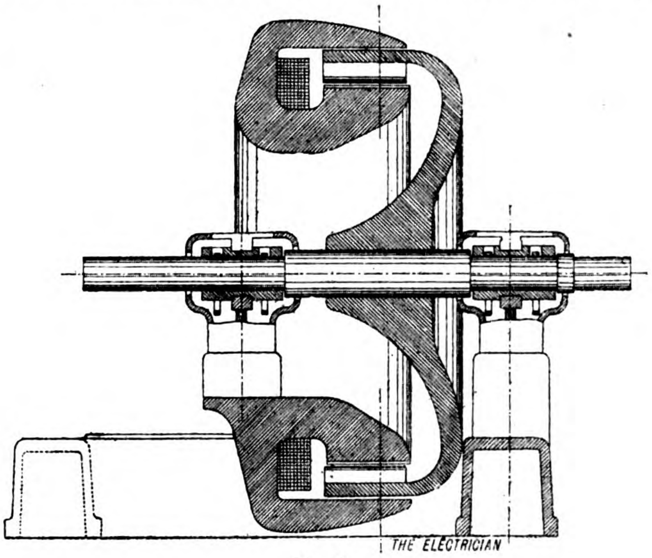

FIG. 1.

ment suppresses completely magnetic leakage, so detrimental when adjoining poles have different polarities. The alternator consists of the following parts, which are represented in the longitudinal section in Fig. 1. Firstly, a circular casting of steel, forming altogether the inductor poles and yoke ; the section of which somewhat resembles a pair of U's placed sideways, one on either side of the shaft and at some little distance from it. To be more exact, this casting is an annulus which is so flanged as to have everywhere a U-shaped section, forming an annular channel. At the bottom of this channel lie the

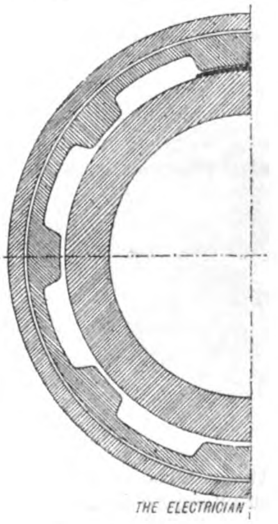

FIG. 2.

magnet windings, which are seen in section a little to the left of the centre in Fig. 1. These windings are built up of several parallel bobbins, placed at some distance apart to ensure ventilation ; and they are wound with bare copper strip. Upon the face of the inner side of the channel, near the lip, and at a place where the casting has been machined to a true surface, the armature windings are fixed, in a series of flat thin coils. These coils are indicated in Fig. 1 by close parallel lines ; and one of them is shown in Fig 2, at the top, as a thickening of the lips. Between the two lips of the annular channel there

Digitized by Google

revolves a toothed ring, formed by the flanged end of a second annular casting, which is nested into the gap in the first one. This second casting, which is also of steel, is keyed to the main spindle of the machine. The number of teeth is fixed by the number of alternations per second required, and by the speed of the alternator. The number of armature coils is always twice the number of teeth. The transverse section, showing the inner and outer lips of the U-channel, with the notched ring intermediate between them, is shown in Fig. 2. In this figure one armature coil is also shown, there being in actual fact one such coil under every notch and one under every interspace. The armature conductors are made of stranded copper, to prevent eddy-current induction. It will

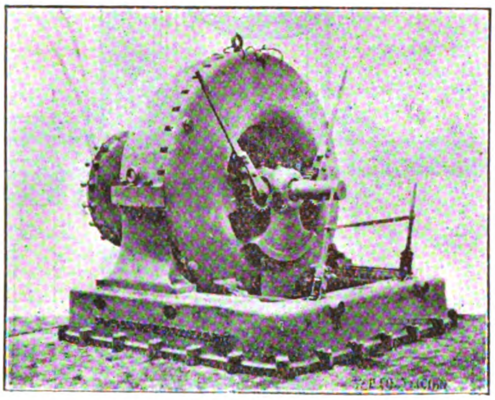

FIG. 3.

be seen that the only moving parts are the shaft and the cast-steel notched ring. On this account it is possible to have a very high peripheral speed, and the mechanical strains on the coils are entirely obviated.

Owing to the small air-gap and also principally to the use of the single inductor system, the power absorbed for the excitation, even with a very small weight of copper, is trifling and varies very little between no load and full load. In practice, with 275 kilowatts alternators, the excitation at full load absorbs three-tenths per cent. of the output of the alternator, and the increase of current between no load and full load is under 20 per cent. For equal weights of copper on the inductors and

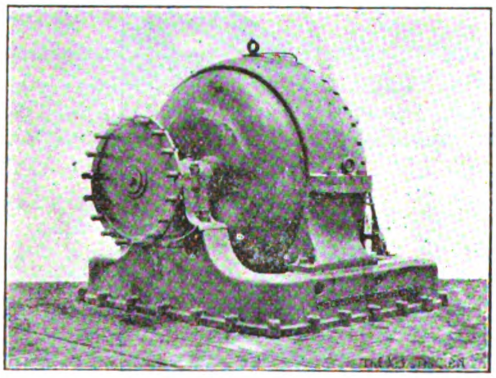

FIG. 4.

for equal powers, this alternator-inductor is said to absorb for its excitation about one-sixth of the energy required for this purpose by alternate poles alternators. The internal resistance is very small owing to the high magnetic densities used. It is possible to use conductors of large sectional area with relatively small-size machines. The C^2R losses are thus small, the armature self-induction weak and the machines easily work in parallel.

Some experiments have been made with a view to ascertaining this matter, on the same lines as the trials made by Mr. Mordey two years ago. The two alternators under trial were driven separately, one by a turbine and the other one, at will, by a turbine or by a steam engine.

During the first trial, at no load, each alternator driven at the same speed was excited to produce equal electromotive forces, and when in step, as shown by the synchroniser, they were connected in parallel without any difficulty. Then the valve of one of the turbines was gradually closed, and a compensating current passed from one of the alternators to the other, maintaining the speed constant by driving as a motor the alternator tending to lag behind the other, its motor being no longer able to maintain the previous speed. On the valve being completely closed, the alternator acting as a synchronous motor was driving the turbine, the machines keeping in step perfectly well. In the second experiment, the steam engine was substituted for one of the turbines, with the same results. For the third trial, still without load, the alternators were differently excited for the purpose of getting different voltages, the parallelling of the machine was easily done, the resulting electromotive force being one-half of the sum of the electromotive forces of each machine. Lastly, the load was put on the machines, the connecting up in parallel being as easy as before; then the current of one was gradually brought to zero, and the two alternators could be connected and disconnected without any effect on the external circuit.

To complete these trials, it would have been well to try the parallel coupling of the alternators without using the synchroniser. It is very probable, from the other results, that the coupling would have taken place as before, a very large current passing from the leading to the lagging machine, owing to the very small armature self-induction. Thus, these alternators allow the parallel working, even under trying conditions, and it is not necessary to use artificial loads. A right and left elevation of the machine are shown in Figs. 3 and 4 respectively.

THE "DOT" ARC LAMP FOR OPTICAL LANTERNS.

The arc lamp shown in the accompanying illustration has been specially designed by Mr. F. J. Borland, of Leeds, to fit into any optical lantern in the place of an ordinary limelight without any

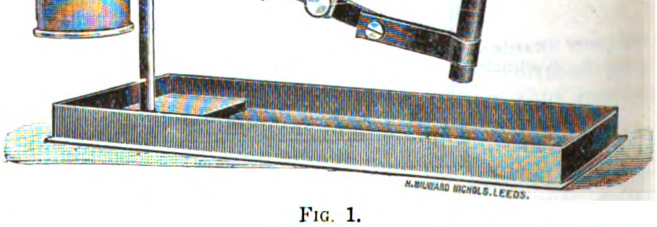

FIG. 1.

alteration. The construction of the lamp is simple, and the working is automatic. It is claimed that this lamp will work equally well on alternate or continuous currents. There is no

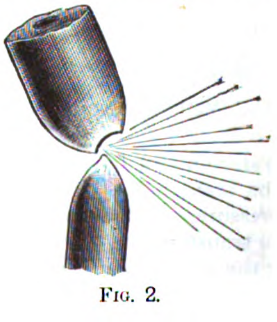

FIG. 2.

brake or mechanism, and the arc is self-focussing. These lamps have been recently used to replace limelights at the Theatre Royal at Preston. The cost is, of course, considerably less than that of limelight.

DER VERBAND DER ELEKTROTECHNIKER DEUTSCHLANDS.

The following is derived from the last number of the *Elektrotechnische Rundschau.* :—

At the meeting of the Committee of Management of the "Verband der Elektrotechniker Deutschlands" the following agreement with Mr. Gisbert Kapp came under consideration, and was adopted by 19 votes to 8, subject to the approval of the annual general meeting :—

"The following agreement is made between Mr. Gisbert Kapp on the one hand and the Verband der Elektrotechniker Deutschlands on the other hand.

"§ 1. Mr. Kapp undertakes from July 1, 1894, the Directorship of the office of the Union, with the title of General Secretary. . . . . His duty as manager will be to carry into execution the resolutions of the Managing Committee and the annual general meeting, being empowered, on the other hand, to order and rule the business of the office on his own responsibility, according to the general sense of the instructions given him by the Council. He will also undertake the duty of acting as editor of the *Proceedings* (Journal) of the Union according to the terms of the agreement with the publisher.

"§ 2. Mr. Kapp will receive a salary of 20,000 marks (£1,000) per annum, payable monthly ; and, in addition, one quarter of the surplus of income over expenditure in any year (if any). In calculating this surplus, the salary of the General Secretary on the one hand, and the contributions of the guarantors on the other, shall be omitted. . . . . .

"§ 3. With the exceptions described in this paragraph below, Mr. Kapp will devote his whole activity [Thätigkeit] exclusively to the Union, and he is especially not permitted, even gratuitously, to give advice in technical matters, or to write for the papers ; but he is to be allowed, so far as his work for the Union is not interfered with, to take out and deal with Patents in foreign countries, and to make agreements with foreign firms as regards licences for their use. In so far as Mr. Kapp takes out Patents in foreign countries, he is entitled also to take out patents in Germany under the following conditions :—

"The commercial use of the German Patents shall belong entirely to the Union during the existence of this contract." The Union is obliged to grant licences to its members on reasonable terms, the proceeds to go to the Union funds, and *may* give Mr. Kapp a share of such royalties.

"Mr. Kapp is entitled to continue any licences granted to foreign firms existing on July 1, 1894 ; and he is also permitted to publish books and to conclude contracts with regard to their publication ; and to lecture for fees in public schools.

"§ 4. The contract lasts five years, till June 30, 1899 ; and holds each time for a further period of two years at a time, if six months' notice of determination be not given. . . . . .

"§ 5. The Union is to give Mr. Kapp all necessary assistance, and office room, and to pay travelling expenses.

"§ 6. The Funds of the Union not being at present high enough to pay the General Secretary, a certain number of members guarantee his salary.

"§ 7. Mr. Kapp undertakes to take up his residence in Berlin, or in a neighbouring suburb. . . .

"§ 8. The Council is allowed to hand over financial business to the general office, and exercise the right of superintendence."

A further agreement between the Verband der Elektrotechniker Deutschlands and the publishing houses of J. Springer and R. Oldenbourg relates to the arrangements for constituting the *Elektrotechnische Zeitschrift* the official organ of the Union, having two editors, one appointed by the Union and one by the publishers and makes arrangements for sharing the profits of technical publications issued by these houses. This agreement was adopted *nem. con.*

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, March 9th.

PHYSICAL SOCIETY.

5 p.m. The following Paper will be read : "Calculating Machines, and especially a new Harmonic Analyser," by Prof. O. Henrici, F.R.S. Mr. H. Wilde, F.R.S. will exhibit his Magnetarium next meeting.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Ordinary Meeting at the Westminster Palace Hotel, Victoria-street. The following Paper will be read : "The Design, Construction, and Working of Boilers for Locomotive Engines," by Mr. G. Frank Burtt.

ROYAL INSTITUTION.

9 p.m. Evening Discourse : "The Making of a Modern Fleet," by William H. White, C.B., F.R.S.

SATURDAY, March 10th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture on "Light," with special reference to the Optical Discoveries of Newton, by the Rt. Hon. Lord Rayleigh, F.R.S.

MONDAY, March 12th.

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

7 p.m. Council Meeting at the Palatine Hotel, Hunt's Bank, Manchester.

8 p.m. Ordinary General Meeting at the Palatine Hotel, Hunt's Bank, Manchester. The following Papers will be read : (1) "Notes on Designing a System of Underground Electric Light Mains," by John H. Rider. (2) "The Various Systems of Underground Mains and Methods of Laying Same," by S. V. Clirehugh.

TUESDAY, March 13th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be further discussed : (1) "The Liverpool Overhead Railway," by J. H. Greathead and Francis Fox, M.M.Inst.C.E. ; (2) "The Electrical Equipment of the Liverpool Overhead Railway," by Thomas Parker, M.Inst.C.E. The following Paper will also be read (time permitting) : "The Prevention and Detection of Waste of Water," by Ernest Collins, M.Inst.C.E. ; to be followed by a reception by the President and Council.

WEDNESDAY, March 14th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. The following Paper will be read : "The Fountain Air Brush," by Charles Burdick.

FRIDAY, March 16th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse : "The Scientific Work of Tyndall," by the Rt. Hon. Lord Rayleigh, F.R.S.

SATURDAY, March 17th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture on "Light," with special reference to the Optical Discoveries of Newton, by the Rt. Hon. Lord Rayleigh, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Steam Piping.—A Paper on "Steam Piping and Efficiency of Steam Plants," by W. A. Pike, was recently read before the American Society of Mechanical Engineers. The author thought sufficient attention had not been paid to this matter by engineers. He considered poorly contrived piping was the cause, in many cases, why the efficiency of an engine was less than it should be. He gave four rules for proper piping, as follows :—(1) The piping and accessories should be so arranged that practically dry steam shall always be delivered to the engine. (2) The steam should reach the engine with very little "drop" in pressure. (3) The piping should be so planned and valves so placed that water cannot, under any circumstances, collect anywhere, except in places especially arranged for that purpose. (4) Wherever practicable, and especially where more than one engine is supplied from one battery of boilers, the piping and valves should be arranged so that, in case of accident to any part, it can be shut off without shutting down the whole plant. The author gave cases illustrating each of the above rules in practice. By attaching a receiver to the pipe close to the engine, he claimed, a large part of the drop in pressure would be avoided, and there would be an improvement in the power developed, and in economy. This last was corroborated by the President, who described how steam was carried over a mountain at one of his collieries, a distance of 4,500ft. by means of a 6in. pipe, and the drop in pressure was but 2lb. or 3lb. He had a large receiver at the end of the pipe, which served as a reservoir for steam and a trap for condensed water. Expansion was provided for by making a right-angle bend in the pipe every 1,000ft., such bend having a large radius.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.

Editorial, Publishing, and Printing Offices:

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.

MUNICIPAL ELECTRIC LIGHTING LOANS.

The loan of £30,000 for electric lighting purposes originally applied for in December, 1892, by the St. Pancras Vestry was approved about a fortnight ago by the London County Council for a period of 25 years, but the Vestry, dissatisfied with the terms upon which it was granted, decided to seek a loan elsewhere, and have accepted the offer of the Prudential Assurance Office, which agreed to the terms originally asked of the London County Council. Much indignation had, moreover, been previously aroused in St. Pancras Vestry circles by a proposal of the Finance Committee of the County Council that the loan should be split up into three portions, to be repaid within periods ranging from five to fifteen years, according as the money was spent on more or less durable work. In a vigorous pamphlet inveighing against this proposal, it was urged that it was contrary to the avowed policy of the Council that it should impose conditions with regard to loans rendering it "impossible for local authorities to undertake electric lighting without casting unjust and unnecessary burdens upon the present generation of ratepayers." No local authority, it was argued, could possibly give to its ratepayers "the benefit of *cheap electricity*, inasmuch as the present consumers would have to be charged a higher rate per unit for electric current than need be the case, in order to extinguish the capital outlay in a comparatively limited number of years"; a consummation which naturally was not to the taste of those who, like the author of the pamphlet in question, start on the assumption that "the municipalisation of the electric lighting undertaking is desirable in the public interest."

There is, however, compensation in all things, and it must be some compensation for those who have had to raise capital for electric lighting purposes under the onerous conditions

Digitized by Google

imposed by the Electric Lighting Acts, to find the biter bit, and to hear the low opinion which municipalities have of short period loans when these are forced upon themselves instead of upon private capitalists. So long as the municipal purchase clause of the Electric Light Amendment Act of 1888 remains on the statute book, so long will it be necessary for any private electric lighting concern, which happens to be prosperous and desires to be provident, to pay a dividend of certainly not less than 5 per cent., to keep its plant in perfect working order, and to set aside annually a sufficient sum towards capital redemption to enable its shareholders to contemplate with equanimity the day of municipalisation. It is true that, according to the Act, a period of 42 years is allowed within which this feat has to be performed, whilst in the case of St. Pancras the maximum period the County Council was originally inclined to permit was only 15 years, and the period finally fixed was only 25 years. But it must not be forgotten that a company is rightly expected to pay a higher interest than 3 or 3½ per cent., and that no monopoly is accorded to it, as is the case with a vestry or other local authority. All things considered, therefore, it would seem as if a private electric lighting concern, with no monopoly, which has to pay 5 or 6 per cent. interest and to redeem the greater part of its capital in 42 years, is in no better position than a vestry with a monopoly which has to pay 3 or 3½ per cent. interest and to redeem its entire capital in five-and-twenty years. Assuming that the St. Pancras Vestry had to repay the whole of the £100,000 it had expended up to December 31st last in 25 years instead of 42, and that the private lighting output remained for five-and-twenty years at its present figure of 400,000 units, the additional sum required to be set aside for the repayment of capital in the shorter period would only mean the addition of about one penny to the total cost of the Board of Trade unit, an addition which increased economy and a larger output would before long obliterate. The suggestion, therefore, that "cheap electricity" is inseparably connected with a minimum of 42 years for repayment of capital will not hold water.

If an inferior runner is given sufficient start he can always win the race. In the same way if municipalities by legislative favours and otherwise are only placed in a sufficiently advantageous position to start with, they will no doubt be able to make a better showing than their hampered rivals, the private capitalists. Is this, then, what we are to understand by municipalisation? Are these its benefits? Because if so, one can have no hesitation in saying they are illusory, and that the community will in the long run repent the error of its ways. If there be any real virtue in municipalising electric light undertakings then it can only arise from the fact that local authorities can really and truly turn out the Board of Trade unit cheaper than can limited liability companies. To first fix the dead weight of the 42 years' purchase clause upon your competitor, trying whenever opportunity offers to make the weight still heavier by cutting down the term of years to 21, and then to deduce the superiority of municipal electric light management from the fact that it can do better than private management so hampered, is to abuse the reasoning faculty. We have no animus against the municipalisation of the electric light, if it can be shown to be "desirable in the public interest." Indeed, it is for this very reason that we hail the decision of the London County Council to insist upon the repayment of all future municipal electric lighting loans in 25 years; this decision, if adhered to, will place private and municipal electric lighting on something like equal footing, and enable non-partisans to judge for themselves whether there be any real superiority in the parochial management of what must ever remain a more or less speculative undertaking, requiring for its successful issue the exercise of just those faculties which have hitherto only been energetically developed by the exigencies of business competition.

But on quite other grounds, there is much to be said in favour of shortening the period for the repayment of municipal electric-lighting loans. The Vice-Chairman of the County Council, in moving that the report of the Finance Committee should be referred back, recommended that the St. Pancras loan should be for the full term sanctioned by the Money Act, 1892, viz., 50 years, or, at any rate, for 42 years, as urged by the Vestry. He admitted that no doubt the present plant, and possibly the present buildings also, would be worn out before then, but plausibly argued that the undertaking of which they formed part would not be worn out, and that there was, therefore, nothing financially unsound in spreading the repayment of the loan over the longer term. The amendment extending the period was, nevertheless, rejected by 61 votes to 36; the argument which closed the discussion being to the effect that if the Council allowed every loan for the longest possible period, they would put themselves in a serious position when they went to Parliament to obtain an extension of the term for housing loans, so that purely selfish, not sound economic considerations had the last word. In the case of long-lived municipal works of public utility and necessity, such as town-buildings, sewers and water-supply, which are not in the least degree likely to become obsolete, and from which the whole community for many generations after will continue to reap benefit, it is both just and proper not to throw the entire burden of repayment upon the generation which is enterprising and public-spirited enough to undertake them; long period loans, are appropriate only in such instances; in all others they encourage municipal extravagance.

The Finance Committee of the County Council, with a truly *doctrinaire* longing for absolute mathematical accuracy, wished to have each individual pound of the St. Pancras loan automatically repaid the very instant the particular object on which it was expended was relegated to the scrap heap. In the same logical spirit it might well be argued that the repayment of loans raised for purposes of public utility and necessity such as those mentioned above should be extended over an indefinitely long period, the sums annually repaid asymptotically approaching zero as the benefit derived from the original expenditure made a similar approach. Practically, however, a limit is set to the indefinite extension of the period for repayment of such municipal loans by the consideration that the life and prosperity of a town is not in the nature of things everlasting, and that a time will, in all probability, come when the repayment of loans contracted in the hey-day of youth will be impossible. But loans for sewers and water-works are one thing, and loans for an electricity supply on the three-wire system another. Traces of sewers and water-works are met with in the excavated remains of every ancient city, but up to the present nothing corresponding to a Kapp dynamo or Brockie-Pell lamp has been unearthed. The difference is no more accidental than is the absence of human remains from eocene deposits. The three-wire system is all very well in its way, but civilised people have managed to live without it before, and may do so again. Candles have superseded torches, and gas candles, whilst at the present time it looks as if electricity were destined to secure whatever lighting is left it by oil; and the march of events is not likely to be arrested by the fact that it will cause considerable inconvenience to a London vestry which has venturesomely em-

Digitized by Google

barked a large sum of the ratepayers' money on an undertaking which must by the very nature of it be more or less of a business speculation, and which would have been on that account far better left in the usual hands, at any rate, for the period allowed by the Act of 1888.

REVIEWS.

Thermodynamics of Reversible Cycles in Gases and Saturated Vapours. By M. I. Pupin, Ph.D. Arranged and edited by Max Osterberg. (New York: John Wiley and Sons. London: Kegan Paul, Tench, Trübner and Co. 1894.)

This little work professes to be a synopsis of a ten weeks' course of lectures delivered by Dr. Pupin, and consists of the revised lecture notes of one of the students. It possesses no table of contents, and is destitute of an index; while the need for these is made the greater on account of the somewhat rambling arrangement of the subject matter. As the Chicago Congress did not venture to crystallise the science of thermodynamics, it may be protested that an author is at liberty to adopt what units and symbols he pleases. But he will select unpopular ones only at the expense of the popularity of his book. A system of thermodynamics based on the metre, the kilogram, and the kgr. calorie is by no means one which can be conveniently compared with the more recognised systems. It is a pity, too, to use the symbol γ for the specific heat of unit volume, since it has been universally adopted by all the authorities as the symbol of the ratio of specific heats at constant pressure and constant volume. Sufficient prominence does not appear to have been given in these lectures to the entropy function, which is granted only a few words of meagre explanation at the end of the sections on perfect gases, and which is only slightly used in the later sections on steam. The prominence into which entropy-temperature cycles have been raised of late, especially in relation to the theory of the steam engine and other heat engines, makes it especially important that the student of thermodynamics should early make himself familiar with this important thermodynamic function and its properties. Absolute temperature is frequently mentioned throughout the lectures; but its true significance, either in relation to the volume of a gas—or more important still—in relation to thermodynamics, is nowhere pointed out. The work is not an elementary one, for it skips many of the essential elements of the science; neither can it be regarded as an advanced one, for it avoids most of the important theorems of advanced thermodynamics. Still, some portions of it are fairly readable; such, for example, as the sections in which the cycles of steam engines are discussed. This work may represent thermodynamics from an American aspect; but English students will do well to select their text-books of the science where they will be sure of getting a clearer and more accurate statement of it, expressed in symbols which everyone recognises and can understand.

The Engineer's Year-Book of Engineering Formulæ, &c. By H. R. Kempe. (London: Crosby Lockwood and Son. 1894.)

This is a mass of useful information very well arranged and printed, and is a development on the lines of Molesworth, Trautwine, and D. K. Clark. The reason for calling it a year-book is not very apparent, but it is stated in the preface that "obviously a work of this nature, to fulfil its purpose of being kept up to date, will require periodical revision, and it is accordingly intended to reissue it from year to year." As in almost all books of this class there is too much condensed text-book matter. The mathematical tables seem to be particularly well done; the linear, superficial and cubical dimensions of segments and zones are given. Square roots and reciprocals running to nine figures, and cube roots to eight figures, for numbers up to 100 are noteworthy. The electrical section contains the everlastingly-repeated diagrams of various windings of field-magnets, together with such rules as "Practically, the armature resistance may be made one-twentieth of the external resistance, and the shunt resistance twenty times as great." "For insulating wires for electric-light purposes india-rubber is preferable to gutta-purcha, as the latter gets soft when heated." This information might have been useful ten years ago, but surely is out of place in a work which aims at being up to date. In a specification for wiring we find a misprint, the only one which we have noticed, platinoid wire of 7·2 millimetres diameter being recommended for fuses of single lamps; 7 mils is probably intended. A few lines farther, on page 470, it is recommended that the centre fillet of wood casing for main cables should be 2in., for branch cables 1in., and for single conductors not less than 2in. The general contents of the book are of a much higher order than is suggested by these extracts, and if such superfluous pages as those devoted to descriptions of square-hole drilling machine, steam hammer, lighthouse construction, and dock gates were omitted, its usefulness would be greatly increased. The book is excellently printed and bound, but is greatly disfigured by a large number of advertisement pages scattered throughout the whole.

Rules for Electricity Works Management. By Albert Gay. (Published by *Lightning*, Limited.)

A set of nine sheets of rules, for engine-drivers, stokers, cleaners, electricians in charge, electricians on mains, wiring inspectors, jointers, meter inspectors, and meter-room attendants have been drawn up by Mr. Gay. These were, no doubt, excellently adapted for the conditions of the House-to-House Company's station at Brompton, where the author was chief engineer, and will doubtless serve for the Islington station which is in his charge. Rules of this sort may be useful as guides or models for other stations, but are not generally applicable, if for no other reason than that an engineer of a station ought to be able to draw up rules for himself, and in nine cases out of ten would very much prefer to do so. We can imagine what a nuisance a fussy vestryman might make, if, armed with these rules, he visited a parochial or municipal station, and inquired into the observance of a few of the regulations taken at random.

THE BRIGHTNESS OF LIGHT: ITS NATURE AND MEASUREMENT.*

BY JAMES MARK BARR AND CHAS. E. S. PHILLIPS.

Of all things in nature for which we feel an appreciation that is definite, light, with its many gradations, would appear to stand first. And at the start it would seem to be a perfectly specific and definite operation to compare one light with a second, and express its brightness in terms of the luminous intensity of the other. But what do these terms define?

The meaning of *brightness* of light, as far as the eye is concerned, does not depend upon one theory or another regarding the nature of light *per se*. But if the emission hypothesis were correct we could have a mental appreciation of brightness which would be quantitative in the material sense, and actual photometry would be analogous to capacity measurement, so that a unit of brightness might be determined apart from the eye, and yet be near in expression to what the eye really gives to the brain as brightness.

Since the emission theory is not correct, we are still further away from the absolute measurement of luminous intensity, and we find it more difficult at the start to grasp the exact meaning of such intensity.

When we define the brightness of light as the luminous intensity per unit area, we are merely stating that the unit of brightness is the brightness of the unit. In such cases as this some arbitrary standard is resorted to for definition. We set up a candle, for instance, and say that there is the unit of brightness, without actually defining the effect at all. Such a standard may meet the requirements for arriving at specific appreciation if we can be certain that it gives constant effects. But it has been said in this journal not long since that "The Parliamentary candle is not a more scientific or accurate standard than was the old barleycorn, of which three went to the inch."

To express luminous intensity we can have no other terms but those for ultimate physiological or, indeed, psychological effect, and we ask: What are these terms? We see at once that it is impossible to measure them directly.

Prof. Langley defines the brightness of light as the intensity of "retinal absorption," and he calls it a provisional definition. But there may be a large gap between the amount of retinal absorption

* Read at the Institution of Electrical Engineers (Students' Meeting), December 15, 1893.

Digitized by Google

and the degree of luminous intensity as felt by the conscious brain.

And aside from this there is a gap between the energy of a light and the amount of retinal absorption which follows. Prof. Langley shows that there is much confusion regarding the connection of "candle-power" with the energy *per se*. *Per se* because, in spite of the law that when there is any physical effect in nature there is always a definite amount of energy at the back of it—in spite of this—the energy here connected directly with the *psychological* effect is quite distinct from the energy related to the production of the light vibrations.

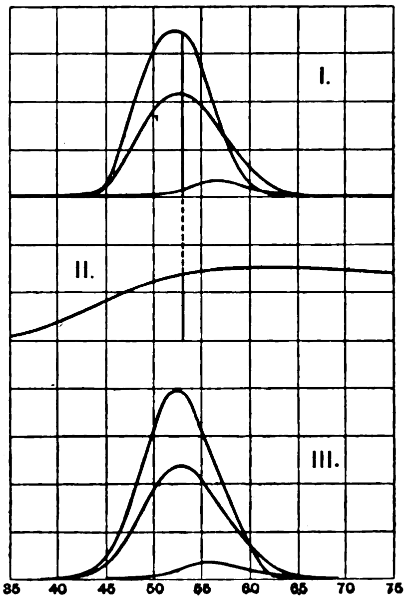

Fig. 1.

The physiological or physical effect at the retina may be proportional to the energy of the spectrum band considered, but because the retina receives, say, a large impingement by radiation, it does not follow that the brain centre will give a message for *brightness* in proportion. The link between primary energy and ultimate psychological effect is quite elastic, though for a monochromatic light the brightness will vary within practical limits directly as the energy or amount of retinal impingement.

If we imagine that there is no such thing as the retina, then light—as light—ceases to exist, and if we were to say generally, that the brightness varies with the energy, then we would say that in the spectrum range of visibility there is more energy than elsewhere. But this, as we have seen, is not true. Professor Langley, in a paper on *Energy and Vision*,* gives the curves which we show in Fig. 1. The curves at I. give the luminous intensity of the

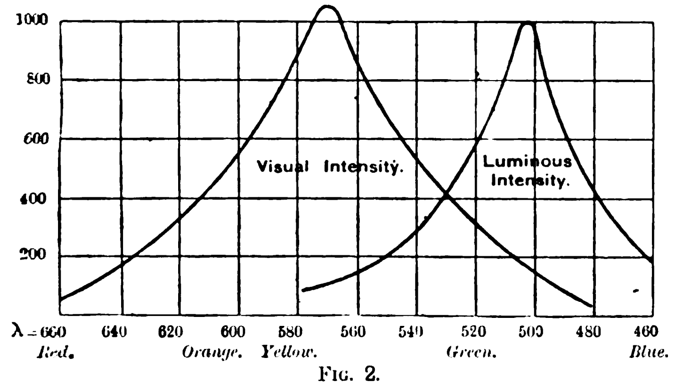

Fig. 2.

normal solar spectrum; curve at II. the thermal energy for above; and curves at III. give the luminous intensity as referred to a constant amount of energy.

The determinations of brightness for the above were made by taking the percentage of correct readings of a table of logarithms illuminated in succession by rays from various parts of the spectrum. This method is regarded by Professor Langley to be the most reliable for photometric work. It is to be noted that there are three curves, one for each of the observers. We see that for different eyes there are different positions in the spectrum for the maximum brightness, and the differences in ordinates show the general variation in strength of eyesight. We call attention to the curves in Fig 2, which are from a Paper by M. Blondel.† This writer takes views diametrically opposite to those of Capt. Abney with regard to colour photometry, and it is not surprising that we here find a use of terms differing from that of Professor Langley. M. Blondel speaks of visual intensity as being distinct from luminous intensity. The curve having its maximum at the yellow-green is labelled "Visual Intensity," and the other "Luminous Intensity." If we reversed the titles then the curves might be accepted as meaning that the eye can *detect* a very feeble green-blue light best, although it would *read* say a table of fine print better with yellow-green rays. This seems rather paradoxical, and we believe that there is something to be said regarding a difference between the words of M. Blondel and Professor Langley.

* Phil. Mag., Vol. 27, p. 91, 1889. † *The Electrician*, December 1, 1893.

But hair-splitting over definitions will not bring us to what is really wanted in the measurement of brightness. We value one light more than another chiefly when we can *find our way* better with one than the other. The practical world requires that the photometer shall tell the candle-power of a lamp in terms of *distinguishing power*. As to the nature of the brightness of light, we can only say that it is first a physical, then a physiological, and lastly a psychological effect. Therefore, its measurement must be relative.

The difference in the position of maximum brightness (*see* Fig. 1) constitutes a great source of error where several are taking the photometer readings. And as there is a great variation in the amount of *power* required to produce minimum visibility with different colours for any one person, it follows that the sources for error when many are reading with "white" light are multiplied. Langley's calculations of the average horse-power required for minimum visibility for three observers show the variation for different colours of the normal solar spectrum to be :—

Violet............................	$\mu 0{\cdot}40 = 18 \times 10^{-15}$ H.P.
Green............................	$0{\cdot}55 = 75 \times 10^{-19}$ H.P.
Scarlet	$0{\cdot}65 = 34 \times 10^{-12}$ H.P.

To sum up, we have the following values of the sensitiveness of the eye for different periods, taking sensitiveness to yellow (sodium flame) as unity :—

Violet	= 0·104
Green	= 5·790
Scarlet	= 0·036
Crimson*	= 0·00007

* At A line.

And compared to green-yellow the rays of maximum brightness, Prof. Langley gives :—

Violet to Green	= 1 to 56
Scarlet to Green	= 1 to 160
Crimson to Green	= 1 to 83,000

Lastly, we must call to mind the variation of the percentages of three colours required to make white light for different people. We see from the above that in dealing with *whitish* lights we are beset with a source of error which cannot be eliminated with satisfaction by practicable means. It is obvious that the use of colour screens will not serve when several are reading, unless the observers use individual glasses which would bring the various points of maximum brightness of spectrum to a common position. But this would not compensate for the above-mentioned error due to differences in power for minimum visibility.

There are a number of methods for determining error due to colour difference, but all of these fail to be of practical use where time is a consideration. We find that the only instrument which would measure the brightness of light regardless of colour is uncalibrated. It is the eye itself. That we do have graduated slide scales in photometry means very little, for what we really want is a quantitative measure of the intensity of brain effect. And how can we do this with the brain itself? We are beset with physiological, or, rather psychological, effects, and as yet there is no psychological unit which we can represent by anything concrete to give to the Board of Trade.

If there were any outside reliable effects in nature which were functions of the actual brightness of light, as we feel it, we would have a photometric principle.

About the only light effect having its maximum in the yellow-green rays is that of the resistance variation of selenium, but of all things to exhibit the total depravity of the inanimate this stands first. The variation of its resistance is truly a function of the brightness, but on a curve which changes totally from day to day.

Fig. 3 shows the inconstancy of two selenium grids made at Pittsburgh, U.S.A., in 1889.

It is usually stated that the maximum reduction of resistance is as 1 is to ½ for dark and light, but it has been found possible to obtain double this variation. The topmost curve in Fig. 3 shows a ratio of 4 to 1 at the beginning, when the selenium had just been annealed.

The grid deteriorates greatly by spasmodic alterations, and it is surprising that we sometimes get indications of a considerable *rise*

Digitized by Google

in the ratio after it has got very low. The effect at any moment is always proportional to brightness in the neighbourhood of the yellow-green rays so that for short intervals it gives a good photometer principal. But it is a question whether or not the variation could be discernible for small differences of candle-power. It is to be noted that there is practically no change for minute alterations in temperature, and that it is not the heat of the spectrum which gives the effects. Light *reduces* the resistance of selenium, and in this selenium acts contrary to the other metals as affected by heat rays. Mr. Mordey suggested to the writers that this might indicate that the effect was due to a change in the *association* of the particles of the granular substance. Mr. Shelford Bidwell, in a Paper before the Physical Society in 1890, has given a most exhaustive account of the nature of selenium changes. He suggests that the whole action is due to the presence of small quantities of a selenide, and that the deliquescence of selenium oxides, always present, give rise to the spasmodic alterations of the ratio. He also points out that the amount of selenide in a grid increases by long use, so that there is a gradual and permanent reduction of the ratio after an excess of selenide is formed. Siemens was one of the earliest to propose a selenium photometer, and a number of arrangements, comprising light sensitive resistance grids and selenium couples in circuit with a galvanometer have been suggested from time to time. But the erratic variation of the ratio gives an insurmountable difficulty, and as yet nothing practicable has been brought out.

We will now refer to other relative measurements. It has been suggested that for a given illuminant we might determine the *heat* produced as an independent variable, of which the brightness of the corresponding light might be regarded as a function, and thus reduce practical, or rather commercial, photometry to thermometric measurement. For instance, if we were making a given kind of glow-lamp

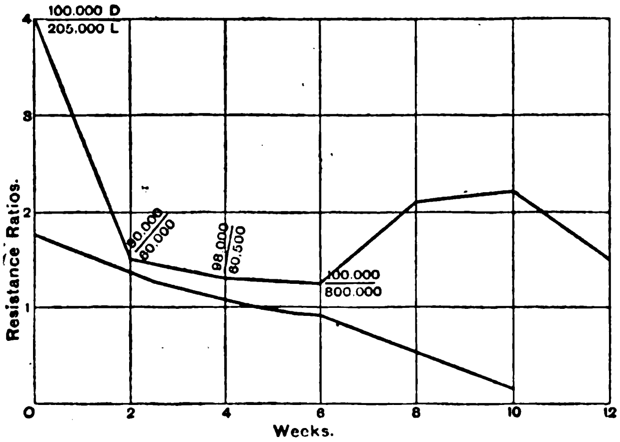

FIG. 3.

filament which had the known curves (Fig. 1) for brightness and thermal intensity, why not measure by a Melloni pile or Bolometer the ordinate Y′ of Curve II., and at once know the ordinate Y of the corresponding Curve I.? It would be just as definite to propose measuring the watts in a given kind of filament as a quantity to which the luminosity is proportional. Speaking generally, the brightness cannot be a perfectly definite function of either the amount of heat or temperature of a number of filaments of one kind, although we can state that in each it varies as some power of the amperes.

If, by attending to an absolutely definite routine of treatment of the carbon, we could make the expression

$$a\left(\frac{A'}{A}\right)^{-a}$$

constant, where A and A′ are two values of current for the candle-powers c and c' in the equation

$$\frac{c'}{c}=\left(\frac{A'}{A}\right)^{a},$$

then glow-lamp photometry would exist on ammeter scales. But the variation in a is beyond every endeavour in the manufacture. Experiments were tried in 1888-9 by M. Lodyguine to control the value of a in the process of making the filaments, but he found that irregularity was inevitable.

On the other hand, it has been proposed to measure the *actinic* effect from a given luminant in order to arrive at the value of the *brightness* of the light. This is slightly more promising from a theoretical standpoint. There are many chemical effects of light, but most of them are too unreliable for practical use. The most familiar actinic actions are those of ordinary photography, and among many others a very ingenious photometric method has been based on the reduction of metallic salts by light.

The next actinic action is that of the formation of hydrochloric acid by light from a mixture of its constituents. A good many years ago Bunsen and Roscoe, and later, Roscoe with Schörlimer, utilised this action of light to measure the solar luminosity during the course of the day and year. They exposed a tank of hydrogen and chlorine to the sun's disc during the whole day, and at intervals removed definite quantities of the gas. A screen was used to prevent too rapid an action.

By noting the amount of HCl formed they obtained values which they took as ordinates proportional to the brightness of the sun at different elevations. From these they plotted curves, which have been made use of in photography. But such a curve really fails to give the *brightness* of the light as we feel it. Gradations of shade in orthrochromatic negatives, exposed with regard to the curve, might give it, however. Other effects of light are as follows:

Sulphur acts like selenium. Chlorine decomposes water upon exposure to light, liberating oxygen. Mercurous oxide decomposes, forming mercuric oxide and free mercury. Nitric acid decomposes slowly. Oxalic acid decomposes slowly. The vegetable green, chlorophyll, liberates oxygen in presence of sunlight. Iodide of nitrogen in ammonia decomposes, liberating nitrogen, the quantity of which is proportional to the intensity of the light. It has not been stated for this action just where the position of maximum effect lies in the spectrum, but for ordinary whitish light it may be taken as practically proportional. We refer later to a photometer which has been based upon this principle. Another chemical effect of light is the production of carbonyl chloride from a mechanical mixture of carbon monoxide and chlorine upon exposure to luminous rays. The combination does not take place with heat, and on account of the light effect this gas has been named Phosgene.

The next effect of light is the most interesting of all, and perhaps is the most promising for use as a measure of luminosity. It is the mechanical expansion of chlorine gas upon exposure to light. The effect is entirely independent of heating, and moreover the gas recovers its original volume upon darkening. This perhaps is the only known direct mechanical effect of those rays which we appreciate as light. The same chlorine can be used over and over again, and for this reason, and also as the action is truly due to luminous rays, Dr. Richardson, of University College, Bristol, thought of utilising it for the practical measurement of the brightness of light. In 1891, before the Physical Society, he pointed out that for rays just a little beyond the yellow-green the method was most accurate.

Few of the above effects could be used for the actual measurement of the brightness of light, but we believe them to be interesting as showing how well surrounded we are with suggestive photometer principles, while we are unable to utilise them.

Since brightness, fundamentally, means some quantity which is referred to a psychological unit, it might seem hopeless to expect by any mechanical means to measure it. However, as is well known, very many methods have been devised to do this, and, although no absolute photometer has yet made its appearance, some of the instruments constructed to measure brightness are of great practical value.

During the latter part of the last century Count Rumford suggested his now well-known method of measuring brightness relatively, by comparing the intensities of two shadows of the same object produced by two separate sources of light. Thus originated the first instrument for measuring brightness, and it is interesting to note that, although many years have elapsed since its introduction, the principle of the modern photometer is essentially that of Rumford. Since Rumford's date much time and labour has been spent in perfecting photometric apparatus, but nothing perfectly absolute has been obtained.

The readings of a galvanometer may be definite, so also the time at any instant can be read from the dial of a clock with accuracy; but with photometers it is different, as sometimes considerable variations occur in the readings taken by different people, all other conditions remaining the same.

This state of things is deplorable, though not astonishing after a little consideration as to the real meaning of the term "Brightness." It is only through the eye* that we realise the sensation of brightness, and since this organ varies in so many ways with different individuals one cannot hope to get a scale of measurement that will be applicable to everyone. Therefore all methods of measuring brightness in which the eye is involved are vague, and so we must look further afield for a principle upon which to base the ideal photometer of the future. If some property of light depending upon its intensity could be utilised—such, for example, as its power to promote certain chemical combinations—then, if in the meantime a definite standard of brightness had been established, photometric measurements would be comparable as regards exactness with those of length and weight. We venture to think that the introduction of such a photometer is not far distant.

* By "eye" here we mean the whole system of nerves which communicate the retinal impressions to the brain, and, indeed, the brain itself.

Digitized by Google

[The authors then proceed to describe a number of photometers, including the Bunsen, Joly, and Lummer-Brodhun.]

The diagrams shown in Fig. 4 were obtained from a large number of photometric experiments carried out at the Central Technical College, and we are greatly indebted to Prof. Ayrton for permitting us to see the original reports upon this work. The diagram is interesting, in so far as it shows the relative efficiency of the most generally used photometers.

It will be at once seen from this diagram that the small star spot photometer is the most efficient of all the instruments tested. The principle upon which this photometer depends is similar to that of the grease spot. Two sheets of stiff white paper with star-shaped apertures (of equal size) cut out from their centres are pasted one on either side of a thin sheet of some semi-transparent paper. The two star-like holes being placed opposite to one another, so that, if

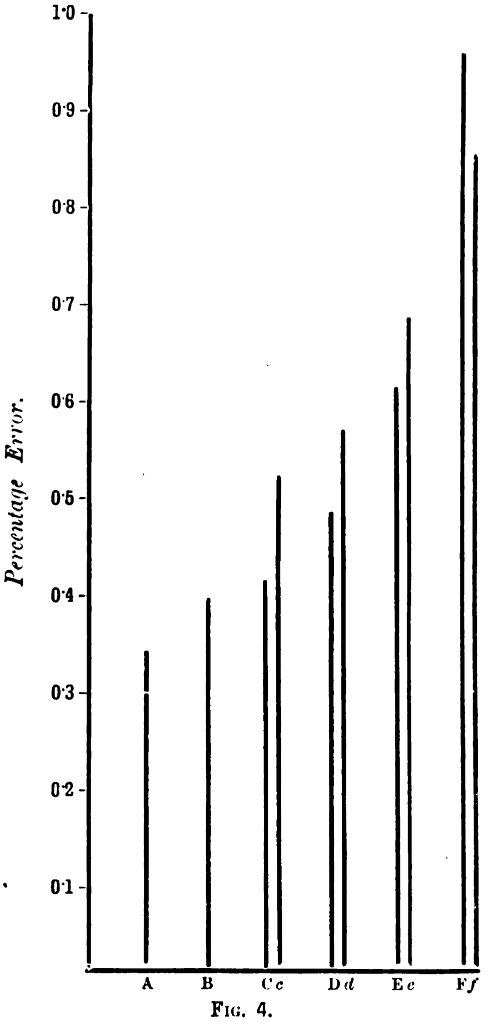

FIG. 4.

F Grease spot, 400 cms.
f do. 192·5 cms.

the arrangement be held up to the light, the star will be clearly seen. The method of using this photometer is exactly similar to that for the grease spot already described. In using paper screens, as in this case, it is particularly necessary to keep them scrupulously clean. At the Westinghouse photometric department considerable use is made of this photometer.

[The authors then quote descriptions of chemical and other photometers from the *English Mechanic*, April 22, 1881; *Nature*, December 8, 1881; *ibid*, Vol. XLII. p. 511. They allude to the MM. Legul and Verscheffel's modification of the radiometer, to the work of Mr. A. Wurts, Mr. A. P. Trotter, Mr. W. H. Preece, Prof. Pickering, and Prof. Thorpe, the two last relating to stellar and solar photometry.]

We have already referred to chemical photometers, and mentioned some of the more theoretical methods. The following two ways of measuring brightness we venture to suggest ourselves.

It has been shown by several investigators that some of the chemical-light effects may be used in photometry with practical approximation to accuracy. However, aside from Roscoe's work upon the solar intensity (using mixture of 2 H and Cl, as described), Dr. Richardson's experiments with chlorine, and the investigations of Bidwell and others upon selenium variation, little has been done to bring out a practical photometer based upon these effects.

It is generally supposed that it is only the *actinic intensity* of the light which is involved, and that therefore it is a vain effort to attempt to measure *illumination intensity* by the chemical-light effects.

But there are several gases which show a maximum of action in the yellow-green rays, and this, considered with the fact that in the largest practical use the kind of illuminant would not vary within wide limits, should give us some hope for a new photometer.

No investigations have conclusively shown that the action of carbonyl chloride may not be utilised for the practical measurement of candle-power. The writers venture to suggest a simple photometric arrangement involving the use of the above gas, and it is probable that with an approximately constant kind of illuminant, the instrument could be used practically. Carbonyl chloride is formed from a mixture of carbon monoxide and chlorine upon exposure to white light, and the mixture changes in volume from one to half when all combination is completed. For the measurement of high candle-powers it is proposed to employ a cylinder of the above mixtures exposed to the lamp and connected to a simple manometer tube, arranged to indicate in a magnified way a change in pressure in the cylinder. Arrangements would be made for compensating for the heat effects and for the regulation of the gas pressure.

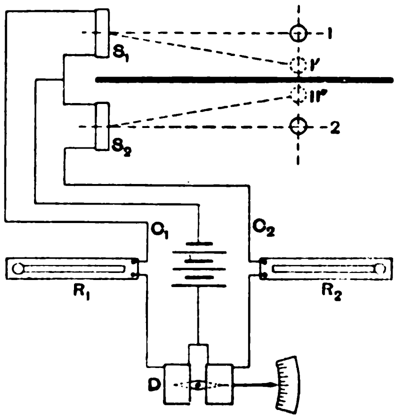

FIG. 5.

The second method we suggest consists in an attempt to use selenium grids in such a way as to give accurate results independently of any of the variations to which they are so liable. All that is required of the selenium grids in this case is that a change in the resistance takes place, which is greater the brighter is the light, without constancy or proportionality. Two selenium grids are arranged in differential circuit with a galvanometer, and both are exposed to the standard in succession. By means of adjustable resistances the deflections to right and left are made equal, so that now, if both grids are exposed simultaneously to the same light, there will be no deflection, see Fig. 5. After c_1 and c_2 are adjusted as described, the standard is placed at the position 1, and the lamp to be measured placed at position 2. Now, any deflection of the galvanometer will have no quantitative value, but will indicate simply that a *difference* exists between the two lights, and it shows by its sign which way the unknown must be moved on its scale to bring the illumination at s_2 and s_1 to equality. This only requires that the grids remain constant in action for a moment at a time. For electric standards it would be convenient to have two standards at 1′ and 1″, so that during measurement they could be flashed on and off at intervals as a check on the action of grids.

We had hoped at the outset to have given a more complete account of light-measuring apparatus, and to have described in some detail the ingenious photometric methods of Capt. Abney and Mr. Trotter.

Time will, unfortunately, not permit this, and we must also for the same reason abandon the consideration of light standards, a subject of so much importance and so closely related to photometry.

We feel, however, that we cannot conclude our remarks without thanking those who have so kindly helped us by supplying suggestions for this Paper. More especially are we indebted to Prof. Ayrton for his valuable advice upon some of the more intricate parts of our subject, and for permitting us to read the original reports on some of the extensive photometric investigations that have been carried out at the Central Technical College.

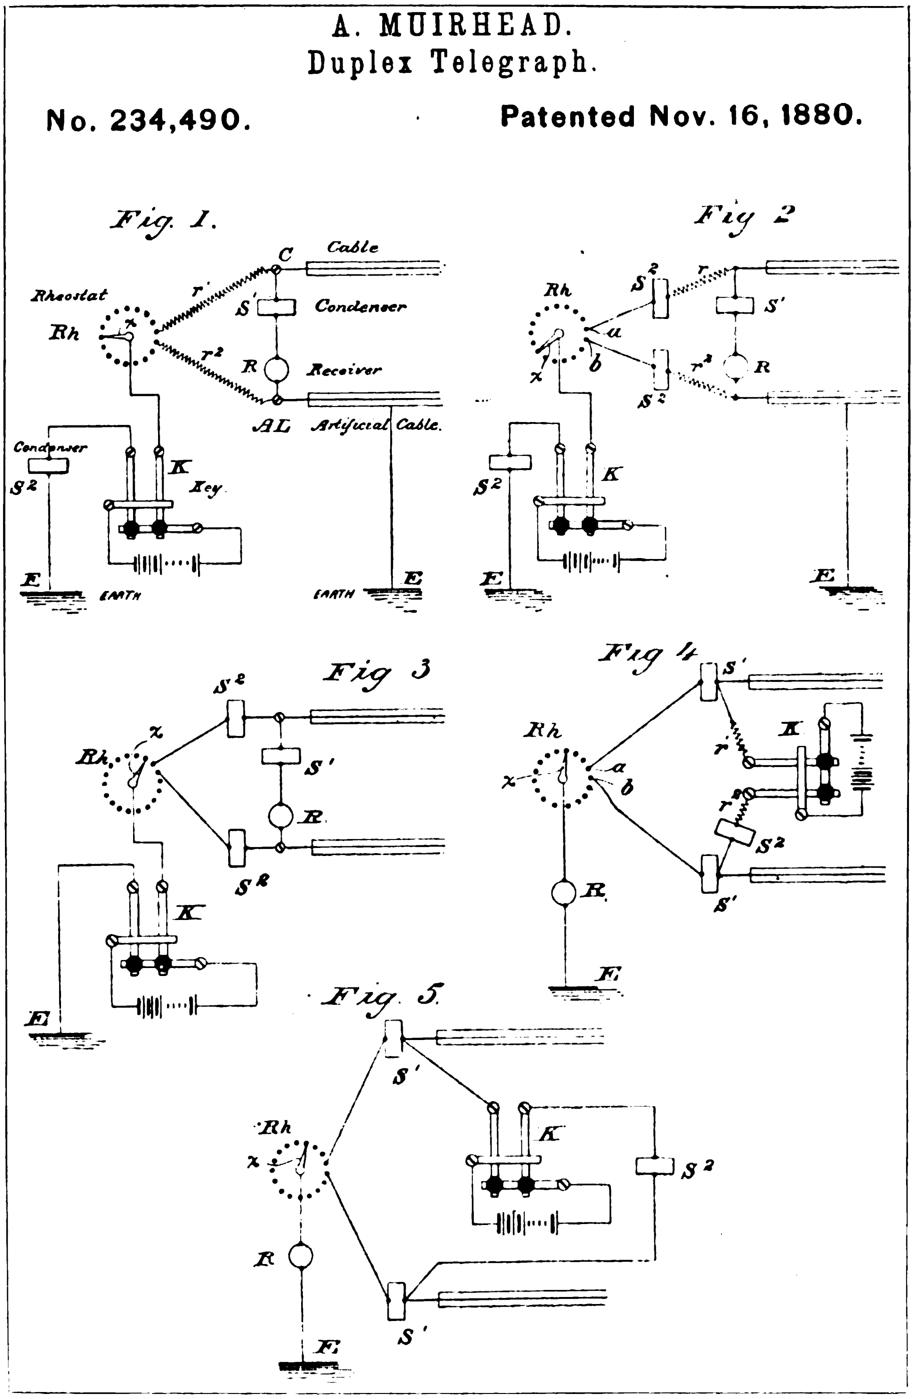
LEGAL INTELLIGENCE.

Muirhead v. The Commercial Cable Company.

This case came on for hearing before Mr. Justice Kennedy in Queen's Bench Court III., on Wednesday last week. Mr. Finlay, Q.C., Mr. Bousfield, Q.C., M.P., and Mr. E. H. Pollard appeared for the plaintiffs, instructed by Messrs. Trinder and Capron. Sir Richard Webster, Q.C., M.P., Mr. J. F. Moulton, Q.C., and Mr. A. J. Walter appeared for the defendants, instructed by Messrs. Budd, Johnsons and Jecks.

Mr. FINLAY said that the action was brought to recover royalties under an agreement giving the defendants a right to use certain patents belonging to the plaintiffs. The sums claimed in the action were £1,879. 18s. 9d. for royalties due from July to September, 1891, and £1,685. 2s. 8d. for royalties from September to December, 1891, making together £3,566, but the decision of the action would involve the decision practically as to whether the plaintiffs were or were not entitled to recover royalties from July, 1891, up till November, 1897, that being a sum of about £45.000. The question in dispute was whether one of the patents (United States 234,490 of 1880) comprised in the plaintiff's licence to the defendants was or was not still in force. The defendants sought to attack the patent on the grounds of American law, though precluded from averring that a patent under which they took a licence was invalid—they sought to show that it was invalid *pro tanto*, and ceased to exist at the same date at which a so-called identical British patent No. 2,564, of 1876 came to an end. A licensee, like a lessee, though he could not dispute his landlord's title, might show that it had expired, but if the mode in which the defendants sought to show that the plaintiffs' patent had expired involved an attack on the patent itself, it would not be open to the defendants. The plaintiff was the patentee of a very ingenious system of duplex telegraphy. On January 2, 1884, he granted a licence to the Commercial Cable Company. Counsel then proceeded to recite in some detail the terms of the licence, Article 9 of which provided that the contract should be construed as an English one, and to describe the principles underlying duplex telegraphy as applied to submarine telegraphy. The importance of the United States patent No. 234,490, of 1880, was, Counsel stated, due to the fact that, by the combination of a rheostat with the three condensers, one on each arm of the bridge and one on the line on which the receiver was situated, it enabled them to get together two things which previously had been incompatible. These were the greatest possible speeds of transmission with a perfect balance. For the purpose of facilitating the obtaining of a balance before this invention, telegraphists were constrained to employ very high resistances, going up as far as 2,000 ohms on each arm of the bridge.



Reproduction of the Drawings from the American Specification of 1880.

THURSDAY, MARCH 1ST.

On the hearing of this case being resumed, Prof. SILVANUS P. THOMPSON, examined by Mr. Bousfield, stated that he had had his attention particularly called to three patents, the United States patent, No.

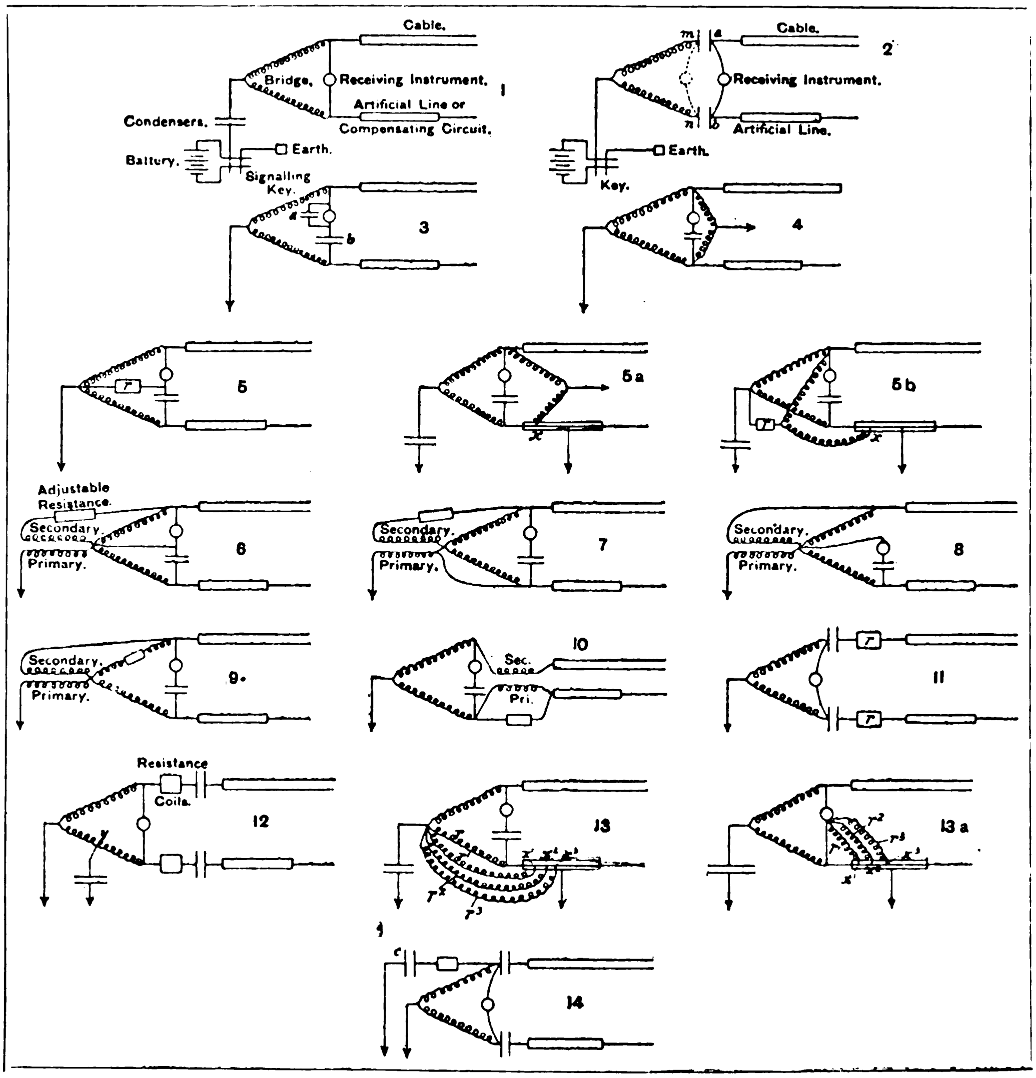
Digitized by Google

234,490, of 1880, and two English patents, 2,564, of 1876, and 2,538, of 1877. Witness then explained to the Court the general principles of duplex telegraphy. Examined on the American patent 234,490, of 1880, witness explained that the changes which were introduced in the arrangements shown in that specification in Figs. 2 and 3 was that in Fig. 2 the resistances r^1 and r^2 of the bridge arm had been reduced, because there had been interposed in each of the two arms a condenser. That was the only difference between Fig. 2 and Fig. 1. In Fig. 3 the resistances r^1 and r^2 of the bridge arms had been entirely removed, and instead there are simply the condensers S^2—one in each arm. That was the point of novelty—that hitherto large resistances had been employed in the bridge arms—resistances of a magnitude comparable to the cable itself. In Fig. 3 the rheostat discharged precisely the same function as it did in Fig. 2, namely, that of enabling a small adjustment to be made. The first claim of the American patent was for the combination in a telegraphic circuit of "the battery, the key, the adjustable rheostat, the sending condensers each in a bridge wire, the cable or true line connected with one section of the condenser and the artificial line with the other, and the receiving instrument and its condenser." In the former patents referred to of 1876 and 1877 he did not find this combination. There was no rheostat used with

Mr. BOUSFIELD: I submit that to take one point after another and attempt, as it were, to break down the 1880 patent on the ground that this, that and the other was known, is not within the scope of these gentlemen, who are licensees, and therefore cannot attack the validity of this patent in any shape or form. They can only succeed, as my learned friend Mr. Finlay submitted, and I take it there cannot be any controversy about that, by showing that the invention which is covered by the 1880 patent is to be found patented in either 1876 or 1877.

Sir RICHARD WEBSTER: I desire your lordship to understand that the sole point and object I am cross-examining to is to show that to any electrician the two things are identical, and so far from disputing the validity of the 1880 patent or the 1876 patent, I am simply directing myself solely to the issue. which is the only issue in this case, whether or not there is any substantial difference between the patents of 1880 and 1876.

Sir RICHARD WEBSTER (continuing cross-examination): In so far as the receiving instrument is on the cable side of the condensers, does it (Fig. 2, English patent) not exactly correspond with the change that is made in the American specification between Fig. 1 and Fig. 2 of the American specification?—In so far it does correspond.



Drawings from the English Duplex Telegraph Patent, No. 2,564, of 1876.

a bridge arm resistance in the 1876 patent. As regards Figs. 4 and 5, they referred to another point of novelty. "The combination in a telegraphic circuit of the receiving instrument the adjustable rheostat the separate condensers in the bridge wire one connecting with the true and the other with the artificial line with the key battery and condenser in the bridge or circuit between the two cables."

Cross-examined by Sir Richard Webster WITNESS said a rheostat was nothing more than a *readily* adjustable resistance. Wheatstone's receiver was a particular form of it; they merely had to turn a handle until they obtained the resistance required. He did not think a resistance box could be called a rheostat. The condenser, S^2, near the key in Fig. 1 (U.S. Patent), had nothing to do with the balance bridge there. Condensers were used in that way long before the duplex was introduced. It was quite immaterial whether the resistance was put one side or the other of the condenser. It was essential in duplexing that as nearly as possible a perfect balance should be maintained in the two arms of the bridge.

Sir RICHARD WEBSTER: Now, in Muirhead's English specification, Professor Thompson, the two bridges which are there shown as r^1 and r^2 are shown there as a sort of little twisted wires?—Yes.

Must there not have been in order to keep the proper relation between the cable and the artificial cable a means of adjusting the resistance in those two bridges?—No, not if you had the one on the artificial cable.

Look at Fig. 2 and Fig. 3 of the American specification. Will you compare that for a moment with Fig. 1. Is not the change from this point of view—leaving out adjustable resistances at present—is not the change from Fig. 1 to Fig. 2, or to Fig. 3, that the condenser is taken into two pieces—is split—one part is put on the part of the bridge going to the main cable, the other is put on the part of the bridge going to the artificial cable?—Yes, in so far.

And the position of the receiving instrument with respect to those condensers is identical with the position of the receiving instrument shown in thick lines on the right hand side of Fig. 2 of the English cable?—It is in Fig. 3, not in Fig. 2.

Look at Fig. 2?—In Fig. 2 the condenser is nearer the rheostat, and the resistances are beyond.

I am speaking of the position of the receiving instrument. If you will look at the position of the receiving instrument in Fig. 2 of the English patent on the right hand side—the thick line—it is on the cable side of the condenser?—It is.

That is its position in both Fig. 2 and Fig. 3 of the American patent?—Yes, so far.

Re-examined by Mr. Bousfield: WITNESS said that as regards the combination of rheostat and bridge wires shown in the 1880 patent, he knew of no better combination that could be used. The particular arrangement

Digitized by Google

of the rheostat at the apex of the bridge gave the best result he knew of, for the reason that it afforded such a very ready and reliable way of making the small change that was required. In the 1876 patent the only indications relating to adjustments are those that relate to adjustments effected not on the bridge arms or at their point of junction, but on the artificial cable. The arrangement of getting a balance indicated (Fig. 4 of the 1876 patent) was not, in his opinion, as good as the one in the 1880 patent of the United States, because the use of that method diminished the sensitiveness of the receiving instrument; it shunted some of the current off. The arrangements in figures 5*a* and 5*b* (English patent) were entirely different to the arrangement in the 1880 United States patent. The electro-magnetic devices referred to in the English patent were less desirable than the arrangements referred to in the United States patent. No one of the arrangements for obtaining a perfect balance at the two arms of the bridge was the same as the arrangement described in the United States specification of 1880, though the nearest was Fig. 4 (English patent) because it had all the elements of the rheostat.

Mr. FINLAY: My lord, I am now in a position to make a statement about the Canadian patent, so that your lordship and my friend may not be taken by surprise. I do not propose to dispute that the Canadian patents are identical in fact with the patents of 1876 and 1877.

Lord KELVIN was then examined by Mr. Bousfield, and stated that there was no general knowledge of instruments used for duplexing submarine cables in 1876. He believed duplexing was done entirely by Messrs. Muirhead and Mr. Taylor. In his view the use of the rheostat and its use in the particular point indicated in the United States patent was a matter of great importance. It was of great importance to keep r plus r^1 constant. In Fig. 3, for example, of the American patent the only resistance in the bridge was the resistance in the rheostat. Even assuming that r and r in Fig. 11 of the 1876 patent were rheostats, he did not find any indication in the 1876 patent which would lead a person to place a rheostat at the junction of the arms of the bridge, so as to get the results which come from the 1880 patent. Supposing the simple 1880 method of balancing had been known in 1876, he could not conceive of anybody going out of his way to construct a method of balance such as that shown, say in Fig. 13 (patent of 1876).

Cross-examined by Mr. Moulton, WITNESS said that neither in the 1876 or 1877 patent was there any indication of any means accessible to the operator for performing adjustments. It was of importance to keep the sum of the two resistances constant.

Re-examined by Mr. Bousfield, WITNESS said that the shunting effect would be increased when r plus r^1 was diminished, and would be diminished when r plus r^1 was increased; when r plus r^1 was increased the signals would be stronger, when r plus r^1 was diminished the signals would be weaker.

Mr. JUSTICE KENNEDY: Would you mind turning to Fig. 1 of the 1876 specification? Does that show to you as a scientific electrician any method of adjustment?—It shows no method of adjustment.

The other figures, more or less, do show, do they, methods of adjustment, or not?—The diagrams do not actually show, but the letterpress describes.

Sir RICHARD WEBSTER: Taking the figures as they stand with any explanation of those figures that appears in the specification, a rheostat, such as appears in the 1880 patent, would not be workable?—It would not be workable, certainly.

Mr. JUSTICE KENNEDY: Do Fig. 1 and Fig. 2, with any explanation of those two figures that you find in the text, lead you to a conclusion one way or other as to whether a rheostat would be workable with those at the point of the apex?—No; decidedly not. There is no direction given to place one there. If we are to hold, as I have heard in Court it is held, that each of these resistances is to be adjustable, they must be separately adjustable; I mean to say it is not stated that they are adjustable at all in the specification. Of course, we all know that the electrician would have to adjust, but he would adjust each one, and he would not apply an instrument which would automatically throw in resistance to the one and throw out to the other.

It is plain that what you call the working of a rheostat so as to preserve the sum does not, in your opinion, fit in with Fig. 1 or Fig. 2?—No; certainly not.

Sir FREDERICK BRAMWELL, examined by Mr. Finlay, stated that he quite agreed that in 1876 the rheostat was a well-known instrument, but he did not agree that it was an obvious thing to employ it for the purpose for which it was employed in the 1880 patent; basing that answer upon the fact that in 1876 Mr. Muirhead apparently did not know how to do it.

Cross-examined by Sir Richard Webster, WITNESS stated that according to his reading of the 1876 patent all the descriptions were self-contained; that was, 4 to 14, and that everyone of them would produce the balance without the addition of any adjusting instruments. He had not sufficient information of detail to know whether the position he suggested was the right or the wrong one.

Sir RICHARD WEBSTER: Am I not correct that from beginning to end of the 1876 specification you find no indication of the kind of adjusting instrument that is to be used anywhere. If an adjusting instrument is necessary in view of what is shown in the specification, you find no kind of indication what adjusting instrument is to be used?—No. If there be anything beyond what the patentee has pointed out in detail. I find no direction as to its nature or as to how it is to be used.

I am also correct, am I not, that if you look in the 1880 specification beyond the word rheostat and the picture there is nothing to indicate the particular class of resistance adjusting instrument to be used?—Not beyond those words.

I should like to ask you this, will you undertake to say that a rheostat would not be a most useful instrument in several of those figures there shown, 4 to 14, assuming that further arrangements are required?—I think it would be.

Friday, March 2nd.

On the hearing of the case being resumed Mr. GEORGE MOCKRIDGE was sworn, and examined by Mr. E. H. Pollard. Witness stated that he had been superintendent of the Western Union Telegraph Company at Penzance since 1881. He had previously been a cable operator in the Direct United States Company. The Direct United States cable was duplexed in 1878. It was duplexed on the ordinary bridge system, with resistance coils as the arms of the bridge The Penzance cable was duplexed in 1883. When this was duplexed they also used the rheostat at the apex of the bridge. The double-block or condenser system was used first on that cable in March, 1887. The resistance coils were removed altogether, and only the rheostat and the condensers in the two arms were used. The result was a 30 per cent. increase in speed.

Mr. HERBERT TAYLOR, examined by Mr. Bousfield, stated that in 1875 Messrs. Muirhead and he began to plan the scheme which they now had in use. In 1876 they actually applied it in successful working. The state of common knowledge in the years 1875, 1876, 1877, 1878, up to then, as regards duplexing of submarine cables was nil, except speculative knowledge, theoretical knowledge. In practice there was none till they did it. The successful duplexing of a long submarine cable was first done in March, 1876, on the cable between Marseilles and Malta, 800 miles. The crux of duplex working at that time was to make the artificial line of sufficient electrical resemblance to the cable, so that the receiving signals did not send the receiving instrument wild—and so that the sending signals did not upset the receiving instrument. The first submarine cable duplexing upon the double block system without any resistance in the arms of the bridge was done in 1884.

Cross-examined by Sir Richard Webster, WITNESS stated that the effect of the arrangement depicted in the specification of 1876, Fig. 2, was that the arms of the bridge could be greatly reduced in resistance with a consequent reduction in the retardation of the signals.

Sir RICHARD WEBSTER: Was not that in consequence of putting the condensers into the bridge arms?—Yes.

And was not that exactly the same operation as is described in the American patent, namely, of reducing the resistance of the bridges. Answer that question please?—I cannot say yes or no.

Answer that question, and then add any explanation you like!—It meant greatly reduced—not abolished.

I did not say anything about either greatly reduced or abolished. Was not the putting of the condensers into the bridge arms the invention whereby you were able to reduce the resistance. I care not whether it is reduced or abolished?—Yes, that is the claim.

Was not that the invention in 1876?—Yes, it is claimed.

Now no means of adjustment are shown in Fig. 2?—No.

I put it to you, with your knowledge, having been working at this as you have from 1875, would it not have been impossible to work Fig. 2 without some means of adjustment?—Adjustment where?

Of resistance in the bridges?—Yes. I would not say impossible, but nobody would have dreamed of doing it.

Will you look at the description of the invention from line 17 to line 37, and see if there is the slightest reference there to any method of adjusting the resistance. I think you can take it from me that there is not, but by all means look?—I think not.

Mr. Justice KENNEDY: What was there in 1880 that you did not know in 1876?—We were unable in 1876 to overcome the difficulties in obtaining a balance—we could not without large resistance in the bridge—which greatly facilitates the maintaining of the balance, we could not get a balance.

Prof. JAMES THOMSON BOTTOMLEY, examined by Mr. Finlay, stated that he had carefully examined the patent of 1880 and the English patents of 1876 and 1877. Two main advantages were secured by the 1880 patent. One was the obtaining a balance and preventing the sending instrument at the given end from interfering with the receiving instrument at the same end. The other advantage was the obtaining of distinct legible signals. He had never heard of that combination having been made before 1880. In his judgment, turning to the patent of 1876, he did not find any anticipation in that patent of the combination in the 1880 patent. A resistance box would not keep the sum of the resistance in the two arms constant. It would change the one arm without changing the other also. It was essential where quick sending was concerned to keep the sum of the resistance the same while altering the ratio, because if the small resistance employed in the 1880 patent were adopted, any little alteration on the total amount of the bridge would upset the signals of the receiving instrument. In 1876 and 1877 the first thing that had to be done in duplexing a cable was to guard the receiving instrument so that it should not be driven completely wild by the sending signals at its own end. For this purpose they had to introduce the most elaborate guards, which cut down the speed of the signalling instrument to say 60 per cent. They succeeded in doing that, and it was a great feat to do it. The combination of balance with speed could not be secured except by the combination shown in the 1880 patent.

Cross-examined by Sir Richard Webster, WITNESS stated that in a duplex system without condensers the use of a rheostat would not enable one to adopt low resistance instead of high. The sole function of a rheostat was to adjust the balance in a duplex system. Essentially a rheostat was something that would not break the current. There were resistance boxes made which could be used so as not to break the current. Fig. 2 of 1876 could not possibly be worked without an arrangement for adjusting the resistance in the bridges. In Fig. 2, 1876, he did not find any direction in the specification as to how that adjustment of the bridge arms should be done. He had stated that it was most important that r plus r^1 must be constant, and was ready to pledge his reputation from practical knowledge that r plus r^1 must be kept practically constan tin order to make the thing work properly, though it might be increased (diminished a little.

Digitized by Google

Dr. ALEXANDER MUIRHEAD (examined by Mr. Finlay) said that he was the grantee of the American patent of 1880, and had never used that combination before.

Cross-examined by Mr. Moulton, WITNESS stated that the difference between Fig. 1 and Fig. 2 of 1880 was putting the condensers into the bridge arms. Putting the condensers into the bridge arms enabled them to use much lower resistances in the bridge arms.

Mr. JOHN MUIRHEAD, examined by Mr. Finlay, said the patent of 1876 was granted to him, and the patent of 1877 was granted to him jointly with Dr. Alexander Muirhead.

Dr. JOHN HOPKINSON, examined by Mr. Bousfield, gave a *résumé* of the differences between land-line duplexing and the duplexing of a submarine cable. As far as he knew, in the year 1880 it was a new thing to use a rheostat in combination with condensers and without any other resistances. There was nothing in the 1876 patent which would lead one to the combination shown in the 1880 patent.

Sir RICHARD WEBSTER then proceeded to summarise the American law on the subject of the duration of patents granted in the United States for inventions previously patented abroad, and argued that the 1876 patent was included in the 1880; although 1880 might include further improvements, it did not affect the question. If the plaintiff's statement was true—if the invention of 1880 was a new and different invention from that of 1876, it was not protected by letters patent in this country at all. The case that he had to suggest was that in 1880 it had been found out that the particular combination shown by Figs. 2 and 3, 1876, was practically speaking the best, if not the only useful combination of those described. The pith and marrow of the 1876 invention was the insertion of the two condensers at a particular place in the bridges.

SATURDAY, MARCH 3RD.

On the hearing of the case being resumed, Sir RICHARD WEBSTER continued his argument. The answers of all the witnesses, he said, clearly showed that the invention, which everybody had recognised as being the invention until the necessities of the case suggested another view, was putting the condensers in the bridge instead of putting them in the combined sending wire. In Fig. 1, of 1880, the inventor described what he did not want to patent. He described in Fig. 2 what he did want to patent, and the only change was the putting in the condensers. He submitted that it was quite clear that in 1880 the patentee picking out what was best in his invention of 1876, telling it to America, desiring to have the best patent he could, there picked out the best part of the 1876 patent, and he picked out the condensers in the bridge. There was not a witness who had suggested that the use of the rheostat *per se* made any difference at all in the great advantages which were claimed by both patents, and in obtaining the objects which were specified on the face of each patent. What was the position with regard to Fig. 2 of the 1876 patent? Common knowledge that the best way of adjusting the resistance of the bridges was by putting a rheostat at the apex; no direction in the specification of the patentee as to what kind of adjustment resistance to use; admission by witness after witness called that in order to work the invention, the great invention specifically described—in order to obtain the objects specifically described—one must have some method of adjusting the resistance in the two bridge arms: statement of the patentee. "This patent is to be read excluding the most common way of doing it." He (Sir Richard Webster) was going to call witnesses—who had done as much work in duplexing of cables, and had as much experience as any other persons whose names could be mentioned. They would state that the introduction of the rheostat was the most common means—as Sir Frederick Bramwell admitted—of adjusting the resistance, in the manner employed in the patent of 1876. Something of the kind must have been implied, otherwise the invention could not be worked at all. It was treated as common knowledge by Mr. Muirhead in that year, and he was not entitled, in order to make out that there was a different invention in the 1876 to that in the 1880 patent, to come now and say that so far from being common knowledge it was to be treated as the pith and marrow of the invention of 1880; there not being one single word in that specification of 1880 to give the faintest indication that the rheostat was of any importance, having regard to the position in which it was placed.

Prof. ANDREW JAMIESON, examined by Mr. Moulton, stated that he was assistant to Sir William Thomson and Prof. Fleeming Jenkin in connection with the making of the Western Brazilian and the Platino-Brazilian cables. At the end of 1873 he was sent out to Brazil. In the autumn of 1876 Sir John Pender and Sir James Anderson secured his services, and authorised him to make himself fully acquainted with duplex telegraphy in every sense, and proceed as soon as possible to Marseilles and to Malta in order to readjust the duplex system as put up there by Dr. Alexander Muirhead, Mr. Munro, Mr. Laughton, and others. In duplexing it made no difference whether they used an apparatus like a resistance box or a rheostat. It was of no practical effect whether they made the adjustment by the rheostat at the apex or the rheostat in one arm, or the rheostat in the other arm. In 1876 a competent electrician looking at Fig. 1 would understand by the lines to the left that they were formed of adjustable variable resistances. With regard to Fig. 2, he would suppose that the lines were exactly the same, namely, adjustable variable resistances, which would be absolutely necessary in order to make the thing work. A competent electrician at that date would not require any specific statement that they were to be adjustable variable resistances. In his opinion, as a competent electrician, there was nothing more told in Fig. 1 of 1880 than was told in Fig. 1 of 1876. All that was told by Fig. 1 of 1880 over and above Fig. 1 in 1876 was the receiving condenser and the rheostat as depicted at the end of the line. As a matter of substance, that latter was no information to a competent electrician beyond what the 1876 patent told. Looking at the 1880 specification, and comparing Fig. 2 and Fig. 1, in his opinion, the invention shown in Fig. 2 was the introduction of condensers in each arm of the bridge, which he found also in the 1876 specification.

And to a competent electrician, do you find that the specification of 1880 tells of any other invention excepting that?—It does not. It was of no importance to keep the sum of the resistances in the two bridge arms constant, and, as a matter of fact, it was never done.

Cross-examined by Mr. Finlay, WITNESS stated that at Malta, on the Malta-Alexandria No. 2 cable, along with Mr. Benjamin Smith, he adopted, about 1876, the duplex arrangement with all resistance entirely eliminated from the arms of the bridge. He had a condenser in each arm of the bridge, a condenser on the receiving circuit, but no rheostat at the junction. The arrangement adopted there for adjusting the balance was adjusting the condensers on one side or the other. The process adopted at Malta was described in Mr. Benjamin Smith's patent of January 5, 1876, No. 47. It was a fact that in that description and drawing there was no condenser on the receiving circuit; that was a mere appendage of the receiver like the battery. The use of resistance boxes in the cable, as described in the Smith patent, for the purpose of obtaining a balance, had the undesirable effect of reducing speed. He was of opinion that with that apparatus the results could be obtained which were stated by the Messrs. Muirhead to have been obtained—95 per cent. of improvement over the simplex method—on a long cable.

Mr. FINLAY: How on earth did this valuable invention disappear after a day or two?—After we got the thing into perfect working order, when I reported to Sir James Anderson on the thing, he said, "Jamieson, I believe thoroughly in Muirhead's duplex; be good enough to remain with that."

He thought Muirhead's was better?—He did.

He thought it was better?—Yes, in every sense.

And so yours disappeared?—It disappeared for the time being.

The Court then adjourned until Monday.

A summary of the proceedings of Monday, Tuesday and Wednesday, on which day the Court sat until 10 p.m., will appear in our next issue. At the conclusion of the hearing of the case, judgment was reserved.

Edison-Bell Phonograph Corporation (Limited) v. Smith and Young.

This motion came before Mr. Justice Wright on Tuesday last to commit the defendant Young to Holloway prison for contempt of Court, in parting with the possession of certain phonographs made in infringement of plaintiffs' letters patent by shipping such phonographs to one Van Obett in Amsterdam, on February 5th, in breach of an undertaking given by defendants' counsel to the Court on February 3rd. It was also complained that Young continued to offer phonographs for sale in breach of an injunction granted on February 3rd, as reported in *The Electrician* on February 16th.

After hearing counsel, His LORDSHIP said that from the materials before him he should not be justified in committing the defendant. The defendant denied that he had parted with any instruments, and as to the offering for sale, he was not satisfied that defendant was a principal. As to the costs, however, he could not give the defendant costs, there being so much suspicion in the matter.

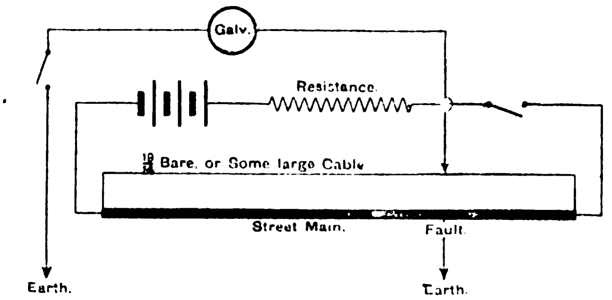
Motion dismissed, without costs.

CORRESPONDENCE.

LOCALISING FAULTS IN STREET MAINS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following method has occurred to me as suitable for locating earth faults in short lengths of large section street mains for electric supply.



But not having yet tried the same I write in the hope that any reader, who has so applied the Wheatstone bridge, will be good enough to communicate his experience through your columns.

The bare $\frac{19}{14}$ cable is to be attached as above to defective cable, and laid above surface of ground along line of cable below. This bare cable is to be well insulated from earth.

Of course, on obtaining balance, the sliding contact should be over the fault.—Yours, &c., W. H. COLLIS,

Inspector of Mains to the Liverpool Electric Supply Company (Limited).

VARLEY TESTIMONIAL FUND.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: We beg to inform your readers that the accounts of the Varley Testimonial Fund must be closed on the 15th of the current month. We therefore make a last appeal to all those who have in one form or another benefited by the invention of the dynamo, compound winding, and other matters with which Mr. Varley's name has been so largely associated, to send in a subscription to the undersigned before the above-mentioned date.—Yours, &c.,

A. Stroh, Honorary Treasurer.
R. E. Crompton, Honorary Secretary.

March 2, 1894.

DOUBLE-ACTING GAS ENGINES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In the letter you kindly inserted in your issue of February 16th last, I referred to the six-stroke cycle Griffin engine as obsolete. It was well-known that the sole licensees of this engine had abandoned it, but I now learn that Messrs. Griffin and Co., of Bath, have arranged to take up its manufacture. This being so, it is not right to say that the engine is "obsolete," and in justice to Messrs. Griffin and Co., I shall be glad if you will allow this correction to appear.—Yours, &c.,

March 3, 1894. J. Emerson Dowson.

THE EWING MAGNETIC MODEL.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I am surprised to see in Mr. Evershed's article on p. 481 of the current number of *The Electrician* that I am credited with having devised a model for illustrating Prof. Ewing's theory of magnetisation. In justice to Prof. Ewing I wish to state that I had no hand whatever in the matter. The model was described by Prof. Ewing in the same Paper as the theory (*Proc.* Roy. Soc., 1890) and was exhibited by him at the British Association meeting in the same year. Twelve months later I determined the magnetisation curve for a group of magnets, which Prof. Ewing has reproduced in his book on magnetism, but even for this I can claim no credit, as it was merely given to me as a problem in Practical Physics by the examiner for the Cambridge Science Tripos —Yours, &c.,

J. W. Capstick.

Trinity College, Cambridge, March 6, 1894.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Through your courtesy I am enabled at once to notice Mr. Capstick's letter. I need hardly say that in writing as I did I had no intention of ascribing the credit of discovering the model to anyone but Prof. Ewing himself. Your readers cannot be so ungrateful as to have forgotten that the first model was described and exhibited by Prof. Ewing at the B. A. meeting in Leeds in 1890, since which time it has always been known as the "Ewing model."

In writing of a "Ewing-Capstick" model I was under the impression, derived from the footnote on page 329 of Prof. Ewing's "Magnetic Induction," that Mr. Capstick, in answer to an examination question, designed and made a model with the special intention of obtaining a cyclic curve. In this I was clearly mistaken, but I am bound to say that some credit for experimental skill is due to Mr. Capstick for the very perfect cyclic curve he was able to secure with a model containing only twenty-four magnets.—Yours, &c., Sydney Evershed.

Woodfield Works, March 8, 1894.

Steel Castings for Dynamos.—Writing in the *Journal* of the Franklin Institute, Mr. H. F. Parshall states that steel castings are largely used for dynamo-building in the States. The permeability of this material is about 20 per cent. greater than that of cast iron, but from 20 to 25 per cent. less than that of wrought iron. The 1,500-kilowatt generator, built for the Brooklyn-street Railway Company by the General Electric Company, has wrought-iron cores, and a steel casting weighing 38,000lb. as the yoke-piece.

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

Our readers are reminded that the 1894 Edition of "The Electrician" Electrical Trades' Directory and Handbook is now ready. This valuable book contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

"Electrical Engineering Formulæ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.) A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). prospectus on application to the Publisher.

"Electromagnetic Theory," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"Drum Armatures and Commutators."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.) Prospectus on application.

Tenders Invited.—The Stafford Corporation invite tenders for the erection of buildings for their new central electric supply station. Specifications, &c., can be obtained of Mr. J. F. Bell, engineer, the Gas Works, Stafford; and tenders must be in to Mr. M. F. Blakiston, town clerk, before noon of the 19th inst.

——— The Manchester, Sheffield and Lincolnshire Railway Company announce that they are prepared to receive tenders for the supply, for the year ending April 30th, of various stores, including telegraph materials and wire. Tenders must be in by March 20th.

Tenders Accepted.—The Lancaster Town Council have accepted the tender of the Brush Company for extending their mains along St. Leonard-gate for the sum of £147.

Appointments.—Ninety-eight applications were received by the Electric Lighting Committee of the Edinburgh Corporation for the post of city electrical engineer, and from this number three candidates were selected by the Committee for submission to the Town Council for their final choice. These three were Messrs. E. W. Monkhouse, of the Westminster Electric Supply Corporation, London, and Messrs. R. A. Chattock and G. B. Dunn, of the Metropolitan Electric Supply Company, London. The Town Council have decided in favour of the first-named gentleman; who is appointed at a salary of £180.

——— For the post of electrician-in-charge of the central station at Londonderry the Electric Lighting Committee received seventy-one applications, and at the request of the Corporation Messrs. Siemens Brothers and Co. selected three of the number for the Council to choose from. There were Messrs. John Christie, of the Glasgow Corporation Electric Lighting Stations, H. C. Kromschreider, of Woolwich; and Albert Barnes, of South Kensington, London. Mr. Christie was on Tuesday appointed to the position by the Corporation.

——— Mr. H. M. Sayers, now superintending engineer of the Companhia de Luz Elettrica, Oporto, has been appointed Superintending Engineer of the Bournemouth and District Electric Supply Company.

Liquidations.—Notice is given that the following persons have been appointed a committee of inspection to act with the Official Receiver and Provisional liquidator:—Messrs. John Hampton (holding a general power of attorney for I. and S. Roberts, Limited), Henry Percy Dodson (holding a general power of attorney from Reuter's Telegram Company, Limited), Charles Henry Cox, Thomas Bell Elliner, Edward Bond, William Stevens Squire, William Duncan, Thomas Pilling, and Sir James Clarke Lawrence.

——— Mr. Justice Vaughan Williams, on Wednesday, ordered the voluntary winding-up of Latimer Clark, Muirhead and Co. (Limited) to be continued, under the supervision of the Court.

——— Creditors of the Platinum Plating Company (Limited) (in voluntary liquidation) must send in their claims to the liquidator, Captain R. W. Shackel, Elmhurst, Mitcham Common, by the 31st inst.

——— The first meetings of creditors and of contributories of Newington, Priddle and Co. (Limited) will be held at 33, Carey-street, W.C., on the 15th inst., at 11 and 12 respectively. Under the winding-up order made last January against this Company. accounts were issued on Wednesday showing debts £1,210. 19s. 10d., ranking against assets £744. 1s. 4d., and a total deficiency of £6,446. 18s. 6d. to contributories. The sole right to

Digitized by Google

manufacture and sell the "Phonautograph" was acquired by the Company in May, 1893, and a sum of £500 was advanced to the inventor to be repaid out of the profits on the sales, but no such sales have been effected. To the lock up of that £500 and to insufficient working capital the failure of the Company is attributed.

Electric Lighting Plant for Disposal.—The London and India Docks Joint Committee are prepared to receive tenders for the purchase (including removal) of a large quantity of second-hand electric lighting plant. Tenders must be in not later than March 31st, addressed to the Chairman of the Works and Stores Committee. Further particulars are given in our advertisement columns, and all other information can be obtained at the Dock House, 109, Leadenhall-street, London, E.C.

Messrs. Crompton and Co. (Limited).—We have received a copy of a handsome complete catalogue just issued by Messrs. Crompton and Co., containing nearly 200 pages of closely-printed matter concerning their special manufactures of electric plant, machinery, and apparatus. In issuing this catalogue, Messrs. Crompton and Co. point to the fact that their large works at Chelmsford originated in the visit of Mr. Crompton to the Exhibition at Paris in 1878, where he made the acquaintance of M. Gramme, and brought back with him to England a pair of Gramme dynamo machines. This was the commencement of the works at Chelmsford, where and on their various contracts nearly 1,000 hands are now employed. The firm are manufacturing and exporting to all parts of the world every requisite necessary for electric lighting, power transmission, electro-metallurgy, and electro-chemistry, for which they have gained the highest awards at all the great exhibitions held since 1878. It is pointed out that since the issue of their first catalogue in 1889 great reductions have been made in the prices of their manufactures, which have now reached an abnormally low level. The catalogue is divided into eight sections, all of which are very fully illustrated. For convenience many of the figures in the tables are printed in two colours. In addition to well-executed drawings of the well-known Crompton dynamos, motors, and combination sets, some excellent illustrations appear of electric travelling cranes, drills, and motors, electrically-driven fans and blowers, hoists, cranes capstans, and pumps. In the electric traction section the Southend Electric Tramway, for which Messrs. Crompton and Co. are the engineers and contractors, is shown, and the electric haulage plant at the Abercanaid Colliery is also pictured in a subsequent section. Arc lamps and lanterns are fully dealt with, and the section devoted to measuring instruments is a very full one. A large number of flattering testimonials, covering a long period, from users of Messrs. Crompton and Co.'s plant, accompany the catalogue, and the list of contracts carried out and customers supplied occupies many pages, including no less than 22 complete central stations, both at home and abroad, in addition to 10 others for which plant and apparatus have been supplied or are on order. The letterpress particulars accompanying the various sections make the catalogue most complete and useful.

Messrs. Mather and Platt.—The London office of this firm have recently completed an electrical installation at Emmanuel College, Cambridge, the plant of which consists of a 20-b.h.p. portable engine driving an Edison-Hopkinson dynamo. About 300 incandescents are used.

Messrs. Perry and Co.—The Empress Frederick paid a visit to the show rooms of this firm in Grafton-street, Bond-street, London, W., last week, to inspect the various methods devised by the firm for effectively lighting picture galleries and works of art by the electric light. Her Imperial Majesty gave several orders, and expressed her appreciation of the successful efforts made by the firm in their various designs for lighting art galleries to the best advantage.

Messrs. Rashleigh Phipps and Co.—Amongst the contracts in hand by this firm may be mentioned an additional 1,000 lights for Messrs. Marshall and Snellgrove, for their extensive premises in Oxford-street and their new premises in Vere street, London, W., the plant including four sets of accumulators. Three hundred lights have just been completed at the mansion of the Hon. H. Sturt, M.P., in Portman-square.

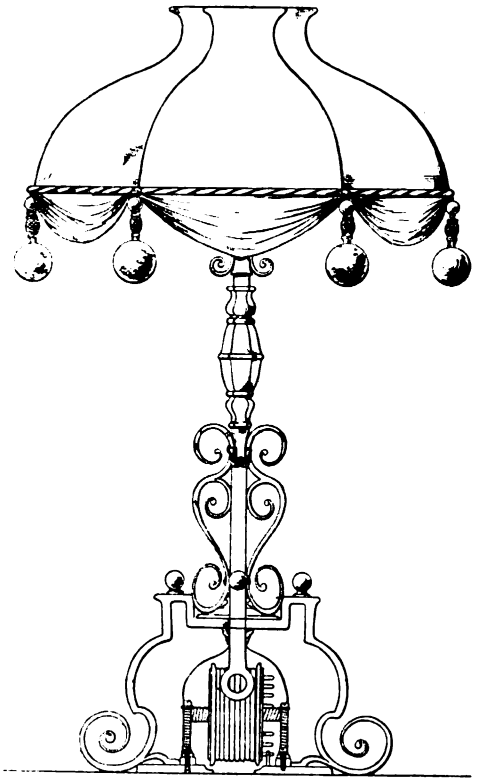
Telephonic Communication.—It is announced that the first step has been taken towards the establishment of telephonic communication between Copenhagen and Berlin, the Finance Committee of the Copenhagen Parliament having reported in favour of the proposal received from the German Telegraph Department that the cable between Copenhagen and Odense shall be so laid as to form part of the eventual telephone line to be carried through Odense, Kolding, and Hamburg to Berlin.

"Science Progress."—This is the title of a new monthly review of current scientific investigation, which is published by the Scientific Press (Limited), of London. Price 2s. 6d.

Antwerp Exhibition.—Mr. G. R. de Courcy-Perry, Her Majesty's Consul-General at Antwerp, and British Commissioner-General for the Exhibition, notifies that France, Germany, and other European States are making strenuous efforts to be well represented at Antwerp. Every facility is being given to British manufacturers to enable them to exhibit, but time is very short. It has, therefore, been arranged that Prof. W. Layton shall attend daily at the offices of the London Chamber of Commerce, Botolph House, Eastcheap, E.C., between eleven and four o'clock, on and after the 12th inst., to give all necessary information, and to treat with intending exhibitors for the allotment of space.

Launch.—The Thames Electric and Steam Launch Company have recently completed and launched the steam yacht "Britannia," of 65 tons register and 40 tons displacement, which is the largest vessel of the kind ever built and launched above the new lock at Richmond, now nearly completed. The "Britannia" is to carry an electric pinnace, the accumulators for which are charged from a specially designed charging plant on board, and is also provided with an electric lighting installation to be supplied from the same accumulators or plant. The Company also announce that they will shortly launch a new vessel, designed for passenger traffic on the Thames, having a 70ft. promenade deck, and lighted by arc and incandescent lamps.

Automatic Winding Gear.—The illustration below shows Hedge's patent automatic winding gear for portable lamps, by which the action of the helical spring, which is contained in the porcelain reel, is controlled by a small stud projecting from the base of the lamp, so that when placed on the table the spring is inert, but comes into action directly the lamp is raised. It is claimed for this invention that it can be applied to either large or small lamp pedestals. The illustration shows a design made by



Starkie Gardiner, where the winding gear is contained between the legs, and is, therefore, not unsightly. It is especially useful where it is desirable to keep electric lamps out of a room until they are actually required to be used, such as in hotels and restaurants. The drums are arranged to mark either horizontally or vertically. The device is manufactured by the Carboid Oil-less Gearing Company under licence.

"Inverted" Arc Lighting.—Messrs. Dobson and Barton (Limited), of Bolton, have placed a contract with Messrs. Lowcock, Hill and Co., of Manchester, for the lighting up of a portion of their Bolton machine shop with 120 inverted arc lamps, and also with a large extension of their incandescent installation.

Aberdeen.—While general satisfaction is expressed at the public lighting by electricity, a proposal is to be made askin the Town Council to provide additional lamps, as those already erected are, in the opinion of many, too far apart.

Belfast.—The Electric Lighting Committee of the Corporation have reported that it will be necessary for them to appoint a resident engineer for the electric lighting station, to superintend

Digitized by Google

the erection of the plant and the laying of the mains, under the direction of their consulting engineer, at a salary of £250 per annum. This proposal has been approved. The committee further report that they hope to have the electric lighting works completed, and to be able to supply consumers within the compulsory area, by September 1st next.

Brighton.—The Town Council have had before them the electric lighting accounts for the past year, in which it is stated that £4,011 is the net revenue received, enabling the Council, after paying off large amounts of capital and interest, to carry forward a credit balance of £300. The number of houses connected with the electric current has increased from 215 in 1892 to 423 in December, 1893, and 1894 shows even more satisfactory progress. The question of lighting the Council Chamber by electricity is to come before the next meeting of the General Purposes Committee.

Bury.—At a Town Council meeting last week the Borough Engineer presented his report upon the system to be adopted for the electric lighting scheme. The Electric Lighting Committee had visited the stations at Liverpool, Bradford, and Leeds, and had selected the continuous-current system with accumulators. It is proposed to put down plant equal to a supply of 4,000 8-c.p. lamps, but the central station is to be built for an ultimate capacity of 7,000 lamps. 150 Epstein cells are to be included in the plant. The Committee are considering the question of the utilisation of waste heat from the destructor.

Burnley.—The Board of Guardians are undecided whether their intention to spend money upon the installation of the electric light in the Union offices is unusual and extraordinary, and therefore cannot be legally sanctioned, or whether it is quite legal, and in accordance with precedent. The Clerk maintains that the latter is the correct view.

Cheltenham.—At their last meeting the Town Council discussed the report of the Electric Lighting Committee, which recommended that the tender of Messrs. Siemens Bros. and Co., of Westminster and Woolwich, be finally accepted for the sum of £4,610 (including Willans engines). The subject has been before the Council many times during the past seven years, but notwithstanding this, a motion that the matter be again deferred "for the purpose of affording the Council an opportunity of obtaining further information," was adopted, on the understanding that in the event of the sanction of the Local Government Board being forthcoming the Mayor will call a special meeting of the Council for the acceptance of tenders.

Derby.—At the last Town Council meeting it was proposed that an electrical exhibition should be held at Derby, and that the Electric Lighting Committee should be authorised to expend a sum not exceeding £200 on the project. In support of the proposal, Mr. Marsden stated that the Committee had spent £30,000 on electric lighting, and that instruction had been given in public on gas-cooking, and it was only fair that electricity should have a similar opportunity. The resolution was carried.

Derry.—A Local Government Board inquiry has been held in reference to the application by the Corporation for sanction for a supplemental loan of £5,000 to complete the electric lighting works, making in all a total of £78,000 expended on these works. In explaining the necessity for this further loan, Mr. M'Cay, the city solicitor, stated that as time went on it was found that additions were necessary to the plant, and other departures had to be made from the original specifications, but in every case the Corporation were justified in the extra expenditure incurred, notwithstanding the unreasonable opposition which the Corporation had met with in carrying out their scheme. The money had all been expended for the public good, and when the work was completed the result would be a good and sufficient answer to the opponents of the scheme. Councillor Magee, the Chairman of the Lighting Committee, said the Committee had been throughout influenced in some items of expenditure by a desire to make a thoroughly good job of the electric lighting; all the apparatus used was of the best description, which was advisable where a permanent installation was intended. Mr. Blake, the Corporation's electrical engineer, also gave evidence bearing out the statement of the City Solicitor and Chairman of the Lighting Committee. The opponents to the Corporation's scheme (who were represented by Mr. O'Doherty) contended that the original estimates were glaringly inaccurate, a contention which was strongly opposed by those responsible. It was fitting that the local gas company should oppose the application and Mr. B. H. Lane, who represented their interests, stated that in the estimates prepared by the Lighting Committee no notice had been taken of a very large claim which the Gas Light Company intended to lodge, but which the Corporation intend to vigorously dispute.

Edinburgh.—The Electric Lighting Committee of the Town Council have decided that the charge per unit for electric current shall be 6d. for lighting, and 3½d. for motive power.

Fleetwood.—The Lighting Committee of the Improvement Commissioners will shortly visit the Coatbridge electric lighting station in order to inspect the working of the gas engines in parallel, which is a similar system to that proposed to be adopted at Fleetwood.

Hampstead.—The Vestry are applying to the London County Council for a further advance of £5,000 for electric lighting purposes.

Lancaster.—The Town Council propose to borrow a further £5,000 for the purposes of the electric lighting scheme.

Littlehampton.—The Local Board have received a communication from Mr. W. E. Hayne, of Brighton, in reference to the dissatisfaction expressed at the gas supplied at Littlehampton, and suggesting a scheme for the electric lighting of the district. Mr. Hayne points out that, although Littlehampton is a comparatively small town, it is daily increasing in size, and is, moreover, a port and health resort on the South Coast. He adds that there is a suitable ground near the waterworks for central station, and intimates that certain manufacturing electrical firms are prepared to supply the requisite machinery and cables, for which, if a local company is formed, they would be willing to take part payment in shares to the extent of at least £1,000, *i.e.*, presuming the Local Board were unwilling themselves to undertake the control of the electric lighting supply. The letter has been referred to a special lighting committee for consideration.

Liverpool.—Mr. Councillor Houlding has for some time past advocated the adoption by the Liverpool Corporation of a steam refuse destructor, and the City Engineer (Mr. H. P. Bulnois) has, in conjunction with the Health Committee, erected on Corporation land in Chisenhall-street destructors for this purpose. Connected with the destructor apparatus is a 60-h.p. engine, from which it is proposed to derive motive power for an electric motor to light the whole of the yards in connection with the Chisenhall Department of the Corporation. The engineer's report has been presented, and states that to replace the gas jets at present in use, the engineer proposes that six 2,000-c.p. arcs and 20 sets of incandescent lamp fittings shall be used, and that the only additional plant necessary would require an expenditure of about £260. The proposals in the engineer's report have been approved by the Committee.

———— A letter has been addressed to the Lord Mayor of Liverpool by the secretary of the Liverpool and Vicinity United Trades and Labour Council, enclosing a copy of the following resolution recently passed by that body:—"This meeting urges upon the City Council, in view of the present exorbitant price of gas, to consider the possibility of utilising the tidal force for the generation of electricity, thus improving the lighting of the city at a reduced cost to the ratepayers."

London County Council.—The Highways Committee have again recommended that the Victoria Embankment should be lighted electrically from standards erected in the centre of the thoroughfare.

Maidstone.—The Local Board are still in doubt as to the advisability of proceeding with the electric lighting business. They have postponed giving their final decision in the matter till Wednesday next.

Mill Lighting.—The extensive mills of the Ulverston Paper Works, near Barrow, are now lighted throughout by electricity, the contract having been carried out by Messrs. W. R. Thornton and Son, of Barrow. About 500 8-c.p. lamps are provided for.

Monmouth.—The Town Council have received a report from Messrs. Bramwell and Harris on the combined scheme for electric light and drainage in the borough, and in particular on the practicability of utilising the water of the River Wye as motive power. This report fully approves of the scheme as set out in the plans prepared by Mr. Lailey, but does not approve of the site selected for the turbines. The site recommended is on a now disused watercourse at the Old Forge, on the River Monnow, where a continuous supply of water, with a fall of 9ft., can be relied upon all the year round. This arrangement would allow of the sewage pumping machinery being fixed on a convenient place and worked by electric motors. The report was ordered to be printed and considered.

Morley.—The Town Council have received a report from the Electric Lighting Committee stating that various schemes have been considered for the lighting of the district, and visits have been paid to Bradford, Huddersfield, and Leeds. The premium offered by the Council for the best scheme of electric lighting has been awarded to Mr. Robert Hammond. It is estimated that the initial scheme will cost £15,000, and is to be similar in principle to that established at Leeds by the House-to-House Company. The Committee are preparing a detailed report, and will shortly ask the Local Government Board's sanction for a loan.

Rothesay.—The new Glenburn Hydropathic Establishment, which has been erected on the site of the old building destroyed

Digitized by Google

by fire in 1891, has been partly fitted for the electric light by Messrs. Claud Hamilton (Limited), of Glasgow, the dining-room being fitted with twelve 3-light electroliers, and the drawing, billiard, reading and writing, and recreation rooms with brackets and electroliers. The recreation room has a handsome 10-light electrolier designed by Mr. Crawford, the architect of the building, and the stage, which forms a part of the recreation room, is completely lighted by electricity. Messrs. Ransomes, Sims, and Jefferies have supplied the motive power, which consists of two high-speed vertical double-acting engines of 60 i.h.p. The cables, wiers, &c., are of Silvertown make.

RUGBY.—The Chairman of the Local Board announced at the last meeting that the public gas lighting contracts are now falling in and their renewal would be shortly necessary. In reply to a question as to a chance of having the electric light, the Chairman said that there was no possibility of any such improvement.

SCARBOROUGH.—At the Mayor of Scarborough's "At Home," held at the Grand Hotel, last week, the Scarborough Electric Supply Company (Limited) gave an exhibition of electrical appliances, which included lighting, heating, and cooking by electricity. A fine exhibit was made by the Edison & Swan Company who contributed samples of the various products of their extensive works at Ponders End and South Benwell, as applied to domestic and public lighting advertising and general utility, consisting of Electroliers, Brackets, Pendants, Electric Motors, Measuring Instruments, Clocks, and other accessories. Several hundred varieties and types of Incandescence Lamps of various shades and colours were shewn including their new Sunlight High Candle Power 2 watt lamps. One of the great attractions of the evening was an illuminated device containing about 150 series lamps composing the words "Success to Scarburg," the old Saxon name of the town. A large party were entertained, and took great interest in the exhibition, which was of a very comprehensive character, and included everything from an 8-c.p. incandescent lamp to the penny-in-the-slot machine now in use on the Metropolitan District Railway. Mr. A. A. Campbell Swinton, the Managing Director of the Scarborough Company, gave a series of experiments with the electric current, and effectively explained, with the aid of Mr. Peck, the apparatus on view. The large banqueting hall in which the exhibition was held was crowded, and much interest was taken by those present in the variety of uses to which electric current can now be applied. On Wednesday Mr. J. Hutton explained to the members of the Constitution Club the uses of the electrical apparatus on view at the club, which formed part of the exhibit at the Grand Hotel and which had been lent for the occasion.

SHIRLEY AND FREEMANTLE.—The Local Board are discussing a proposal to light the district by electricity. The matter is under the consideration of the General Purposes Committee.

ST. OLAVE'S (SOUTHWARK).—Mr. G. W. Thompson, surveyor to the Board of Works, has presented a report to that body on the electric lighting question. He recommends that the larger thoroughfares be lighted by arc lamps, and the minor streets by incandescents ; 32 of the former would be required, and 386 of the latter. In the event of any difficulty being experienced in obtaining a satisfactory site for the central station, Mr. Thompson suggests that permission be obtained to moor a barge on the Thames to contain the necessary plant. Mr. Thompson estimates the cost of lighting the district, exclusive of building site and cost of Provisional Order, at £21,269, and the annual charges at £2,429. These estimates are based upon a supply of 1,000 lights for private lighting in addition to the public lighting. The report is decidedly favourable to the early introduction of the electric light.

ST. PANCRAS (LONDON).—In consequence of the demand for current in the principal thoroughfares off the Tottenham Court-road district, the Vestry have decided that mains be laid in Goodge-street at an estimated cost of £560. The offer of the Prudential Assurance Company to loan the Vestry £15,400 at 3½ per cent. for 42 years, for electric lighting purposes, on the security of the rates, was agreed to. It will be remembered that the London County Council refused to grant the loan for a longer period than 25 years.

WALTHAMSTOW.—The Local Board have appointed a sub-committee to inquire and report as to the practicability of adopting the electric light.

WIRE STEALING.—The two men, Borette and Denny, accused of stealing 210 yards of copper wire, the property of the Postmaster-General, were brought up at the London Central Criminal Court, on Tuesday. Denny, upon whom the property was found, was discharged, and Borette was sentenced to fifteen months' hard labour. It appears that the wires had been cut between Liverpool-street and Stratford on many occasions, with the result that the Fire Brigade had been turned out to false alarms.

WOOLWICH.—The Local Board have decided to defer the consideration of the proposal to light the Town Hall and municipal offices by electricity for three months.

WOTTON-UNDER-EDGE.—The inspectors of this district, appointed under the Lighting Act, will shortly advertise for tenders for lighting the district by oil, electricity, or gas.

STAFF DINNER.—The annual staff dinner of the National Telephone Company was held on Friday evening last at the Holborn Restaurant, Holborn, W.C., under the presidency of Mr. E. L. Gaine, the general manager. About 200 sat down to dinner, including Sir A. K. Rollit, M.P., Mr. Albert Anns, secretary, Mr. Dane Sinclair, engineer-in-chief, Mr. Calder, Mr. Phillips, Mr. Fletcher and other prominent officials of the Company. The toast of the evening was "The National Telephone Company and the Board of Directors," in proposing which the Chairman expressed his regret at the absence of the President and Vice-President. He said the enterprise in which the National Telephone Company was engaged had been beset with many difficulties of a most worrying nature. Those present might rest assured that the steady progress which the telephone had made in a city like London was not secured without a tremendous amount of detail work, and this also applied to all large centres. Perhaps, however, the unkindest cut of all had been the declaration of legal opinion that the telephone was a telegraph. The National Company owned upwards of 100,000 miles of wires, and at the present time these wires carried 250 million messages per annum, and they had upwards of 540 exchanges throughout the country. With regard to the question of the telephone being a monopoly, he contended that in the very nature of things the telephone was a monopoly, and must remain a monopoly, whether owned by the State or in the hands of a private company. Mr. Dane Sinclair replied to the toast of "The Science and Progress of Telephony." Amongst other toasts that of "The Post Office" was proposed by Sir Albert Rollit and responded to by Mr. Ardron, of the Post Office ; and that of "the Chairman" was proposed by Mr. Joseph Chambers, superintendent of the Company's Northern Province. The musical programme was a strong one, the Blue Hungarian Band adding much to the evening's enjoyment, and professional friends of the staff providing excellent vocal music. The dinner was altogether a great success.

SMOKING CONCERT.—The London staff of Messrs. Drake and Gorham held a smoking concert on Friday last, at which a large party of *employés* and friends were present.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

January 27, 1894.

1,776. W. A. WALTON. Improvements in electric arc lamps.

1,788. J. P. BAYLY. London. Improvements in electric glow lamps. (W. Wiklund, Sweden.)

1,794. W. ADKINS. Birmingham. Improvements in electrical traction or electrical railways and tramways.

1,798. J. W. FLETCHER. Stockport. Improvements in electrical signalling apparatus, and in apparatus connected therewith.

1,810. H. E. S. HOLT. Teddington. Improvements in electrical measuring instruments.

January 29, 1894.

1,886. H. MARRIAN. London. Improvements in switches and automatic movements for use in connection with telephones.

1,903. M. WUILLOT. London. Improvements in or relating to electrodes.

1,919. C. LANGDON-DAVIES. London. Improvements in telegraph relays.

January 30, 1894.

2,007. THE EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED) and C. F. PROCTOR. London. An electric switch.*

2,048. R. VOIGTLÄNDER. London. Improvements in dynamometers.

January 31, 1894.

2,093. H. H. BROWN. London. Improvements in the manufacture of insulated wire.

2,104. G. J. GUHL. Croydon. Improvements in electric switches to be used in conjunction with contacts for continuous ringing.

2,105. F. BROWN and C. H. OFFORD. Walsall. Improvements in arc lamps.

2,112. T. H. CALEY. Manchester. Improvements in electric lampholder switches, and the like.

2,118. V. FABRIS. London. Electric light improvements.

2,203. G. DURLACHER, A. LACOSTE, and W. LOWRY. London. An improvement in electric candle lamps.*

2,211. Sir C. S. FORBES, Bart., and the DOMESTIC TELEPHONE COMPANY (LIMITED). London. Improvements in microphones.

2,217. H. CHITTY. London. Improvements in dynamo-electric machines.

2,250. O. HUND. London. Improvements in galvanic batteries. (G. Wehr, Germany.)

2,251. O. HUND. London. Improvements in galvanic dry batteries. (G. Wehr, Germany).

February 2, 1894.

2,262. A. ASHBY. London. Improvements relating to electroliers, and ceiling roses for same.

2,271. C. R. G. SMYTHE and A. H. DUNNACHIE. Glasgow. An improved method of constructing manholes, inspection boxes, junction boxes, and the like.

2,274. P. J. PRINGLE. Sidcup. Improvements in the means for electrically propelling tramcars and other vehicles, and the apparatus therefor.

2,321. W. E. YATES and A. CLEGG. London. Improvements in or connected with dynamos.

February 3, 1894.

2,366. J. E. PALMER. Birmingham. System of underground electric traction.

2,424. D. DE MITO. London. An electric locking device for door locks.

2,437. A. A. CARDOSO E BASTOS. London. Improvements in and relating to electric time alarm and synchronising apparatus.*

February 5, 1894.

2,451. C. R. G. SMYTHE, Glasgow. Improvements in, and connected with, electrical concentric conductors.

2,452. F. W. CROSSLEY and J. ATKINSON. Manchester. Improvements in thermo-dynamic motors.

2,487. C. J. HALL. London. Improvements in, or relating to, secondary batteries.

2,493. R. F. RANDELL. London. Improvements in holders for electric incandescence lamps.

2,514. J. H. WEST. London. Improvements in, or relating to, electric bells.*

2,524. BLACKMAN VENTILATING COMPANY (LIMITED). London. An electromotor for fans. (F. Stahl, Germany.)

February 6, 1894.

2,548. H. V. KEESON. London. Improvement in firing keys or electrical contact makers

2,562. F. M. ASHLEY. Manchester. Improvements in electrical tramways and railways.

2,607. R. FLEBBE. London. An improved magnetic electric conduit system for electric tramways, railways, and the like.

2,623. W. M. MORDEY. London. Improvements in regulating and controlling dynamos.

February 7, 1894.

2,677. C. A. BECK and L. KAMM. London. An improved printing telegraph and transmitter.

2,693. E. O. KUMBERG and B. E. CLARKE. London. Improvements in or connected with phonographs.

2,721. T. SEWELL and H. BODTKER. London. Improvements in and connected with insulators for supporting electric telegraph, telephone, and similar conducting wires.

February 8, 1894.

2,542. T. FIELD and C. SURETIES. Improvements in and relating to the manufacture of plates for engraving and electrotyping purposes.

2,730. T. B. GRANT. London. A new and improved protector for electric cables laid underground.

2,733. W. C. MOUNTAIN and G. T. O'B. CAREW. Newcastle-on-Tyne. Improvements in or relating to the regulating mechanism of electric arc lamps.

2,734. J. H. KERR. Dublin. An improved electrical contact screw.

2,749. D. DENISON. Bradford. A new or improved register and holder therefor for recording telephonic messages.

2,790. F. KLEGE. London. An improved electric-registering apparatus for recording the speed and occupation of vehicles.

2,800. E. F. A. SOLEAU. London. Improvements in incandescent lamp fittings.

2,805. C. KELLNER. London. Improvements in electrolytical decomposing apparatus.

2,812. N. TESLA. London. Improvements in methods of and apparatus for the generation of electric currents of defined period. (Date applied for under Patents, &c., Act. 1883. Sec. 103, August 19, 1893, being date of application in United States.)*

February 10, 1894.

2,851. W. P. THEERMANN. Manchester. Improved electric signal apparatus.

2,866. W. L. WISE. London. Improvements in and having relation to dynamo-electric machines. (J. N. Lewis, United States.)

2,897. C. P. SHREWSBURY, F. L. MARSHALL, J. COOPER and J. L. DOBELL. London. Improvements in the manufacture of coke or carbon for electrical or other purposes.

2,930. J. RUDHOLZNER, London. Improvements relating to the electro-deposition of metals.

2,936. A. B. BROWN, Glasgow. Improvements applicable in connection with telemotor apparatus for actuating mechanism at a distance for telegraphing, indicating steering, and analogous purposes.

2,965. J. H. GEISENHEIMER and E. A. LESSING, London. Improvements in holders for incandescent electric lamps.

2,968. O. IMRAY, London. An improvement in electrolysing liquids and apparatus therefor. (The Farbwerke vormals Meister, Lucius, und Brüning, Germany).

2,976. H. V. LANCHESTER. London. Improvements in casings and fittings for electric wires and fittings.

February 12, 1894.

2,990. T. PARKER. Wolverhampton. Improvements in electric tramways.

3,013. S. A. MAHOOD. Hanley. Improvements in apparatus for drawing through electrical or other cables or conductors in underground pipes or conduits.

3,020. F. TUDSBURY. Sheffield. Improvements in induction electrical machines.*

3,035. S. MACDONALD. London. New or improved electrically-operated instrument for tattooing the skin.

3,045. L. BÄÄRNHIELM and A. JERNANDER. London. An improved insulating compound.*

February 13, 1894.

3,052. J. W. EWART. London. Improved method of advertising by means of an electric lamp.

3,056. A. MARR. Manchester. Improvements in, and relating to, electrical safety fuses.

3,072. J. E. WOOLVERTON. Glasgow. Improvement in arc lamps.*

3,079. H SANDERS. Birmingham. An electric bell indicator.

3,080. W. P. THEERMANN, W. CROOKELL, and G. C. ELLIOTT. Manchester. Improved method of fixing electric call bells.

3,101. W. B. SAYERS, H. A. MAVOR, W. A. COULSON, and S. MAVOR. London. Improvements in armatures for dynamo-electric machines.

3,108. P. W. LEFFLER and E. CORRIGAN. London. Electric railways.*

3,109. J. IMRAY. London. An electric locomotive for combined adhesion and rack traction. (F. Rinecker, Germany).

3,111. R. HADDAN. London. Improvements in electric signalling devices. (A. S. Williams, United States.)*

3,118. I. A. TIMMIS and A. J. SMITH. London. Improvements in the regulation of electric motors.

3,125. O. DUFAULT. London. Improvements in armature connections for dynamos.

3,130. L. B. MILLER and M. W. WOODS. London. Automatic cut-out or regulator.

February 14, 1894.

3,155. W. WILLIAMS and T. B. JOHNSTON. Bristol. Combined casings and insulators for electric wires.

3,166. J. B. HOWARD. Halifax. Improvements in underground conductors of electrical tramways. (W. Simon, W. Beissbarth and J. Beissbarth, Germany).

3,217. H. F. JOEL. London. Improvements in electric arc lamps.

3,223. W. DONALDSON. London. Improvements in heating of gases by electricity.*

3,234. W. C. BERSEY, E. J. CLUBBE, and A. W. SOUTHEY. London. Improvements in the locking mechanism of common road vehicles propelled by electromotive or other power.

February 15, 1894.

3,245. D. COOK. Richmond. Improvements in lead-covered electric cables.

3,273. A. CHESTER and J. J. RATHBONE. London. Improvements connected with arc lamps.*

3,277. G. H. NISBETT. London. Improvements in the construction and methods of manufacture of electrical cables.

3,291. A. W. MONEY and H. NASH. London. Improvements in electric arc lamps.

3,294. M. PETERSON. London. Improvements in electric lighting apparatus for gas burners.

3,312. H. H. COOPER and THE ELECTRICAL INSTALLATION COMPANY (LIMITED). London. Improvements in electric arc lamps.

February 16, 1894.

3,363. S. S. ALLIN and W. H. WOOD. London. Improvements in arc lamps.

3,376. J. B. HOLROYDE. Manchester. Improvements in appliances or means for securing the covers to the casings of electric-light wires, applicable also to other purposes. (C. J. Holroyde, Australia.)

3,384. J. W. TURNBULL. London. Improvements in incandescent electric lamps.*

3,399. W. LANGDON-DAVIES. London. Improvements in apparatus for obtaining a rotary magnetic field.

February 17, 1894.

3,422. W. ROCKLIFFE. Newcastle-on-Tyne. Improved method of, and means for, generating steam by electricity.

3,425. D. HUNTER and W. A. JACK. Glasgow. Improvements in electric lamps, and in the holders or sockets therefor.

COMPANIES' MEETINGS AND REPORTS.

City of Bath Electric Lighting and Engineering Company (Limited).

The annual meeting of this Company was held on Wednesday, at the offices, Dorchester-street, Bath. Mr. T. O. Callender, Chairman of the Company, presided.

In moving the adoption of the report, which appeared in our last issue, the CHAIRMAN said the Directors were sorry they could not recommend the declaration of a dividend, but they felt this satisfaction, that the business of the future would proceed in a much more satisfactory way than in the early part of last year. All the Company needed was an extension of the number of customers. Their regular standing charges and those incurred by the running of the machinery were heavy, whether they supplied many or few lamps, and they had got to this point now that additional extensions would mean a source of considerable profit. He felt it would be a satisfaction to the shareholders to know that the Company's plant was capable of supplying a very much larger number of lamps, that their mains ran past the doors of most houses in the City, and that all they now wanted was a larger number of citizens to adopt the illuminant. The Directors had found that the old contract system did not work out satisfactorily, and the meter system which had been substituted was considered on all hands to be the fairest and best. It was certainly no injustice to the consumer, for now each customer got what he paid for, and the immense waste formerly existing had been stopped. Alluding to the accounts, he pointed out that while the revenue of the Company had considerably increased, their expenses remained the same. Many alterations had been carried out at the works: Mr. Metzger had been appointed engineer and manager, and the Directors were glad to say that, with his assistance, considerable economies and improvements had been effected. The machinery and plant had also been thoroughly improved, and the station was now in a much better condition than it had eyer been. There had been several changes in the Board of Directors, several having retired, while Mr. B. H. Van Tromp and Mr. J. B. Wood had been elected. The Board was now

much smaller than previously, but the business was proceeding satisfactorily.

Mr. VAN TROMP seconded the motion, which was carried unanimously.

Mr. E. B. TITLEY moved the re-election of the retiring Directors, which was seconded by Mr. SIMPSON, and carried; and Mr. Butcher having been re-elected auditor, the meeting terminated.

Yorkshire House-to-House Electricity Company (Limited).

The first annual meeting of this Company was held on Tuesday at the Central Electric Lighting Station, Whitehall-road, Leeds. Mr. Grosvenor Talbot (Chairman) presided.

The CHAIRMAN, in moving the adoption of the report (which appeared in *The Electrician* of the 23rd ult.) said that since their meeting of May 12th last year the Directors had had not only a busy and laborious time, but a time of considerable anxiety. They had to establish the Company, and they had suffered anxiety on account of the constant increase in their plant that was necessary. On the work of the last eight months they had been able to show a profit of £1,155, which was, he believed, different to what most electric lighting companies had been able to show for so short a period of working. That was most satisfactory to them considering that the months of May, June, July, and August, were the months of the longest days, when lighting was little required. They had only four months of really good lighting, and they certainly had not done badly in making the profit they had done. He trusted that the way in which they had disposed of the profits would meet the approval of the shareholders. The Directors had thought it better that they should reduce the amount of the preliminary expenses account, and they had applied £1,000 for this purpose. He did not think that in another year they would be called upon to apply a similar amount. They had had to contend with two difficulties. There had, in the first place, been one of the brightest winters and autumns on record, which meant a great many hours less lighting; and then there was the coal strike. But they felt that, after all, they had not made a bad record during the last eight months. The lamps had been put in in small numbers until they got to the maximum amount in the dead of winter, and they had found that unless they took the proper steps they should not be able to supply their customers. In Leeds the number of lamps burning was, compared with the number of lamps in store, larger than in any other district. In other stations they reckoned to have twice as many lamps as they had burning, but in Leeds they had three-fourths of their lamps going at the same time. Referring to the increase in the horse-power mentioned in the report, the Chairman said it became necessary for the Directors to consider what would be their position in the following winter, for they knew that there were several large buildings in course of erection in the city which were depending upon electric lighting directly they were opened. It had been growing upon the Directors month after month that the value of the site of the station was almost incalculable; it was in such a wonderfully good position, close to the centre of the town, and they felt the necessity of making the best use of that excellent site. They had made the Corporation an offer to supply the Town Hall and the municipal buildings with electric light at a considerably less cost than appeared in the published accounts of the County Council. Some of their customers had suggested that the price of electricity was high, but they intended next April to reduce the price by 12½ per cent. They felt sure that their customers would realise the benefits of electric lighting, that they would find that they were not only getting a better light, but that their decorating and painting bills were considerably less than when gas was used. He confidently believed that the price of electricity, paradoxical as it may seem, lay more in the hands of the inhabitants of Leeds than with the Directors, because with a progressive demand they should be able to give successive decreases until they got it down to a reasonably small figure. The initial expenses of starting the electric lighting station had been heavy, but afterwards the decrease was most remarkable. They had made a very fair start, and he had confidence that they should be able to have in Leeds a large, paying, and thrifty electric lighting establishment.

Mr. G. H. CROWTHER seconded the motion for the adoption of the report, and it was carried.

Mr. Samuel Ingham and Mr. Arthur Greenhow Lupton were re-elected Directors of the Company, and Mr. John Gordon, jun., was reappointed auditor; and the meeting closed with a vote of thanks to the Chairman.

Scarborough Electric Supply Company (Limited).

The second ordinary general meeting of this Company was held at the offices, Westborough, Scarborough, Lieut.-Col. Steble in the chair.

The CHAIRMAN, in moving the adoption of the report (which appeared in our issue of the 23rd ult.), said that last year at this time the Company had not a brick laid. Now their supply station was in full working order, and two engines were generating electricity equal to 5,000 c.p. They had accommodation for five more engines and one boiler when they needed them, and therefore they were fully prepared to make the additional supplies of electric light which they might fairly anticipate in the near future. He congratulated the Company on the success it had so far attained, and said that the favour in which the illuminant the Company supplied was held was still spreading. He emphasised the growth of the supply since September 1st, as set forth in the annual report, and said that the business they were doing was extremely satisfactory for a small Company like theirs. The current supplied represented a revenue of £370, less discount, and that was a satisfactory return towards the expenditure upon the generating plant. The Company's capital expenditure had been about £20,000. That, he thought was very small, considering that it included the cost of mains and cables. They had now 5½ miles of mains, and nearly 18 miles of cables laid. He hoped that before very long they would require more machinery, and if that were so they would require more capital. It would be for the Directors to consider how this should be raised, and it might be that they would issue debentures to cover the cost. He was looking forward with some confidence to the day when electricity would not only benefit Scarborough and the Company materially, but also benefit the health of the borough. In saying that he was thinking of the experiments which were now being made in utilising town refuse for the generation of electricity instead of coal, and anticipated a favourable result. If the experiments should succeed, and they were able to generate electricity in that way, the Company would, of course, supply the light at a much cheaper price than they were now doing. They were now charging from 5¾d. to 6½d. per unit, less 5 per cent. discount on accounts settled within a reasonable time, and he was not without hope that before very long they would be able to make a little further reduction in prices to consumers and also make a return to the shareholders. It was not to be anticipated that in the first year the Company would be able to pay anything in the shape of interest to the shareholders, and he thought they would be thankful to know that the income balanced the working expenses.

Mr. A. A. CAMPBELL SWINTON seconded the motion, and said that the question of dividend was the one that probably interested the shareholders most. The receipts amounted now to £125 per month and just about balanced the expenditure. With the addition of 2,000 or 3,000 more lamps, therefore, the Company would be in a fair way of paying a dividend. It was difficult, however, until they had been working one year to make accurate calculations. There was no doubt that it was to the interest of the Company to make the electric light as cheap as possible, and for that reason it was important, too, that consumers should remember that the lamp patents had expired, and that very much more efficient lamps could now be obtained than was previously the case. Of course the less efficient the lamps were the more electricity would be consumed, and therefore the least efficient lamps would in one sense be an advantage to the Company. On the other hand, the better the light the more likely would its use extend, and therefore the Company recommended consumers to use the most efficient lamps, which could now be obtained to give the same amount of light for two-thirds the amount of current that was used before the expiration of the patents. He recommended the high-efficiency lamps, and said that though they did not last quite so long as the old lamps, the cost of renewal was very small as compared with the cost of the current. The machinery at the Company's generating station had been working satisfactorily. The amount expended on capital almost exactly corresponded with the original estimates, the only difference being that they had laid rather longer mains than originally planned.

The motion was adopted.

On the motion of Mr. WILKINSON, Mr. G. L. Beeforth, the Hon. C. A. Parsons, and Mr. G. Alderson Smith were re-elected as Directors; and the auditor having been re-appointed, a vote of thanks to the Chairman concluded the meeting.

Morecambe Electric Light and Power Company (Limited).

The third annual meeting of this Company was held at Morecambe last week, Mr. C. Mabbott presiding. The report, an abstract of which appeared in our last issue, was adopted, and a dividend of 2 per cent. declared. It was stated that but for the temporary suspension of service by fire this would have been increased to 5 per cent. Mr. W. B. Hodgson was re-appointed a Director, and Mr. James Duff (Halifax) re-elected auditor.

The engineers in their report stated that the Company had been the pioneer of a new system of electric lighting generated by means of Dowson gas made on the premises, and that the economical system adopted at their works had resulted in not less than six public authorities adopting the same system, by which electric light could be generated and supplied at a price consumers could afford to pay.

Isle of Man Tramways Company (Limited).

A meeting of the shareholders in this Company was held on Friday, at Villier's Hotel, Douglas, for the purpose of approving the sale of the undertaking and assets of the Company to the Douglas and Laxey Electric Tramway Company for £38,000. Mr. Pittar, chairman, presided. It was explained that the dividend declared in December last had to be deducted from the sum offered; £1,400 was set aside for the expenses of winding-up the Company and compensation to such officials as the Board decided were to receive it, leaving £35,000 as assets divisible amongst the shareholders. The Ordinary shareholders were entitled to all the profits after payment of the Preferential dividend of 6 per cent. The Preference shareholders were entitled to repayment of their capital of £10,000 at par, and the balance of £25,000 would be divisible exclusively amongst the Ordinary shareholders, of which there were 16,000 odd, which would be equal to £1. 10s. 4d. per share.

The CHAIRMAN explained that the Directors, who held about one-fifth of the shares, strongly recommended that the offer be accepted.

Mr. A. BROWN moved that the offer be accepted, and pointed out that the purchasing Company agreed to take over the liabilities, amounting to £3,100, so that they were practically paying £41,000 for the concern.

Although considerable dissatisfaction was evinced at the proposed sale by the Preference shareholders, the motion was carried by a large majority.

Oriental Telephone and Electric Company (Limited).

The following has been issued to the shareholders of this Company, under date February 23rd :—

"At the extraordinary general meeting of the Company, held on the 21st inst., the resolutions referred to in the accompanying notice were considered, and the result of a poll taken upon them showed that the votes in favour of the scheme amounted to 49,756, and in opposition thereto 1,116. The Directors did not vote in the poll, nor did they use the proxies which they had received, which carried further votes amounting to 90,597. Had the Directors voted and used the proxies held by them, the total votes in favour of the scheme would have amounted to 198,544."

An extraordinary general meeting of the members of the Company will be held on Monday next, March 12th, at 1, at the Cannon-street Hotel, E.C., when the resolutions which were passed at the extraordinary general meeting, held on the 21st ult. (and set out in *The Electrician* of the 16th ult., p. 437), will be submitted for confirmation as special resolutions.

Hove Electric Lighting Company (Limited).

The following report of the Directors is to be presented at the annual general meeting of the shareholders at the Town Hall, Hove, near Brighton, on Wednesday next, the 14th inst., at three o'clock :—

This statement covers the whole period since the formation of the Company in August, 1892, and is intended to supersede the interim statement submitted to the members on December 12th last. The Directors have pleasure in again congratulating the shareholders on the progress of the Company. The number of lamps attached to the Company's main is now equal to 6,915 8-c.p. lamps, and the number of houses has increased to 105. The working of the Company has resulted in a small profit at December 31st last, and from the increasing number of new customers and additional lamps connected each week, the Directors look forward with confidence to a very satisfactory profit at the end of the current year. The opposition Company—the Brighton and Hove Electric Lighting Company—who are supplying a certain number of consumers in Hove with electric current from overhead wires, have been directed by the Board of Trade to make certain alterations in their system of conductors, but they have, it is believed, decided to discontinue their operations in Hove altogether, and consequently your Directors expect a large accession of lights to their system shortly. Indeed, at the present moment, they have applications from consumers with nearly 3,000 additional lights.

Since the date of the interim report the Directors have allotted 756 additional shares, bringing up the total allotted to 4,046 shares, representing a subscription of £20,230, while the capital expenditure amounts to £29,235, and consequently there are large balances due to the contractors and others, in addition to which the Company's further commitments on capital account amount to nearly £13,000. It is, therefore, necessary that further subscriptions for capital be obtained, and the Directors urge upon the members to subscribe for the balance of the Company's shares.

Colonel A. J. Filgate and Colonel H. Wood, C.B., retire from the Board by rotation, and being eligible, offer themselves for re-election, as does Mr. Robert Payne, F.C.A., the auditor.

NEW COMPANIES, STATUTORY RETURNS, &c.

In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, *pages* 274-300, *&c., &c.*]

ELECTRIC WELDING COMPANY (LIMITED).—The annual return of this Company, made up to December 31, last, was recently filed. The nominal capital is £460,000, divided into 45,000 Ordinary and 1,000 Founders' shares of £10 each. 25,000 Ordinary and 948 Founders' shares have been taken up, of which 8,333 were issued as fully paid. Upon the remaining 16,667 Ordinary shares a call of £6 per share has been made, and upon the 948 Founders' shares the full amount has been called. The calls paid have amounted to £116,339, leaving £29,143 in arrears.

EASTERN TELEGRAPH COMPANY.—The annual return of this Company, made up to February 8, has been filed. The nominal capital is £4,700,000, divided into 400,000 Ordinary and 70,000 Preference shares, of £10 each. 469,988 shares have been taken up, the full amount called, and all calls paid in full.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—Notice is given that the transfer books of this Company will be closed from the 15th to the 21st March inclusive, preparatory to paying an interim dividend of 3s. per share, being at the rate of 6 per cent. per annum for the half-year ended December 31st, free of income-tax, payable on the 22nd inst.

CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).—Subscriptions are invited for 6,000 Six per Cent. Preference shares of £5 each in this Company, issued at a premium of 10s. per share, payable 10s. on application, £1. 10s. on allotment (including the premium of 10s.), £1. 10s. on April 16th, £1 on August 15th, and £1 on December 15th. The additional capital is required (the prospectus states) for the extension of mains into a fresh district in Chelsea, and to defray the cost of the buildings, works, and machinery necessary to enable the Company to deal with the increasing demand for current, &c. The accounts for 1893 show a net balance of £3,105. 2s. 7d., and a dividend of 5 per cent. has been declared on the Ordinary shares for the past year. The prospectus shows that a steady improvement is apparent in the position of the Company. During the past year 10,665 additional lamps have been joined up, making the total number of 8-c.p. lamps connected to December 31st last 40,665. Applications for shares must be made on the form accompanying the prospectus, which can be obtained at the offices of the Company, Draycott-place, Chelsea, London, S.W. ; of the London and South-Western Bank, Sloane-square, S.W., and 170, Fenchurch-street, E.C. ; or at the offices of the Electric and General Investment Company (Limited), 1 and 2, Great Winchester-street, E.C. The list opened on Tuesday last, and closes on Tuesday next at 4 p.m., for both town and country.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—It is announced that, in response to the application for £100,000 Five per Cent. Debenture Stock, made last week, applications amounted to no less than £1,288,835. Letters of allotment and regret were posted on Wednesday evening.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended March 4th were £934, as against £929 in the corresponding period of last year, being an increase of £5. The total receipts for the half-year amount to £8,544, as against £8,672 for the corresponding period of last year, a decrease of £128.

COMMERCIAL CABLE COMPANY.—A quarterly dividend at the rate of 7 per cent. per annum has been declared by the Directors, payable on April 2nd.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of February are £3,600, as compared with £3,765 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of February amounted to £1,698, as against £1,808 for the corresponding period of 1893.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the month of February amounted to £54,904, as against £55,281 in the corresponding period of last year.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of February amounted to £35,187, as against £39,533 for the corresponding period of 1893.

EDINBURGH AND DISTRICT TRAMWAYS COMPANY (LIMITED).—The question of the transfer of the agreements between the Corporation of Edinburgh and Messrs. Dick, Kerr and Co. (Limited) appears to have been settled, as the prospectus is now issued of the above Company, which is formed to acquire the lease which the Corporation came to with Messrs. Dick, Kerr and Co. for a period of 21 years from the 9th December last. The lines comprise about twelve miles of tramways. The capital of the new Company is £117,500 in 20,000 Five-and-a-Half per Cent. Cumulative Preferred shares of £5 each, and 17,500, Deferred of £1 each. Messrs. Dick, Kerr and Co. continue to work the tramway during the continuance of the lease, paying to the new company all receipts in return for their providing all necessary funds and plant for the purposes of the undertaking.

ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL COMPANY (LIMITED).—In our issue of February 23rd publicity was given to a circular issued to the shareholders, in which the Directors announced that, unless £5,000 was subscribed by the shareholders, the Directors would be compelled to create £30,000 in Preference shares. In accordance with this notification a circular is now issued, in which the Directors regret that the £5,000 had not been subscribed, and that, therefore, they have no alternative but to proceed with the issue of the £30,000 Preference shares. At the same time they announce that a contract has been entered into with the German Imperial Marine for a three years' supply of all the copper tubes between 7in. and 12in. diameter that may be required at the Government Docks at Wilhelmshaven, Kiel, and Dantzic. "It is, therefore, imperative that the Company should be strengthened financially, in order to be able to carry this contract into effect."

ELMORE'S WIRE MANUFACTURING COMPANY (LIMITED).—It is stated in the financial papers that the recent issue of £30,000 Preference Stock of this Company has all been placed, and that Mr. Edward Reynolds (of Vickers, Sons and Co., Limited) has joined the Board of Directors.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for February, 1894, amounted to £20,000, and from January 1st to February 28, 1894, to £41,000. In the corresponding months of 1892 and 1893 the amounts were £40,800 and £41,200 respectively.

HOBART ELECTRIC TRAMWAYS COMPANY (LIMITED).—For the month of February the receipts were £1,431.

STOCK EXCHANGE NOTICES.—Applications have been made to the Stock Exchange Committee to allow the following securities to be quoted in the Official List :—General Hydraulic Power Company (Limited), further issue of 10,000 shares (1892), Nos. 80,001 to 90,000 ; National Telephone Company (Limited), further issue of £74,983 Four and a-Half per cent. Debenture Stock.

UNITED ASBESTOS COMPANY (LIMITED).—The Directors of this Company recommend the payment of the following dividends for the past year :—10 per cent. on the £10 Preference shares, 6 per cent. on the £5 Preference shares, and 2½ per cent. on the Ordinary shares, carrying forward a balance equal to 5¾ per cent. on the Ordinary shares.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 826.—Vol. XXXII. FRIDAY, MARCH 16, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

In the brief but highly practical discussion which followed the reading of Major-Gen. Webber's paper at the Institution of Electrical Engineers, Mr. Alex. Siemens, it will be remembered, took up the cudgels on behalf of armoured cables for distributors, at any rate so far as the City of London was concerned, pointing out that they "could be threaded in under or over the gas and water pipes" without any difficulty, and that they were exempt from what the daily press is pleased to call "electric lighting explosions." In the Paper read on Monday last before the Northern Society of Electrical Engineers, Mr. J. H. Rider corroborates this opinion, supplementing it by another in favour of the use of a "draw-in" system for feeders. Mr. Rider points out that electric light mains can now be calculated so as to meet future as well as present requirements; hence the hitherto insuperable objection to armoured cables, namely, that the streets must be frequently opened up, is no longer valid. Should the demand, however, increase so unexpectedly in any given district or street as to render the fall in volts along the distributors too great to be permitted, the simplest way out of the difficulty, Mr. Rider argues, would be to run another feeder, which, of course, involves a network of feeders on the "draw-in" system. The objection, however, raised by Mr. Clirehugh, in the Paper read at the same meeting of the Northern Society, that it is more difficult to localise and repair faults where armoured cables are concerned, than in the case, say, of cables run in iron pipes, is one which must not be lost sight of. Nevertheless, Mr. Rider's preference for armoured cable distributors, and "draw-in" feeders, the converse of the usual arrangement, appears to be well supported by practical reasoning.

At a recent meeting of the Bristol Electrical Committee, some revisions in the system of charging for electric energy were made, with a view to encouraging increased consumption. The decision that between midnight and one hour before sunset energy should be charged for at a lowered rate, is based on sound principles; but the same cannot be said for the arrangement which was made to grant heavy discounts on a sliding scale to large consumers. Customers from £50 to £100 are to have 5 per cent. rebate; from £100 to £250 they will receive 10 per cent. rebate; while reductions to the amount of 20 per cent. are promised. We have several times shown the fallacy of making rebates on any such system as this. The large consumer may be a boon or a nuisance to the supply corporation; but in ninety-nine cases out of a hundred he is the latter. Large consumption, *per se*, is, of course, a boon, but one cannot have large consumption where there are not many lamps or large motors; and there is nothing to show that the large consumer consumes at a greater rate, in proportion to the lamps he has wired, than the small consumer does. The sort of customer that Bristol and other electrically supplied towns will find it advantageous to encourage is not necessarily the large consumer with his big bill, but the consumer whose bill is large in proportion to the lamps he uses, however small that bill may be in actual £. s. d.

In the current number of *Wiedemann's Annalen*, Herr du Bois describes a ring magnet, by the aid of which he has attained a field of 38,000 C.G.S. units in air over a space of several millimetres; and has attained in iron an induction density of 60,000 C.G.S. units, which we believe to be the highest value yet observed. In such a field the resistance of a bismuth wire would be tripled. The most interesting experiment in these cases would be to take the B—H curve of the iron wire, in order to determine whether it had become parallel to the line denoting H in the air. When this parallelism is attained, all the Ewing molecular magnets would have been turned parallel to the axis of the wire. It is, however, probable that the number of magnets is extremely large, and consequently the magnetising force to produce this result would have to be almost infinite. Herr du Bois does not appear to have experimented in this direction.

One of the most interesting features of the Scarborough electric supply, which is described elsewhere, is the use of large buried transformers, a compromise between the wasteful house transformer system and the complicated and expensive sub-station system. The encouragement given by the former to mulct consumers for transformer "rental," and by the latter to suggest an intricate automatic switching gear, are absent. The system, which is receiving attention in several other towns, seems to be very sensible, and ought not to be difficult to carry out, even in crowded streets.

We turn with interest, every week, to the "Electric Lighting Memoranda," as well as to the other columns of our contemporary, the *Journal of Gas Lighting*, a publication to which

Digitized by Google

we have often referred, and one in which our readers will often find useful information as well as candid criticism. The two articles on Tests of Gas-burners and the supplementary one on Comparative Cost of Lighting by Gas and by Electric Light, which appeared in our columns at the end of last year, have been recently reprinted in our contemporary. These, as was natural, were criticised in a succeeding number. The criticism exhibited a remarkable departure from the usual fairness of our gas contemporary, and contained several misrepresentations, which we did not think worth noticing at the time. Finding, however, a repetition of these perversions in the last issue of the *Journal of Gas Lighting*, we are compelled to put our contemporary right on one or two points. "Exception may be taken," it was remarked in "Electric Lighting Memoranda" of February 27th, "that there are in nightly use in all parts of the world, thousands of economical high-power gas-burners of patterns not included in the selection dealt with in this report." Thousands of burners, not thousands of varieties are, of course, meant. This we readily admit, and confess that we were surprised to find that Prof. Ayrton's students had not included, for example, any "Peebles," "Cromartie," "Christiania," or Heron's burners, but in the first set of tests, no less than twenty-six burners were examined, besides 30 and 80-c.p. Bray's, and Wenham, Albo-Carbon, Argand, and Welsbach. In the summary of results, twenty-seven burners were included, and in the table of the cost of a candle-hour, twenty-eight sets were given. Of these we selected the first twenty-two, "omitting the last six burners, which are of large candle-power and high efficiency." These were Bray 30 c.p. and 80 c.p., London Argand, Wenham, Albo-Carbon, and Welsbach. On the *average* of these twenty-two the whole of our comparison was founded.

We intended to compare ordinary gas burners with ordinary electric light. Had we included arc lamps, of course, gas would have been nowhere, light for light. In our issue of December 8th, p. 143, a table was given showing graphically the comparative cost of lighting by means of lines of different lengths. We gave three lines for gas burners, these were the worst, the average of twenty-two, and the Argand. After these three we gave nine lines for glow lamps under different conditions. The first of these was an 8-c.p. lamp at 4 watts per candle, and at 6d. per unit. Now everybody knows that several of the London supply companies charge 8d. per unit, and at Eastbourne and Hastings and elsewhere this is exceeded; further, the general custom, before the expiry of the lamp patent, was to run lamps at nearer 5 watts per candle than 4, and that competition in price, light for light, with gas at 2s. 6d. is then out of the question. We began with the case to which we have alluded, and this gave practically the same cost as the worst gas burner. The general comparison was, of course, with the average of twenty-two burners, and we showed that, contrary to the enthusiastic estimates of many electricians, real competition in price does not begin until we run 16-c.p. lamps at 3 watts per candle, with supply at 4d. per unit, or at 2½ watts per candle at 5d. per unit. The last line on our diagram referred to a 16-c.p. lamp at 2½ watts per candle with supply at 4d. per unit. The cost under these conditions is more than 16 per cent. less than gas at 2s. 6d. consumed at the average rate of these twenty-two burners.

Our contemporary accuses us of starting "with an utterly unfair and unpractical datum, consisting of the calculated cost of gas-lighting by a No. 1 flat-flame burner." We did nothing of the sort. Throughout the article, we referred solely to the average of 22 as our datum. "This old trick," says our contemporary, "of rating gas light at the worst effect which can be forced upon it by carefully selecting the most unsuitable burner that offers itself for the purpose, and comparing the result with such an ideal of electric lighting as that imagined in the purely supposititious combination of a 2½-watt lamp with current at 4d. per unit, has surely been played often enough. . . . It might be asked why, if the articles in question were so vitiated by having a false conclusion forced upon them, we reproduced them in these columns. The answer is that if we were to ignore these exercises of the electrician we should lie under suspicion of being afraid of what they say. It is policy to give them all the publicity they crave; and then, if their utterances prove worthless, their discredit is all the greater." This and more abuse is offered, but the above is enough. How did we deal with the 2½-watt lamp? We wrote that "we are now hoping to find a 2½-watt lamp." This is a different thing from saying that we had found one, and still more different from taking it as a basis of comparison. But lest this should be thought ambiguous, we distinctly wrote, "we must for the present discard the 2·5 watts per candle. It is true that we have promises, and, indeed, offers of such lamps, and a guarantee of one at 2s., but we have no experience as to their life." This is sufficient to turn the tables completely against our critics, and we cast their own words at them, for "if their utterances prove worthless, their discredit is all the greater."

We made the comparison with the full knowledge that it is only under exceptional circumstances that glow lamps can compete with ordinary gas burners, and knowing the uncertainty of the life of lamps, and that we were considering examples of three watts per candle, we put the lamp renewals as high as 6s. per 1,460 hours. This is equivalent to 486 hours for a 2s. lamp, 365 hours for a 1s. 6d. lamp, or 243 hours for a 1s. lamp. We took no account of the incidental economies of electric lighting, and stated the case as impartially as possible. Of the nine examples of glow lamps used under different circumstance, only two came out at a lower cost than that of the average of 22 gas burners, and one of these is to be discarded for the present, as we clearly stated, because it is run at 2½ watts per candle. The *Journal of Gas Lighting* is generally fair, but on this occasion either gross carelessness or something worse—something, however, perhaps, not quite so bad as that of which we are accused—has led it into a flagrant example of "cooking by gas."

We are glad to record that our present issue has been edited under the genial beams of the electric light. We have waited long and patiently for it.

Technical Education.—Lord Norton has given notice that on an early day he will move for a return of the various modes in which the Technical Education grant is being administered by County Councils receiving a share of it.

Cable Interruptions:

	Date of Interruption.
Cayenne-Paramaribo	Oct. 15th, 1893.
Bissao-Bolama	Nov. 24th „
Garachico-Santa Cruz de Palma	Dec. 27th „

Leeds Association of Engineers.—At the last monthly meeting of the Leeds Association of Engineers a Paper was read by Mr. C. J. Hall on "The Generation and Distribution of Electricity." Mr. Hall reviewed the various systems of electric distribution of power which have come into use.

Prize Competition for Electric Light Schemes.—The 100-guinea premium offered by the Corporation of the small Yorkshire town of Morley for the best scheme of Municipal Electric Lighting Works for the borough has been awarded to Mr. Robert Hammond, who competed under the pseudonym of "Lux et Felicitas."

The Telegraph in British North Borneo.—The Eastern Extension Telegraph Company have just agreed to connect Borneo with Labuan by a branch cable, and the Directors of the British North Borneo Company have decided to connect Sandakan, the capital of their territory, by telegraph and road across country, a distance of over 200 miles. The work will be completed within a few months.

Telephony between Berlin and Trieste.—Some experiments have been made on a line formed by coupling to one another the Trieste-Vienna-Prague-Reichenberg-Zittau-Berlin lines, a total distance of some 600 miles, when it was found that although a melody was easily transmitted, speech was not very distinct. The experiments are considered to be so promising as to raise afresh the question of the desirability of telephonic communication over this route.

The Electric Lighting of the Embankment.—The Highways Committee of the London County Council at the meeting on Wednesday, again brought up a recommendation for the lighting of the Embankment by lamps in the centre of the carriage way.—Mr. Roberts moved, and Mr. J. W. Benn, M.P., seconded, that, in the opinion of the Council, it was undesirable to place lamps in the centre of the carriage way. —After some discussion a vote was taken and the amendment carried.

Electric Lighting at Windermere.—At Troutbeck Bridge, between Windermere and Ambleside, a small electric light works has been established. A turbine, 6ft. 6in. in diameter, has been erected, supplanting an old and cumbrous 35ft. water-wheel. This furnishes the motive power for the dynamos, and there is provision for the water power being supplemented, or on occasion superseded for the time being, by steam power in the event of a temporary failure in the water supply. Last week a connection was completed between the works and the Low Wood Hotel.

"Elektron."—This is the title of a new monthly magazine hailing from Boston, and "devoted to electricity and its allied interests in their scientific and practical aspects." The first number is, for the most part, made up of short articles written in a more or less popular style, amongst which we may mention an article on "The Electro-Magnetic Theory of Light," by Prof. Dolbear; "The Buoy-Lighting of the Water-way to the World's Fair," by Commander J. J. Brice; and a reprint of Prof. Silvanus Thompson's review of the Chicago Congress, which originally appeared in these columns.

Railway Shunting by Electricity.—At the new textile machinery works of Messrs. Tweedale and Smalley, Castleton, near Rochdale, electric shunting on their railway siding and electric hoisting have been adopted. The raw goods, says *Industries and Iron*, are backed into the siding by the railway engines, and are then taken wherever required by an electric locomotive, worked on the overhead-wire system. The packing-room is provided with an electrical crane for hoisting the machinery either into railway trucks or on to waggons. The electrical energy is generated by a dynamo situated in the main engine-room, and driven from the works engine, which is of the horizontal tandem compound type.

Addition by the Slide Rule.—For those whose powers of mental calculation have become atrophied in consequence of the use of the slide rule, the following hint may be of use. Consider the following equations $a:b=1:x$ and therefore $a:a+b=1:1+x$. In these equations lies the method of adding two numbers by the slide rule. The first proceeding is to set the slider with its unit on the a of the scale; then b on the scale is opposite x on the slider. Add 1 to x mentally, and read opposite $(x+1)$ on the slider the value of $(a+b)$ on the scale. The method is equally applicable to subtraction, and the principle is easily grasped and extended. We are indebted to Prof. Ritter for the idea. We have tried this method, and find that it "works," but we fail to appreciate its utility.

Northern Society of Electrical Engineers.—The discussion which followed the reading of Messrs. Rider's and Clirehugh's Papers, abstracts of which will be found in another column, was adjourned to the next general meeting, to be held on Monday, April 9th, and was taken part in by the following gentlemen:—Messrs. Wordingham, A. B. Mountain, W. Fox-Bourne, J. Connolly, E. W. Cowan, L. Andrew, and R. Taylor. The following new members were elected:—Geo. Broughall (Manchester Edison-Swan Company), T. B. C. Nuttall (Siemens Brothers), A. Oughterson (W. T. Glover and Co.), F. A. Pocklington (Callender's Bitumen, Telegraph and Waterproof Company), R. P. Wilson (Wilson and Clirehugh). It has been arranged to hold a second smoking concert on Monday, April 2nd.

The Telegraph and the Late Australian Banking Crisis.—Speaking at a meeting of the Bankers' Institute on Wednesday night, Mr. Nathaniel Cork, in the course of a Paper read by him on "The Late Australian Banking Crisis," said: "An essential element to reconstruction (of the banks) was rapidity. But for the cable these reconstructions would not have been possible. Every scheme, balance-sheet, and circular had to be cabled, with all the directions as to meetings. They were not mere ordinary balance-sheets which were thus wired, as the Official Receiver required an analysis of each item. These were the only documents the Courts had to guide them, and it was not unusual for £400 or £500 to be spent on a telegram. One large bank which closed on May 16th was thus enabled to re-open at both ends of the world with its numerous branches on June 19th—in the same time as the mail brought the news of the stoppage."

The Telegraphists' School of Science.—The seventeenth annual distribution of prizes and certificates gained by the students of the Telegraphists' School of Science took place on Tuesday afternoon in the Postmaster-General's deputation room. The chair was occupied by Mr. H. C. Fischer, who was supported by Mr. J. C. Lamb, C.M.G., Mr. J. Ardron, Mr. T. Barlow, Mr. J. Slingo, the principal, and several other officials. The report showed that the students of this school obtained as many successes in the telegraphy examination as all the other schools in the kingdom put together. The City and Guilds Technical Institute conduct this examination and offer two silver and three bronze medals, accompanied by valuable prizes, for the students throughout the kingdom. The two silver and one of the bronze medals were obtained by this school. The Chairman congratulated the meeting upon the success achieved, and pointed out that the work of the school contributed materially towards the present efficient and economical working of the Telegraph Department. The awards were then distributed by Mr. Lamb.

The Pacific Cable.—At the meeting of the Intercolonial Postal Conference, at Wellington, on Thursday last week, the debate was resumed on the motion submitted by Mr. J. G. Ward, the president, recommending the Governments of the various colonies to consider the desirability of entering into an agreement with the other countries concerned in the enterprise to guarantee the interest, at the rate of 4 per cent. per annum, on a capital of not more than £1,800,000, to any company undertaking to lay a Pacific cable, provided the tariff charge does not exceed 3s. per word for ordinary telegrams, 2s. per

Digitized by Google

word for Government telegrams, and 1s. 6d. per word for Press telegrams to and from Great Britain and the colonies. The motion was discussed at great length and eventually adopted. Mr. A. Wynne, the Postmaster-General of Victoria, declared during the deliberations that his colony was satisfied with the present cables; but that, if the whole of the colonies and the Imperial Government agreed to pay their proportion of the guarantee, he would support the scheme. Mr. W. H. Wilson, Postmaster-General of Queensland, announced that he was in thorough accord with the motion, and that the Government of Queensland would do everything in its power to help the promoters to carry the project to a successful issue. Dr. J. A. Cockburn, the representative of South Australia, and the Postmaster-General of Western Australia announced that they were unable to vote on the question.

English Anticipations.—The *Electrical World* of February 24th opens with the following paragraph, headed as above:—"In an otherwise able and interesting Paper, descriptive of the electrical industry in the United States, Mr. Preece, of London, makes the following remark in referring to the World's Fair: 'The American public were surprised to find how much we had anticipated their work.' We would be interested to know who those Americans were who expressed surprise at the supposed English anticipations, and also what those alleged anticipations were. We can think of only one, and that is the holding of exhibitions, as there were doubtless exhibitions in London before Columbus arrived here, and we do not think the American Indians held any. Probably Mr. Preece's sweeping statement was based on a passing flattering remark made by some Anglomaniac to tickle the vanity of an Englishman." How many smart comments a little attention to context would prevent. Detached from its surroundings the remark quoted certainly has a characteristically sweeping ring about it, but taken as a complete dose the paragraph, of which the sentence in question forms a part, is quite harmless, though it may, perhaps, be thought somewhat of an anti-climax. "The American public were surprised to find how much we in England had anticipated their work. Morse's first message, 'What has God wrought?' was sent only in 1844. Our history commenced in 1837. Our jubilee was celebrated in 1887. Theirs is to be celebrated this year."

The Physics of the Alternate-Current Arc.—In a recent number of *Electricité*, M. G. Claude gives an account of some experiments he has made on the alternating electric arc. In one of his experiments M. Claude joins two points, between which there is an alternating difference of potential of 2,400 volts (frequency about 80 per second), by about 12 incandescent lamps (16 c.p., 100 volt), a condenser of 0·1 microfarad capacity, and a make-and-break key all placed in series. When the key is closed, the circuit is traversed by the charge and discharge currents of the condenser, the magnitude of which can easily be calculated, and which suffice to make the filaments of the incandescent lamps just glow. If now the key is opened so that there exists a small spark-gap in the circuit (about 1mm.), an arc will be struck at this point. Now this arc is certainly an additional resistance in the circuit, small it may be, since it is formed between metal points, but which certainly cannot be less than that which existed when the metal points were in contact. It is now found that the lamps show an increased brilliancy, and this brilliancy increases as the arc is made longer. This increase is such that, for the longest arc obtainable (a little over 1mm.), the difference in potential between the terminals of each lamp rises from 30 volts to 90 volts, while the difference of potential between the terminals of the key is found to be about 1,200 volts. The author gives the following explanation of this experiment:—The arc is a discontinuous phenomenon, and requires a certain minimum value to start, and thus, while the electromotive force is below this value, no current passes, and the condenser remains uncharged. When the limiting electromotive force is reached the arc is struck, and the condenser is charged suddenly at a high potential. This charging of the condenser is limited to a fraction of the complete period, so that the charge current lasts a shorter time, and is of greater intensity than when no arc exists in the circuit. The absorption of energy in the lamps being proportional to the square of the current, is increased, for the mean square of the current in the circuit is increased when the arc is present. The material forming the points between which the arc is struck, exerts an important influence on the facility with which the arc is maintained when the difference of potential diminishes, so that, although a much longer arc can be obtained by using carbon terminals, the above effect is not nearly so well marked as with terminals of iron or copper. It is, of course, necessary to have a condenser placed in the circuit to obtain the increased brilliancy of the lamps, for otherwise during the time the spark is unable to pass no current passes, while when the current does pass it has the same value it would have at the same part of the cycle if the spark gap were closed. On performing the experiment M. Claude finds that when there is no condenser in circuit the luminosity of the lamps is slightly reduced when the arc is formed.

Brighton.—At a Local Government Board inquiry held last week, with reference to the proposal of the Town Council to borrow £32,500 for purposes of electric lighting, the counsel for the Corporation gave a succinct history of the Hammond undertaking, which the Corporation has agreed to purchase for £5,000. The Company, he said, not without reason, claimed to be the pioneer of electric lighting in Brighton. It was in 1882 that Mr. Hammond commenced to supply electricity, and in the following year his works were made over to the Hammond Electric Light and Power Supply Company. In that year (1883) the Corporation obtained their Order, but did not begin a supply for some years. In October, 1885, the Company became the Brighton Electric Lighting Company. In 1888 the Company became the Brighton and Hove Electric Light Company. The Company had lighted the borough without statutory authority by means of overhead wires. In June 1888, the Company gave notice of intention to apply for an Order. An inquiry was held, at which it was urged for the Company that they were the pioneers of the light in the borough, and that the Corporation were not supplying the inhabitants. Eventually the Board of Trade refused the Company's application. In June, 1889, the Company again gave notice of intention to apply again for an Order. The Council shortly afterwards resolved to establish electric lighting works, and in 1890 the second application of the Company was refused. In March, 1890, the Corporation resolved to extend their area of supply. In June, 1890, the Company gave notice of a third application for an Order. In March, 1891, negotiations were opened between the Company and the Corporation for the purchase of the Company's undertaking by the Corporation. In June, 1891, the Company gave notice of a fourth application for an Order. In November, 1891, negotiations for the purchase of the goodwill of the Company's undertaking were renewed, and a provisional agreement was drawn up; the consideration money therein was stated to be £7,000. The Lighting Committee recommended the acceptance of that contract, but the Town Council declined to adopt the recommendation. The result of that was that another (the fifth) application was made in June, 1892, for an Order. In November, also, they gave notice of their intention to introduce into Parliament a Bill to authorise them to supply electricity in the borough, and it became obvious that the Corporation would be put to very considerable expense again. On December 1, 1892, the second extension of the Corporation area of supply took place. A large part of the borough, however, was still not touched by the Corporation and was being supplied by the Company. In March, 1893, a Board of Trade inquiry was held in regard to the Company's fifth application, and the Board of Trade again refused its sanction, and in May the Company abandoned its Bill. The amounts and dates upon which the Corporation loans have been applied for in connection with electric lighting are as follows:—July, 1890, £32,500; April, 1892, £8,500; April, 1893, £30,000; and June, 1893, £12,531; and £2,700; making a total of £86,231. In October the Receiver for the debenture holders approached the Corporation, endeavouring to negotiate the sale of the goodwill of the Company, which was finally disposed of for £5,000. The present loan of £32,500 was for this purpose, and the extending of the Corporation's area of supply so as to include the whole of the borough.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Continued from page 410.*)

First Law of Thermodynamics.—Thermodynamics is the science of the relation between heat and mechanical energy. The simplest relation between these forms of energy is thus enunciated in the first law: Heat requires for its production, and produces by its disappearance, mechanical energy in the proportion of 772·55 foot-pounds for each British unit of heat. The idea which is fundamental to this law is that which is expressed by the doctrine of energy conservation; and the law by no means implies that from a single heat unit, derived from a hot body, it is possible to obtain 772·55 foot-pounds of useful work. For it is not possible.

Specific Heat of a Gas.—There are two quantities which represent the specific heat of a gas; according as the gas is heated at constant volume or at constant pressure. The former alone is the true specific heat, and represents the function of the heat which raises the temperature. The latter includes both the heat required to raise the temperature and that required to perform internal and external work in expanding the gas.

Elasticity of a Gas.—The elasticity of a gas is expressed as the ratio of any increment of the stress which limits its volume to the decrement of volume produced per unit of volume. If the decrease of volume takes place without any of the generated heat being allowed to pass from the mass of the gas, the elasticity is said to be adiabatic or isentropic. If the change of volume occurs under a condition of fixed temperature, the elasticity is called isothermal.

Adiabatic Elasticity.—During the adiabatic expansion or compression of a gas, the entropy of the gas is a constant quantity. Entropy is a thermodynamic function of great importance in the theory of heat engines; but we cannot discuss it fully in this short abstract. It may be defined as the ratio of the quantity of heat to the temperature, whenever a substance absorbs that quantity of heat from a hotter body under a condition of fixed temperature. In other words, the change of entropy during any isothermal change is equal to the ratio of the heat transference to the temperature at which it is transferred. In adiabatic compression the whole of the work done is stored as heat in the body; and during adiabatic expansion the whole of the work done is done by the intrinsic energy of the body.

Isothermal Elasticity.—During any isothermal change of state of a substance, heat will pass through the bounding walls in such amounts and in such a direction as will suffice to maintain a constant temperature in the substance. In a perfect gas the intrinsic energy of the substance is not altered by any isothermal change.

Cycle of Operations.—We now pass on to consider the relation between the heat supplied to a working substance and the mechanical work which that substance may perform in an engine. When a working substance changes its condition by virtue of some external action an *operation* is said to have been performed. When any series of operations results in the conditions of the working substance being in no respect different at the end of the series than they were at its commencement, then that series is called a *cycle of operations*. When the nature of the working substance and of the conditions under which it is worked are such that any given cycle of operations may be carried out in a stated order or in the reverse order, so that the cycle may be arrested at any point and carried on in the reverse direction for any portion of the complete cycle or for the whole of it, then that cycle is called a *reversible cycle* and the engine in which the working substance performs the cycle is called a *reversible engine*. A cycle which cannot be reversed is called an irreversible cycle; and any engine for which there is no reversible cycle is called an irreversible engine.

* Condensed from a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Efficiency of a Reversible Engine—It can easily be shown that a reversible engine has an efficiency which cannot be surpassed by any irreversible engine working under the same conditions of energy supply and exhaust. Every engine which is working as a mechanical motor is receiving energy from a source under definite conditions; and the surplus energy which it does not transform into mechanical energy of motion of machinery it rejects into the outlet or exhaust under definite and different conditions. Thus a water motor may take water at one level and reject it at a lower level; or a steam engine may take steam at one temperature and reject it at a lower temperature. Now, if there are two engines working between the same source and the same exhaust, the one of these being a reversible engine and the other not reversible, then the efficiency of the irreversible engine cannot possibly exceed, and will in practice be less than the efficiency of the reversible engine. For if not, we may employ the hypothetically more efficient irreversible engine to drive the reversible engine backwards, whereupon we should derive an amount of mechanical work, W, from an amount of energy, e, by the action of the irreversible engine, and should obtain from the same amount of mechanical work, W, expended on the reversible engine, an amount of energy, E, greater than e. This would result in the creation of $(E - e)$ units of energy. Consequently, we may say that the irreversible engine cannot derive from any given energy source and exhaust any higher efficiency than could be derived from that same set of conditions by a reversible engine.

Possible and Impossible Economies.—But the efficiency of a reversible engine is not necessarily 100 per cent., and it is very often necessarily very much below 100 per cent. It is the custom to call a reversible engine a *perfect* engine; but the phrase is only to be interpreted in the sense that such an engine perfectly utilises all the energy which is represented by the difference between the energy supplied and the energy sent into the exhaust. In a reversible engine all the energy is under perfect control, and the available portion of that energy is completely utilised for the purpose of the engine. The efficiency of a reversible engine under any given condition of working is, therefore, the *theoretical limit of efficiency* of all engines working under the same condition. Unless the conditions of the energy source and exhaust are altered, either separately or together, no engine can be improved so as to effect any economy beyond the economy represented by that of the reversible engine. Possible economies are those which are represented by the difference between the actual working efficiency of any engine and the theoretical limit determined by reversible conditions. Impossible economies are those which lie beyond the perfection of the reversible engine; but these are impossible only in respect to any given conditions of the source and exhaust, and become possible when it is possible to alter the conditions of the source and exhaust. In engines of some types, notably heat engines, it is theoretically impossible to alter the conditions of the exhaust beyond certain restricted limits; so that in these engines some economies are absolutely impossible.

Unimportance of the Working Substance.—In a reversible cycle the nature of the working substance has absolutely no importance in relation to the efficiency. For if it were possible to employ two reversible engines, having different efficiencies by virtue of their having different working substances, then we might place them both between the same energy source and exhaust; and we should, by causing the more efficient to run the less efficient in the reverse cycle, cause a continual creation of energy in the energy source.

The Limiting Efficiency of a Heat Engine.—It can be shown that the limiting efficiency of any heat engine, working between a temperature, θ_2, of the source and a temperature, θ_1, of the exhaust, cannot possibly exceed but will always be equal to

$$\eta = \frac{\theta_2 - \theta_1}{\theta_2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (67)$$

Consequently, the higher the temperature of the source, or the lower the temperature of the exhaust, the greater will be the

possible limit of efficiency of the engine. No known heat engine has a working efficiency as high as its highest possible limit, and for reasons which will afterwards be made clear.

Second Law of Thermodynamics.—At the same time the temperature of the exhaust cannot, advantageously, be lowered below the temperature of the coldest of the objects which surround the engine. This, the substance of the second law of thermodynamics, is usually expressed in the following terms: It is impossible, by means of inanimate material agency to derive mechanical effect from any portion of matter by cooling it below the temperature of the coldest of surrounding objects. Thus, if the coldest object near a heat engine is at 60°F. it will be no advantage to allow the working substance to become cooler than 60°F. in the engine. There is no such theoretical restriction of the temperature of the source, as to the point to which it may be raised. Practically, however, there *are* limits, for the operation of raising the temperature of the source may be costly, involving increased cost of plant and a higher rate of wear and tear, and possibly incidental losses of energy, which more than compensate the increased efficiency of the engine. Thus, by supplying a steam engine with steam at a higher temperature, we shall always raise the limiting thermodynamic efficiency of the engine, but the increased losses in the boiler and furnace, due to increased radiation, leakage, &c., may put a limit to the commercial value of the practice. In general, however, those types of heat engine which derive heat from a high temperature have greater possibilities of efficiency than those types which derive their heat from a lower temperature.

Thermodynamic Scale of Temperature.—If we consider equation (67) we see that the mechanical work which will be done by a quantity of heat, H, derived from any heat source at a temperature, θ_2, when working in a perfectly reversible engine, is proportional to the range in working temperature as measured by the expansibility of a perfect gas. If, therefore, the reversible engine could be worked without artificial cooling down to the temperature at which a perfect gas has no pressure nor volume, the whole of the heat, H, would be expended in mechanical work, and 100 per cent. efficiency would be attained. Moreover, equal amounts of work would be done during equal falls of temperature, throughout the entire range of the scale of temperatures. We are therefore led to see that the volumetric scale of temperatures given by a perfect gas is identical with a thermodynamic scale of temperatures, in which equal degrees of temperature represent equal amounts of work done in a reversible engine. Now, it has been shown by Joule and others that air, at ordinary temperatures, expands without doing internal work; or, in other words, that air in this condition behaves sensibly as a perfect gas. Consequently, the scale of temperatures as fixed by equal amounts of expansion of air in an air thermometer, within ordinary ranges of temperature, is identical with the absolute thermodynamic scale of temperatures; and the absolute zeros of these two scales are sensibly the same. Now, the absolute zero of heat of a reversible heat engine is independent of the nature of the working substance. Therefore the absolute zero of temperature is identical for all substances, and is identical with the temperature of zero volume as fixed by the perfect gas or air thermometer. Its value is, approximately, -460°F.

Availability and Heat Transference.—As a consequence of the foregoing thermodynamic considerations, we see that although the mechanical equivalent of a given amount of heat, H, is a fixed and unalterable quantity, yet the amount of mechanical work which that heat will do when supplied to a heat-engine is by no means so unalterable. For example, assuming the lowest working temperature to be $60+460$ absolute degrees Fah., let us suppose that we have a working substance into which we put 100 units of heat, and thereby raise its temperature to just twice its former absolute value, namely to $580+460$ absolute degrees Fah. Then, we may possibly obtain an efficiency of 50 per cent. in the heat-engine, utilising 50 of the heat units, and necessarily wasting the other 50 heat units. But, if we had supplied the 100 heat units to, say, twice as much working substance, we should evidently not have raised this substance to so high a temperature. Let us suppose that we should thereby have raised it to $320+460$ absolute degrees Fah., then the possible efficiency would be only 33·3 per cent.; so that 66·6 heat units will now be wasted, instead of only 50 as in the former case. We may advantageously carry the idea a little further. Let us suppose that the 100 units of heat were originally supplied to a small quantity of working substance, so that a very high temperature was produced; but that, in some way or other, the heat suddenly became distributed over a greater amount of working substance, through the contact of the hot body with a large mass of much colder working material. No heat would necessarily be lost by the mere re-distribution of the heat throughout a larger mass, so that there would still be the 100 units in the working substance. But owing to the fall in temperature which would abruptly occur, on account of the contact of the colder mass, the availability of the 100 units would become seriously impaired. For example, we may have 100 heat units in a furnace at a very high temperature indeed, and, as a consequence, we may have a high degree of availability. But if we pass the whole of the 100 units of heat through a boiler plate into a mass of relatively cold water, and spread the heat over a large mass of water at a lower temperature than that of the furnace, we shall find that a much lower figure will represent the availability of those 100 units for useful mechanical work. Wherever, then, a heated working substance becomes cooled by the transference of the whole or a portion of its heat to a relatively colder portion of working substance, a sudden and irrecoverable fall in the availability of the heat will take place. Consequently, wherever, in a heat engine, the heat is made to pass from a hotter to a colder body, this degradation of the availability of the heat will occur. It is the *bête noir* of every heat engine.

(*To be continued.*)

THE SCARBOROUGH ELECTRIC SUPPLY STATION.

In the year 1891 the Corporation of Scarborough obtained a Provisional Order, enabling them to supply electricity throughout the borough. The Corporation, however, ultimately determined to transfer to other parties their powers and duties under this order. The Scarborough Electric Supply Company was consequently formed. The terms of agreement comprise power for the Corporation to purchase the undertaking at the end of 21 years, 32 years, or any subsequently completed period of five years. If the Corporation exercise their option of purchase at the end of 21 years, they are to pay the value of the undertaking as a current going concern. If the option be exercised by them at the expiration of 32 years, or any later period, they are to pay for the undertaking according to the terms specified in the Electric Lighting Acts at the end of 42 years. It is further agreed that the maximum price of electricity for private consumers be 7d. per Board of Trade unit, and for street lighting 6d. per unit. The price is to be reduced according to a specified sliding-scale, which, however, does not come into effect until a cumulative dividend, at the rate of 8 per cent. per annum, has been paid to the shareholders.

The Company having been formed with a nominal capital of £50,000, of which £24,200 is now subscribed, a site for the generating station in the western outskirts of the borough, within about 100 yards of a railway-siding for coal, was purchased.

The ground comprises about two acres, about one half of which has been converted into a condensing pond. The existing buildings cover a space of a little over 60ft. by 70ft., so that there is ample room for all the extensions that are likely to be required for many years to come. The condensing pond is about one acre in extent, with an average depth, when full, of about 4ft., and is calculated to be of sufficient size for condensing all the steam required for supplying 50,000 8-c.p. lamps. The chimney is 130ft. in height, and being 7ft. internal diameter at the base, is calculated to be of sufficient size for extensions of the plant up to 1,000 kilowatts. The engine-room is a handsome and lofty apartment, 60ft. by 34ft.,

Digitized by Google

lined with glazed bricks, with a travelling-crane running over its entire length. It is shown in elevation in Fig. 1, and in plan in Fig. 2.

The generating plant, the whole of which has been supplied by Messrs. C. A. Parsons and Co., Newcastle-on-Tyne, at present consist of two Parsons condensing steam turbine alternators, each capable of an output of 150 kilowatts. Each engine is entirely independent of the other, and consists of a compound steam turbine, arranged for expansion from the 130lb. per square inch boiler pressure, down to a condenser pressure of ½lb. absolute, or a range of about 250-fold expansion. The turbine revolves at 4,800 revolutions per minute, and is coupled direct to a two-pole alternator, giving 75 amperes at 2,000 volts, with a periodicity of 80 complete alternations per second. To the same spindle is coupled the exciter. The whole is entirely self-contained, and stands in a galvanised iron drip-pan on rubber blocks, without any holding-down bolts. An automatic variable cut-off valve gear and governor, electrically controlled, maintains a constant pressure on the terminals, and enables the full range of expansion to be maintained at light loads, thus securing good economy of fuel on the all-day load. One of the two machines actually at Scarborough was tested as to steam consumption in March last by Prof. Alex. B. W. Kennedy, and from the diagram that accompanies his report it appears that while the steam consumed at full load was slightly less than 20lb. per e.h.p., at ¾ load it was only 21lb., at ½ load 23lb., and at ¼ load 29lb. per e.h.p.*

The turbine alternators stand upon a solid bed consisting of stone walls filled in with rubble and cemented over the top, which runs the whole length of the engine room, occupying a middle position between the two side walls. As already mentioned, there are at present only two machines, but the engine room itself and the bed have been constructed of sufficient size for five additional machines. There is ample room for these to be of larger size than the present 150 kilowatt type, so that there is space in the engine room for plant to the total output of 1,500 kilowatts, or, say, 2,000 e.h.p., without overcrowding.

The steam condensers are of the jet description, but differ somewhat from the usual type. A separate water pump is placed below the condenser, no injection water proper being admitted to the air pump, which is placed above. By this arrangement it is sought to produce a better vacuum than is usual with jet condensers, and at the same time the power required to work the pumps is considerably reduced. The condenser pumps, of which there are at present two, one for each turbine alternator, are contained in separate wells sunk in the ground, and are worked from the crossheads of two small tandem compound auxiliary vertical engines with cylinders 4½in. and 7in. diameter, and 8in. stroke, supported on girders so as to stand in the engine room above.

The main steam pipes, which are of cast iron with bends and closing length of solid drawn copper, are arranged on the ring system, and are fitted with valves, so that any section can be shut off for repairs without interfering with the running of the plant. It is difficult to see why so brittle and unreliable a material as cast-iron was selected for the steam pipes. Strength can, of course, to a certain extent be obtained by casting thick pipes with very great care; but the unreliability of the material is increased rather than decreased by a greater thickness of casting. The engine-room floor being raised there is a passage way underneath it on each side of the engine bed, and all pipes are taken along this passage with the advantage of keeping the engine room cool. Two Worthington pumps with case-hardened valve gear and gun metal water bodies supply feed water to the boilers, and the exhaust from these pumps is utilised in a Berryman feed water heater for heating the feed water before it passes to the boilers. The exhaust steam from the condenser engines can be similarly utilised or can be turned into the condensers at will. The exhaust pipes from the turbine alternators are also so arranged that either turbine can be worked with either condenser, or can exhaust into the atmosphere. The water for condensing as well as the feed water is drawn from the cooling pond already alluded to.

The first bay of the boiler house, at present erected, is designed to contain three Lancashire boilers. Only two have, however, so far, been put in place, and are each 28ft. long by 7ft. 6in. diameter. They have flues 3ft. in diameter and are fitted with three cross tubes in each flue. The working pressure is 140lb. per square inch. When additional boilers are required it is intended to add further bays to the boiler house. Behind the existing boilers is placed a Sykes superheater for superheating the steam on its way to the turbines. The superheater is placed in the main flue with by-pass dampers, so that it can be put out of use when required, and with additional dampers for allowing the direct flame from the internal flues of the boilers to reach the superheater immediately, instead of after traversing the side boiler flues, this arrangement being found advantageous when working at light loads. The use of superheated steam produced in this manner is found to

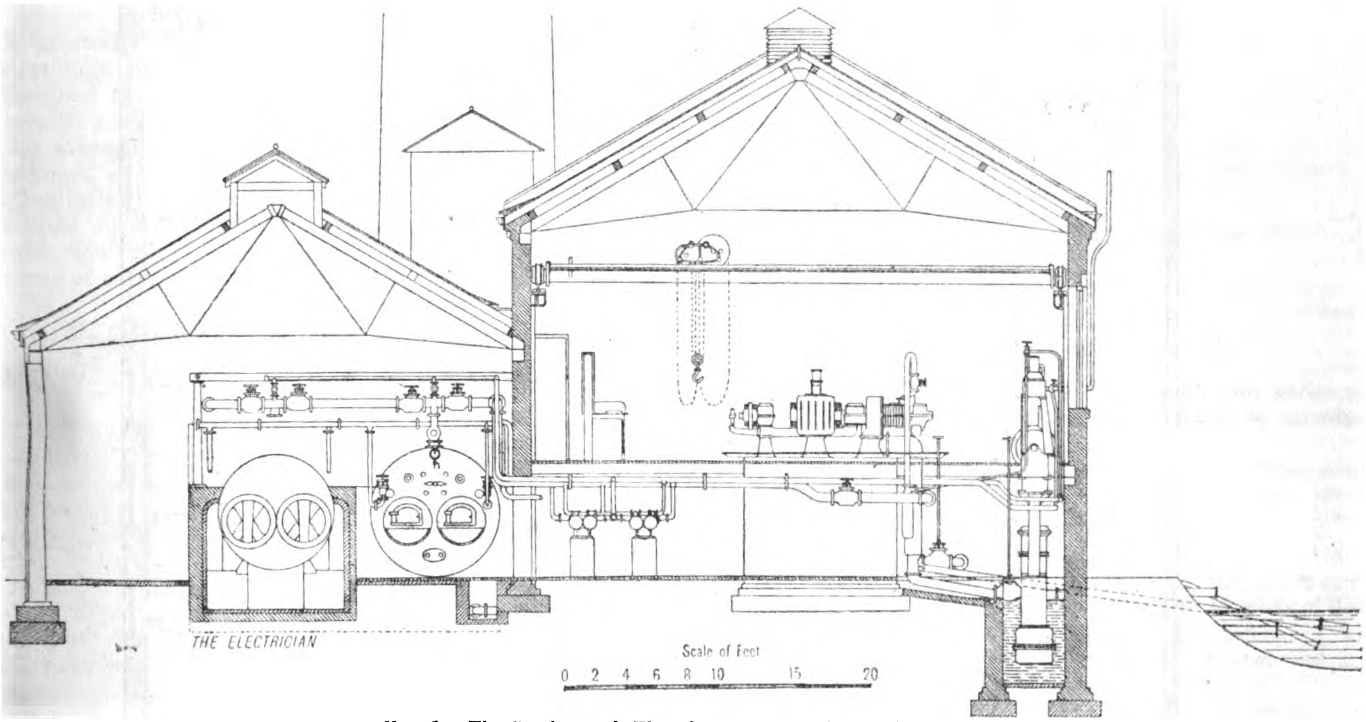

Fig. 1.—The Scarborough Electric Supply Station.—Elevation.

* See *The Electrician*, Vol. XXXI., pp. 303 and 315. *See also* Vol. XXX., pp. 25 and 34.

improve the economy of the turbines by about 10 per cent., and as in the Parsons turbines there is no internal lubrication or any packings to be burnt, the superheated steam has no deteriorating effect.

Along the entire side of the engine room opposite to the condenser engines, the switch board is arranged. Parallel running is not attempted, the exceptionally light load running of the turbine alternators rendering it of small value. The switch board is at present arranged for three alternators and four supply circuits, but is capable of being extended without alteration for dealing with seven alternators and twelve circuits. Each alternator has its own voltmeter, and each alternator and chief business quarters of the town the transformers are placed in sub-stations, consisting of cast iron boxes, with water-tight covers similar to the junction boxes, sunk beneath the foot pavement, as shown in Fig. 4. Each of these sub-stations is of sufficient to size contain a 50-h.p. transformer, but at present in most cases smaller transformers are in use.

The sub-station boxes are connected by two lines of cast-iron pipes, one being for the high-pressure and the other for the 100-volt low-pressure cables, and recesses in the sides of the sub-station boxes contain, in compartments with separate water-tight covers, the high and low-pressure fuses connected with each transformer.

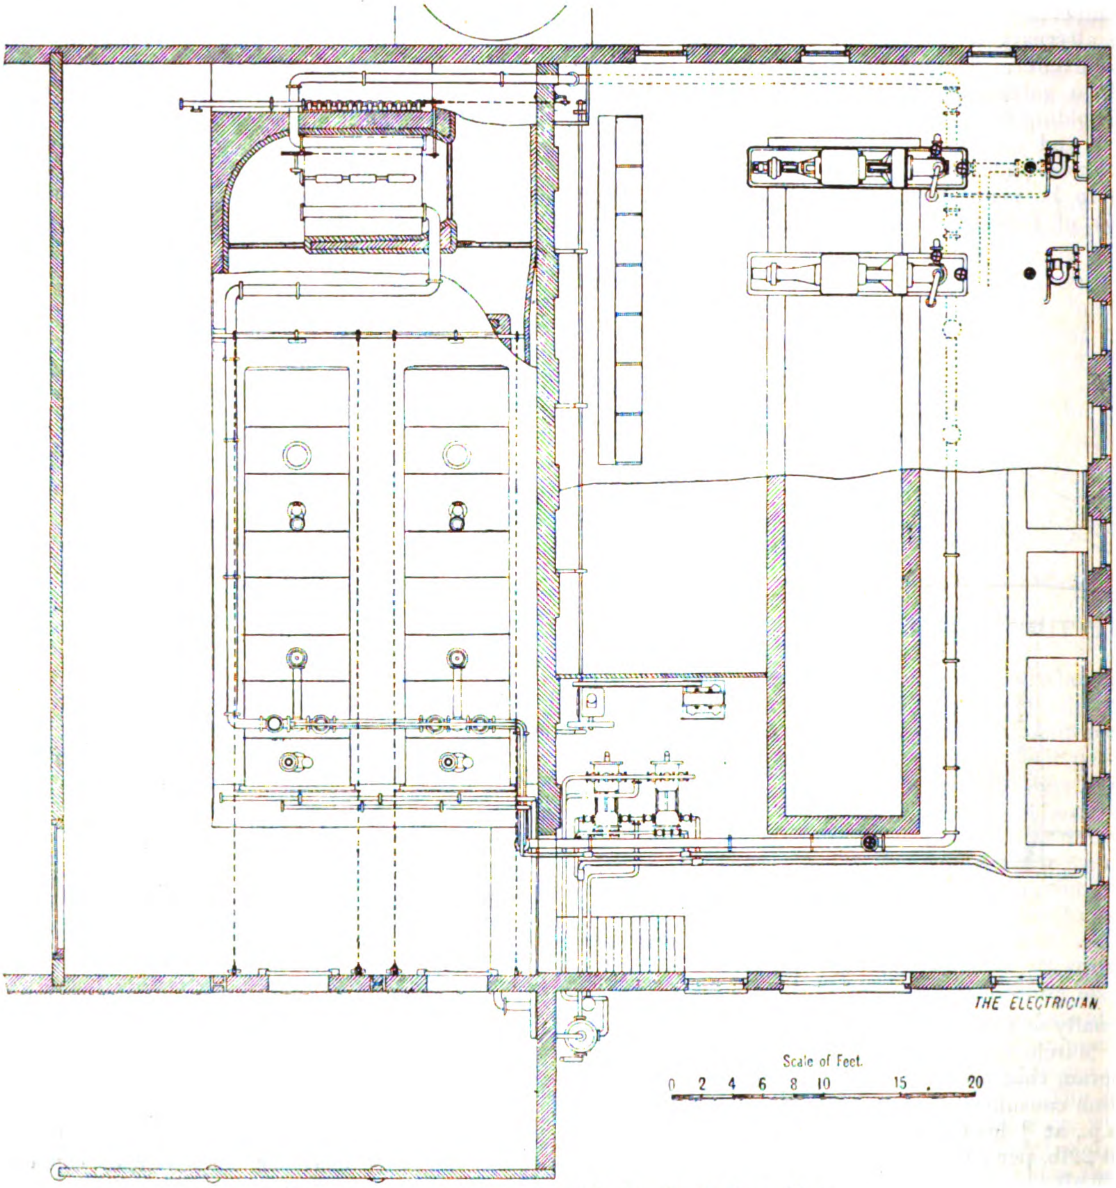

Fig. 2.—The Scarborough Electric Supply Station.—Plan.

each circuit its own ammeter. In addition, in circuit with each alternator is a recording Thomson wattmeter that measures the output in Board of Trade units. The switches are of the snap-over type, and so arranged that by their means any circuit can be thrown instantaneously from one alternator on to another without any cessation of the light.

The system of mains laid throughout the town consists of indiarubber covered cables drawn into cast iron pipes. The pipes near the station are 6in. internal diameter, in other portions of the town they are 4in. and 3in. diameter. The junction boxes are entirely of cast iron, the lids being screwed down and rendered water and air tight by means of indiarubber rings. A sectional elevation of a junction box is shown in Fig. 3. Connection to consumers is made by means of indiarubber-covered cables led through wrought iron pipes, the ends of which are screwed into the junction boxes. In the

All joints in the cast-iron pipes are run in with lead, and thus the whole system of pipes and boxes is made metallically continuous and water-tight. In order to keep the whole dry and free from gas, and also in order to provide against the mildew that is apt to attack the braiding of cables in confined and unventilated places, air is pumped into the pipes at the supply station at a pressure of about 2in. of water, by means of a small Root's blower worked by a small auxiliary steam engine, which also supplies power to work the automatic scrapers of the superheater. The Root's blower draws its air from outside the engine house, the air on its way to the blower being deprived of its natural moisture by being caused to pass backwards and forwards over a number of trays supplied with chloride of calcium. The air is allowed to escape at the extreme ends of the system of pipes, and thus a continuous forced ventilation of dry air is ensured.

Digitized by Google

The cables, which are of Silvertown manufacture, are insulated with vulcanised indiarubber, all the joints being vulcanised *in situ*. The high-pressure cables, which are mostly 7/16, are rated at 6,000 megohms per mile, the low-pressure cables being rated at 600 megohms per mile. All cables are specially extra-taped overall, in addition to being braided. Fowler-Waring concentric armoured cable is used for conveying high-pressure current to one consumer, whose house is in an isolated position at some distance from the town. As already mentioned, there are low-pressure mains fed from street transformers in the part of the town where the density of lighting

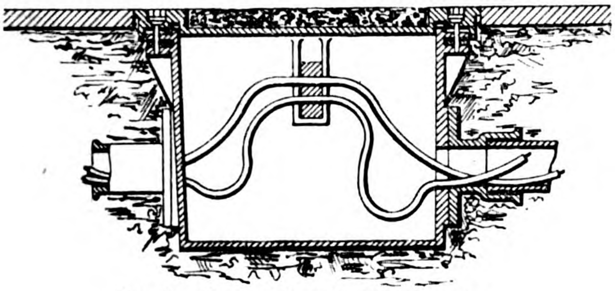

Fig. 3.—Section through Junction Box.

is greatest. Elsewhere the transformers are placed on the consumers' premises. The transformers have been specially designed to give a high all-day efficiency. The larger sizes give 90 per cent. efficiency at one-tenth load, which is about the average load on transformers in such a town as Scarborough, and even such a small size as a 4-h.p. transformer gives at low loads a very fair efficiency. This has been accomplished by reducing the all-day loss in the iron due to hysteresis and eddy currents to a minimum. The efficiency curve of one of the transformers is shown in Fig. 5. The small

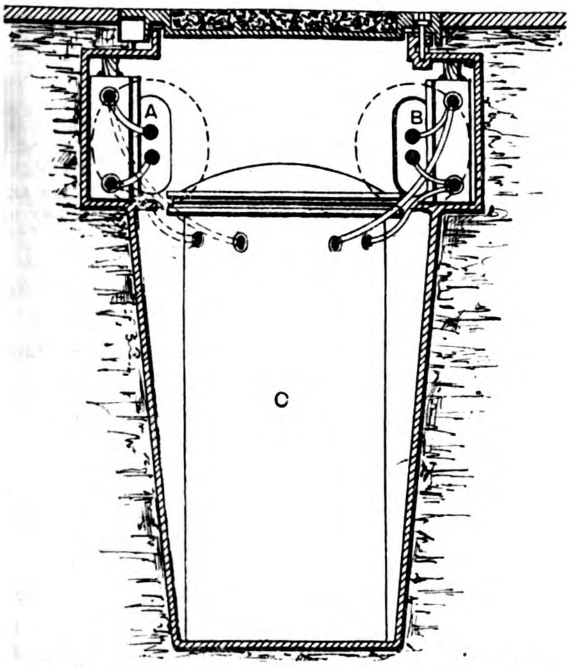

Fig. 4.—Section through Sub-station. A, High Pressure Mains and Fuses ; B, Low Pressure Mains and Fuses ; C, Transformer.

sizes are put in round cast-iron water-tight cases which are impervious to damp, the larger ones in square cases filled with oil. Before leaving the makers' works the transformers were all tested with an alternating pressure of 4,000 volts, or double the working pressure, for a considerable time. Each transformer is fitted with a Cardew earthing device. The consumers' meters are all of the Schallenberger type.

Altogether some $5\frac{1}{2}$ miles of cast-iron pipes have been laid for mains, containing about 18 miles of cable. At present 66 separate consumers are being supplied, and there are 12 substations and 38 transformers upon consumers' premises. The capital expenditure has been approximately as follows :—

Land for site of generating station and condensing pond...	£1,625
Buildings, chimney, and making of pond	3,341
Machinery (including boilers), engines, alternators, condensers, and equipment of station	7,934
Mains, including pipes, junction and sub-station boxes, cables and laying	5,445
Transformers, meters, electrical instruments, tools, and sundries	1,595
	£19,940

Regular working of the plant was commenced last September, and since December the supply has been continuous night and day. On September 1, 1893, the equivalent of only 468 8-c.p. lamps were connected to the mains, but by December 31st this number had increased to 4,114, by February, 1894, to 4,489, and by the end of March it is anticipated that nearly 6,000 lamps will be connected.

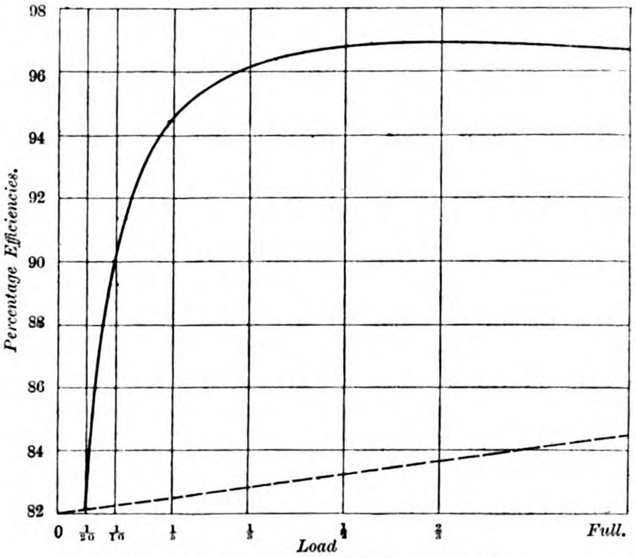

Fig. 5.—Transformer Efficiency Curve.

The Company's charge per Board of Trade unit varies with the number of units consumed in each quarter, in accordance with the following scale :—

Number of units consumed per quarter.	Price per unit.
Not exceeding 200 units.....	$6\frac{1}{2}$d.
Exceeding 200 and not exceeding 400 units	$6\frac{1}{4}$d.
Exceeding 400 and not exceeding 800 units.....................	6d.
Exceeding 800 units......	$5\frac{3}{4}$d.

Five per cent. discount is allowed for cash, and meter rent is charged at the rate of 2s. per quarter for any number of lights not exceeding the equivalent of 50 8-c.p. 35-watt lamps, with 6d. extra per quarter for every additional 25 such lamps or their equivalent connected.

The laying of the mains, &c., has been carried out under the superintendence of Mr. G. S. Peck, the resident engineer. Mr. Bernard Drake, the Corporation consulting engineer, has watched the interests of the Corporation. Mr. A. A. C. Swinton has throughout acted as consulting engineer and managing director for the Company.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, March 16th.

Institution of Electrical Engineers.

8 p.m. Students' Meeting at 28, Victoria-street. The following Paper will be read : "The Construction of Resistances," by D. K. Morris.

Royal Institution.

9 p.m. Evening Discourse: "The Scientific Work of Tyndall," by the Rt. Hon. Lord Rayleigh, F.R.S.

SATURDAY, March 17th.

Royal Institution.

3 p.m. Afternoon Lecture on "Light," with special reference to the Optical Discoveries of Newton, by the Rt. Hon. Lord Rayleigh, F.R.S.

TUESDAY, March 20th.

Institution of Civil Engineers.

8 p.m. Ordinary Meeting. The following Paper will be discussed : "The Prevention and Detection of Waste of Water," by Ernest Collins, M.Inst.C.E.

WEDNESDAY, March 21st.

Royal Meteorological Society.

8 p.m. Ordinary Meeting at 25, Great George-st.

NOW READY.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK FOR 1894.

(THE BIG BLUE BOOK.)

1,000 pages of valuable information; 550 closely-printed pages of Directory matter.

Price 7/6, post free 8/3; abroad 8/10.

GOOD-FRIDAY WEEK.

"THE ELECTRICIAN" will be published on THURSDAY in Good Friday week instead of on Friday. Communications intended for this issue must reach us not later than Wednesday Morning's post.

Alterations to existing Advertisements and copy for new Advertisements should reach the Publisher on Tuesday, but in any case not later than Wednesday mid-day.

ANONYMOUS JOURNALISM.

The practice of anonymity in journalism, is, we fancy, too deeply rooted, and its advantages too generally acknowledged for anything that may be said in disfavour of it to shake its established reputation, or to curtail its recognised power. That it is a power we readily admit; and Mr. WALKER, who writes on the subject in these pages to-day, will no doubt regard the admission as conceding the point which he raises, namely, that anonymity gives a fictitious or meretricious influence to unsigned writing. But he is mistaken, to begin with, in supposing that modern journalism derives its strength from anonymity. Does a novel fare any better for being published anonymously? Is a philosophical treatise or a theological disquisition more respectfully received when the author remains concealed? If the book is a good book the author's modesty commands public respect; and to that extent so, too, does the anonymity of individual journalists whose writings are of commanding excellence. The writer who wishes to face the public, standing in his own boots, seeks entrance into the magazines where signed articles are the rule. If, on the other hand, he enjoys the distinction of contributing, for example, to the *Quarterly Review*, he has to sink his individuality and, as Mr. WALKER would call it, hide himself behind a veil. The explanation is much simpler; and the result tells all against

Digitized by Google

Mr. WALKER's theory. The one set of articles are a miscellaneous collection of isolated and often conflicting ideas; the other is a combination of intellectual forces directed towards a given object, or at all events consistently moving on one line. Mr. WALKER's assertion that a signed leader or leaderette would be as influential, or even more so, if it bore the author's name can only be sustained by asserting it of the older Reviews as compared with the modern Magazines; which would be absurd.

So much for what we deem to be Mr. WALKER's initial error. That we do honour to his good intentions will be evident from our giving them the publicity they deserve: but that we dissent from his conclusions is equally plain by the anonymous comments we are now making upon them. Here we can picture our esteemed correspondent—and not only him but many another reader who vaguely suspects the secret iniquities of anonymous journalism—exclaiming, "Why don't you put your name to it?" When the Governor of Tilbury Fort town proffered QUEEN ELIZABETH fifteen reasons for not firing a salute, and began with, "Your Majesty, we had no powder," the QUEEN cut him short with, "That's enough." We could give more than fifteen reasons for not putting a name to this or any other editorial matter in these pages. One will suffice: We have no name. The pen writes, and Mr. WALKER may identify the style of the nib if he think it worth while; but several hands direct it, to say nothing of heads. And this is at once the obligation and strength of anonymity in journalism. The picture of it as a coterie of individual items, each pursuing his own pet hobby, each indulging his own personal spite, each assuming the airs of an infallible judge, is wholly false to the reality. Some journals are, we understand, conducted on those lines, but they do not, and cannot, command any influence of the kind Mr. WALKER deprecates. If his contention is that the united and well-digested opinions of an editorial staff, put into readable shape by a competent writer, ought to carry no more weight than if it were the work of the printer's devil who takes it up to the compositors, it would ill become us to contradict him. All the same, it *does* carry more weight; and herein lies the reason and the justification for the editorial "we." It is not an individual, but a collective expression. One man, it is true, often writes an article from first word to last, with his own pen, and be he editor or no, not a single alteration may be made by another hand. None the less, if he understand his business, he sinks his personality, and the very use of this editorial "we" is valuable as a continual reminder to the writer that his private sentiments and opinions, his likes and dislikes, must be suppressed, and that the work in hand, be it only a five-line review of an insignificant *brochure*, is invested with a peculiar responsibility.

If we may do so without offence, we should like to illustrate our point from Mr. WALKER's own case. Very properly he writes under his own name. But the opinions to which he gives such strong expression would, we venture to suggest, have been far more effective without his signature; for it would then have been evident that the whole weight of editorial opinion was of his way of thinking. Of course, it would not be then identified with the real author's name; but this is where journalistic modesty comes in; journalism is bent on enlightening public opinion, and attains its end with a lamp of many candle-power rather than by a succession of penny dips. Not that we would class the enemies of anonymous journalism in this latter category; all that we mean is that they will make a greater shine when they have persuaded a number of other lights to cluster round them, and merged their personal identity in the object common to them all.

As to the general and too sweeping imputations contained in Mr. WALKER's article, we have little to say; for our conscience does not trouble us in respect of any of the counts in the indictment which he is at such pains to draw up. Anonymous letters very rarely appear in our columns, and when they do the reason is generally to be found in the contents, as for example in the grumblings which we have recently published about the remuneration of the subordinate members of the staff of supply companies. With regard to reviews of books, we occupy the somewhat unusual position of frequently adding the reviewer's name or initials when the work reviewed is an important one, our intention being, partly at least, to disclaim anonymity where the editorial functions, as such, have had no hand. For the minor reviews, requiring no assistance from an expert, they are subject to editorial censorship; and we are inclined to believe that elsewhere, as well as in this journal, there is no room for the personal bias on which Mr. WALKER so bitterly animadverts. Similarly, there is no room for the "tyro" whom he pictures as writing for technical journals under the cloak of anonymity. It is true that the professional journalist may remain unnamed to the end of his days; but to argue from this that he gets into the charmed circle on the easy terms, as Mr. WALKER seems to imagine, of not putting his name to what he writes, is at once a libel on the writer and an affront to the reader. Journalism, whether technical or political, cannot subsist on the work of amateurs, whose writing has "no face value;" and when a face value is there the owner's name would either give it a fictitious advantage or reduce it below its actual merits. If you want face value, surely you are more likely to get it by letting the face alone speak for itself. So, at least, thinks *The Electrician.*

ANONYMITY IN TECHNICAL JOURNALISM.

BY SYDNEY F. WALKER.

A French novelist has recently raised the question whether all articles, even in papers devoted to politics, should not be signed, as they are in France; and readers of technical literature can hardly help asking themselves whether it would be better for the advancement of science, and of engineering, if all articles and letters that appear in technical journals were signed with the true names of the writers. In the present writer's opinion it would, and for the following reasons:—

In the first place, he would ask: "What good reason can be given for concealing the name of the writer?"

If a man, or woman, has a message to deliver, as he or she presumably has if they write, should they not deliver it in the face of the world, not from behind a door?

If a man goes forth as a preacher, as a missionary, for no matter what cause, he does not preach from behind a screen, but from where all his hearers can see him. Often a preacher's own individuality does much to enforce the lesson he wishes to teach. And is not this equally true of science or engineering? If a professor lectures to an audience, whether it be upon some recent discovery, some old truth that is new to his present hearers, or on some point upon which he holds views at variance with previously accepted teachings, does he lecture from where he cannot be seen? Would it not be absurd for him to do so? Why, then, when his lecture is a written one, should his name be concealed? And does not the concealment take from the force of his message, just as a screen would if his lecture were delivered orally.

It may be said that a young writer would not be as well received if his name were disclosed as if he wrote anonymously, and, therefore, he should be allowed to write without signature. A little consideration will show that there is not much in this argument. A man's writings are read, in technical literature at least, for one of two reasons. Either because he is known to have something to say, the fruit of thought or experience, or because what he writes carries its face value.

Digitized by Google

Now, if the writings of a tyro have no face value, surely there is no reason for him to write, nor any reason for concealing his identity. On the other hand, if what he writes commands attention, surely it would be best for him and for his readers that his name should appear.

Of course, where the concealment is transparent—as, say, when everyone knows that a certain man edits a certain paper, and writes a certain portion of that paper, the matter of his signature is almost one of indifference, but not always. Editors sometimes delegate their work to subordinates. They say, very properly, that they assume the responsibility of what is written for them, but unfortunately they cannot clothe the subordinate with their own style and their own thought and experience, so that the result is, an article or a leaderette given to readers as their own, which is not their own in any sense. Why not sign a leader or leaderette? Up again, it will be acknowledged, the writer presumes, that men do their best work over their own names. No man is so careful of his work when he believes that no one will know who has done it as he is when his name is attached to the work.

Taking the case of reviews of books also. If a review does its duty, it judges the book under review from the reader's standpoint. A reader is *supposed* to be, and would be, guided in the purchase of the book, if he had confidence in the review. The paper, in fact, appoints a judge for its readers, very much as an agricultural association appoints judges for its members and the visitors to its show.

This book, says the judge appointed by the paper, is well or badly written, is correct or the reverse, just as the judge appointed at a show may say, this fowl or this rose is well or badly formed, is of true breed or true type or not. Would it not be absurd for the committee of the agricultural or flower show to conceal the identity of their judges? Is it not equally absurd and equally destructive of confidence, to conceal the identity of the judge appointed to review a book?

It may be said that reviewers do their duty, and are more independent when they write anonymously. Unfortunately they do not always. In too many instances unsigned reviews of books consist merely of an extract from the preface, with a few remarks added. In too many others the anonymity of the reviewer is made the cover for a direct personal attack upon the author of the book, an attack that would not have been made if the reviewer had been obliged to sign his review. And this brings us to the real reason why many writers, especially those who write upon electrical subjects, prefer concealing their names, viz., that they may indulge in personalities and make unfounded assertions unchecked. Up there it is so easy to sit upon a high perch and call out sounding phrases when no one can see you. The writer who indulges in personalities does not add to the knowledge possessed by the world, nor bring a thought worth dwelling on, to the discussion of any problem, any more than a feathered parrot does. Like "Pretty Polly," he is amused at the sound of his own voice, at the annoyance he sometimes causes; and, like his feathered prototype, he is sublimely unconscious that he is degrading the God-like faculty of speech, or the noble art of writing. "Pretty Polly," of course, can hardly be expected to understand that time occupied in personalities is time wasted, doubly wasted. The time employed in writing an irrelevant attack would have been better employed in producing sound criticism, or original thought. The time employed in replying to the attack, if reply is made, is equally wasted.

Electrical engineers in particular should avoid anonymity. Even in the arena, when they stand face to face they are often unable to resist the temptation to give each other *one*. Is it not delightfully feminine? How much more, then, must they be tempted to do so when they are able to stab their adversary, even their friend, if a rival, and escape unseen.

An incidental result of writing letters over *noms de plume*—a practice the present writer is pleased to observe is dying out—is the absurdity presented when two writers holding diametrically opposite views adopt the same *nom de plume*, a by no means unusual occurrence.

The writer of this article trusts that his readers will think carefully over what he has written above. His object in writing as he has done is to raise the tone and status of electrical engineers, and particularly of writers upon electrical subjects.

NOTES ON DESIGNING A SYSTEM OF UNDERGROUND ELECTRIC LIGHT MAINS.*

BY JOHN H. RIDER.

The importance of a satisfactory system of underground mains in a scheme for town lighting may be estimated, when we consider that in generating the electricity we have only done half the work. We have still to convey it to the consumers, and in many cases this means to distribute it over a wide area. At whatever pressure we may generate, we are compelled by law to deliver to our customers at a low pressure. In the case of a general low-pressure system, this is done by means of a distributing network, fed at various points by feeder cables. When the generation is at high pressure we may use either a low-pressure distributing network, fed through transformers at various points, or we may place transformers on the consumer' premises, and so have practically no low-pressure network at all. The Board of Trade, however, will now only give its sanction for this latter course on the distinct understanding that when called upon to do so by them a low pressure distributing main will be laid down, and the house transformers removed. Therefore all arrangements using house-transformers can only be looked upon as of a temporary nature.

At the outset we should make a radical distinction between "distributing mains" and "feeders." Distributing mains are those from which the services to the houses are taken. It is therefore necessary to have them of such a cross-section that the fall in pressure from any feeding point to the farthest service on that section does not exceed, say, 2 per cent. when all the lamps are burning. In the case of an ordinary business street it will be found necessary to have the feeding points at not greater than about 250 yards apart in order to have the distributing mains of a reasonable size.

"Feeders" are mains going direct from the station to the various feeding points, and their use is to feed the distributing network through transformers or otherwise. While we may take more than one feeder to any feeding centre, yet in no case should we arrange any one feeder to supply more than one feeding centre. We should find it impossible to keep the voltage constant all over our distributing network if we did so. The pressure at the feeding centres must be kept constant by raising the pressure of the several feeders at the station, in proportion to the current flowing through them. As it is impossible to say that the demand for current will always be equal all over the network, it will be necessary to regulate each feeder independently of the others. On direct-current systems this means raising the pressure of the dynamos when the load comes on, and, when the feeders are supplied from omnibus bars, having a regulating resistance in each feeder. On alternating current systems the pressure of the machines need not be altered, as the necessary voltage may be added to the feeders by means of adjustable transformers in series with them.

The most satisfactory method of indicating at the station the voltage at the different feeding centres is to run back pilot wires from each, and to connect them to voltmeters on the switchboard. The attendant has then simply to regulate for constant volts, and the current in each feeder will take care of itself. In all cases the pilot wires should be connected to the low-pressure network, and not to the high-pressure side of the transformers, as has been done in some alternating current stations.

We may divide the many systems of laying mains into two chief classes, "drawn in" and "built in." By the former I mean those which are drawn into pipes or conduits, and by the latter those which are either laid direct in the ground, such as armoured cables, or run in solid with bitumen, &c., such as Callender's solid system. For low-pressure distributing mains the disadvantage of the "built-in" system of being unable to increase without reopening the streets need not be one at all, for if these mains be calculated with reasonable care for the requirements of the district they should rarely require enlarging. And if at some future time a greater demand comes at one point than the cables can carry, the simplest way is to run another feeder to that point, and to leave the low-pressure network as it was. This, of course, means that the feeders should be laid on a "drawn-in" system.

I venture to think that a combined system of "drawn in" for the feeders, and "built in" for the distributing mains, offers a number of advantages. The distributing mains should only require extending in order to light new streets, and opening the ground may be therefore allowed. But new feeders have in many cases to be taken through streets already lighted in order to reach the new districts, and so they should be "drawn in" to avoid opening the same streets a second time. Opening the streets is such a nuisance to everybody, besides being very expensive, that this point is well worth consideration.

Judging from recent experiences, a considerable difficulty in connection with a "drawn-in" system is the danger from gas

* Abstract of a Paper read before the Northern Society of Electrical Engineers, March 12, 1894.

Digitized by Google

explosions. There can be little doubt that the gas comes from leaky or broken gas pipes in the vicinity of the conduit. It is useless to look to the gas companies to lay their mains so that leakage would become impossible. An unlooked-for subsidence of the soil may cause a drawn joint or a broken pipe, and it then only requires a spark to complete the mischief. A thorough ventilation of all electric pipes, conduits, and manholes, together with great care in the laying and subsequent inspection, seems the only way to minimise the risks. The perfect freedom of an armoured-cable system, laid direct in the ground, from such accidents, is without doubt a very strong point in their favour.

In most "drawn-in," and in some "built-in" systems, it is necessary to either make service boxes opposite the houses as the cables are laid, or else to build such boxes with iron pavement covers, when required. Both are expensive methods. But with an armoured cable we need make no preparation for future service connections. Each case is dealt with as it arises, and by the use of a small split junction box of cast iron, placed around the cable and afterwards filled up with insulating material, the joints can be well and cheaply made.

So far what has been said will apply with equal force to either continuous or alternating current systems. But alternating current mains require special precautions to be taken in their design, which need not be considered at all in the case of those for continuous currents. It is most essential that adjacent wires should be protected from induced currents, and the remedy that suggests itself is to entirely surround the alternating current conductors by a metallic sheathing, such as an iron or a lead covering. This, however, would only remove the disturbances from the neighbouring wires to the sheathing itself. It would not prevent them altogether, but may, in fact, increase them, and so cause a great waste of energy. To stop them it would become necessary to place both the flow and return conductors within the same pipe or sheathing, and if the system were a three-wire one, then all three wires must be so treated. A perfect cure is only obtained when the conductors are so placed with respect to the pipe or sheathing that their centres are practically co-incident. A concentric cable meets this condition, either when drawn into an iron pipe or when lead-covered and armoured. I believe many alternating current systems are working where this precaution is more or less disregarded, and the amount of power lost through waste currents is unknown. Considering that these losses are going on all the time the station is running, they must amount to a good deal in the course of a year, and in some cases may probably equal the magnetising current losses of the transformers.

It would appear that this question is either not understood, or else ignored, by many who have to design alternating-current mains. In a recent case it was specified by a well-known engineer that three separate lead-covered cables were to be used for a three-wire alternating system. In the scheme which I am at present carrying out, the actual arrangement for the low-tension mains was left open, so that every contractor might tender on his own lines, and for his own system. It was distinctly pointed out that alternating currents were to be used on the three-wire system, and yet out of twenty different offers no less than nine had entirely overlooked the question of induced currents. Some firms proposed to use separate lead-covered cables, drawn into cast-iron pipes. Others offered separate lead-covered and armoured cables, to be laid direct in the ground. Others, again, proposed to use two concentric armoured cables, the middle wire of the system being divided and placed half in each cable. Of course, when the loads on the two sides of the system were such that no current flowed in the middle wire, each cable would act just as a single-sheathed cable. These proposals came from firms of the highest standing in the cable trade, and would show that there are many persons who have not yet fully grasped the importance of preventing waste currents.

As I said before, the three conductors must be under exactly the same conditions, and within the same pipe or sheathing, to entirely do away with the difficulty, and a triple concentric armoured cable meets the case perfectly. But when a triple concentric cable is used as a distributing main, the question of service joints comes in, and it is not the easiest matter in the world to make a good branch joint on such a cable. Not only are the branches to be pieced in, but the cable itself must be left continuous. The low-tension cable we have adopted in Bolton is made by Messrs. Siemens Bros. and Co., and consists of three separately insulated conductors twisted up together into one cable, and then lead-sheathed and iron-armoured. The effect of the twisting is to make the three conductors have practically the same centre. The making of service joints is much simpler than with a triple concentric cable, as when the sheathings are cut through each conductor becomes accessible, and can be treated as desired.

With reference to a three-wire system, it is often stated that when the load is equal on each side, no current flows in the middle wire. But although this is often true it is not necessarily so, as it altogether depends whereon the particular main the lamps are taken off. Suppose we have a three-wire main going out from a station or supply centre, and that close to the station 100 lamps are taken off on one side. At 150 yards away let another 100 lamps be taken off, but from the other side. Then our meters in the station would show equal current in the two outer mains, and we might assume that none was flowing in the middle wire; but for 150 yards of its length it would be carrying a current equal to either of the outer cables. This, of course, is an exaggerated case; but it will show that it depends upon the positions, as well as upon the numbers of the lamps, how much current flows in the middle conductor.

A point of great interest in connection with an alternating current scheme is, that although the low-pressure distributing network may be laid on the three-wire system, yet it is only necessary to have two-wire feeders. The transformers must be made with three terminals on the secondary coils, and the primary current will then adjust itself to the mean of the loads on the two sides of the secondary. If the transformers be designed so that there is only a 2 per cent. total variation in pressure from no load to full load, then the difference in voltage on the two sides of the system can never be more than 1 per cent. even in the almost impossible event of full load being on one side, and none on the other. In such a case the primary would take a current equal to half full load. This is of great practical importance, as the station machinery and switchboards can be arranged for a simple two-wire system, while all the advantages of a three-wire distribution are retained.

At all the principal points of inter-connection in the distributing network, junction boxes should be placed, so arranged that the various sections may be easily connected or disconnected for the purposes of testing, repairs, &c. Soldered joints would be here out of the question, so the cable ends should be sweated into thimbles, which may be clamped together, or to properly arranged connecting bars, as desired. If the insulating material be other than rubber, then the boxes may be filled up with oil to keep out the damp. The oil could be pumped out in a few minutes, when it was necessary to make a disconnection.

A very important point in connection with an underground system of mains is the question of insulation resistance. A badly insulated joint has a wonderful effect in producing bad results, and is practically equal to a faulty place in the cable. Therefore all joints should be most carefully watched while making, and a guarantee obtained from the contractor, rather of an insulation resistance when the cables are laid complete, than when individual coils are tested in a tank of water. Conductors of bare copper should only be used for continuous currents of low tension. The liability of all such systems to stoppage from water flooding, and the large sizes of the conduits required, are points against their use. Their only recommendation appears to be in the question of prime cost.

VARIOUS SYSTEMS OF UNDERGROUND MAINS AND METHODS OF LAYING SAME.*

BY S. V. CLIREHUGH, ASSOC. M.INST.C.E.

The author commences by stating that whilst the questions of direct coupled or rope-driven dynamos and the advantages or disadvantages of water tube boilers as against Lancashire boilers, and vertical engines as against horizontal engines, have been much discussed, the question of the best system of mains has been left severely alone. Having detailed the various points which the author considers desirable in a system of underground mains, he proceeds to consider to what extent these can be combined in any one system, and what are the various materials available.

There are, broadly speaking, three systems to be considered:— 1. Insulated cables in conduits. 2. Armoured cables. 3. Bare copper in culverts.

One of the oldest systems was that of laying cast-iron pipes into which were drawn insulated cables, boxes being built at first about every 80 yards merely for the purpose of drawing in the cables and making straight joints. This plan, in the author's opinion, is very suitable for a district in which it is difficult to ascertain the probable demand and which is served by a high-tension alternating current. With regard to the question of insulating material, cables insulated with vulcanised india-rubber stand no doubt from a scientific point of view at the top. In some places the difficulty offered by being unable to keep a "vulcanizer," is serious as the men are highly paid and on a small station there is not of course sufficient to keep even one fully occupied. In such cases it is sometimes necessary to use mechanical jointers, *i.e.*, cast iron boxes which are placed over the joint bolted together and filled with a bituminous compound. This makes a

* Abstract of a Paper read before the Northern Society of Electrical Engineers, March 12, 1894.

Digitized by Google

thoroughly good job but it is very difficult to break the joint should it for any reason become necessary. Another plan is to insulate the joints with pure rubber strip, and when there are sufficient number of them say 20 to 30 ready to be cured get the cable manufacturer to send a "vulcanizer" down for a week or so. A rough test as to whether a joint is properly cured is to try and mark the rubber when cool with the thumb nail, if it is just right it will yield to the thumb nail but leave no mark, if it leaves a mark it is undercured, and if it feels hard it is probably overcured. The only objections therefore to the use of cables insulated with indiarubber are practically its high price and the difficulties in jointing. The author specially warns engineers to be very chary of purchasing low priced rubber cables as it is almost impossible for anybody not an expert to tell whether the rubber is good or bad quality.

Bittite, the material used by the Callender Company, is believed to be bitumen refined to purity and vulcanised. The conductor is covered with a solid sheath of this material put on in one operation under pressure, and is served with a tape and covered with an insulating compound and again taped, then braided with a hemp yarn and passed through a bath of hot asphalte compound. Joints in the cables are insulated by wrapping the conductor with bittite which has been half vulcanised, up to the diameter of the original insulation, and then protecting it by a wrapping of compounded tapes. The joint is then heated by means of a lamp to make the wrappings solid and to complete vulcanisation. This system of jointing is very simple, and no particular training is required for the purpose.

Turning to cables of the second class, *i.e.*, the insulation of which is not in itself damp resisting, but which has to be protected by a metallic envelope, the author states that he feels some difficulty in expressing himself lest he should appear prejudiced, as he was for two years engineer to the British Insulated Wire Company, whose speciality is fibrous insulation applied in the form of a paper. The question is whether a fibrous cable will answer as well as a rubber cable. Decidedly yes, if we are prepared to treat it with sufficient care. Very frequently, however, fibrous cables get into the hands of jointers who have been given no special instructions, and they treat it as they have been accustomed to treat a cable insulated with indiarubber, with, of course, unsuccessful results. Fibrous cables are not so flexible as those insulated with indiarubber, but for nearly all practical purposes they are quite flexible enough.

The manufacture of lead-covered fibrous cables is fairly well known. The fibrous material, be it in the form of yarn or paper, is laid spirally round the cable, pressure being applied to solidify the mass as much as possible to the required thickness, the cable is then thoroughly dried out at a temperature of about 250°Fahr. for 30 to 40 hours to expel every possible trace of moisture, and it is then immersed in wax, resinous oils, or similar materials at a high temperature. From this tank, without any further contact with the air, it is passed through a lead press and so hermetically sealed. The great danger in these cables to guard against is the possibility of the formation of "pinholes" during the process of lead covering. These are produced by a variety of causes, but probably the most troublesome one is produced by impurities in the lead. These "pinholes" are very difficult to perceive during manufacture, but they are generally found by testing after prolonged immersion under water. It is very important in buying this class of cable to find out what insulation resistance the manufacturer recommends, and to see that all cables of the same class have approximately the same insulation resistance after one minute electrification and 24 hours immersion in water. The electrification being very marked in this form of cable, it is essential to see that this limit is adhered to.

The author states that he has found by experience that it is better not to insist upon too high an insulation resistance, but to insist on its being uniform. Cable manufacturers are a good deal bothered by having high insulation resistance specified. It can be produced if desired, but at the expense of the life of the cable caused by excessive drying out. The pressure test is a very useful one, and cables of this class should certainly be tested after immersion with at least double the pressure at which they are intended to work. The cables should again be tested for insulation resistance, and the result should be the same as before the pressure was applied.

Coming to the treatment of the cables after they are delivered in the streets the author assumes they are to be drawn into cast-iron pipes. Cables which are to be thus treated should be either taped or braided outside the lead, preferably the latter, to prevent any roughness in the pipe scoring the cable. If the cable is a heavy one, some lubrication is often desirable, and for this purpose there is nothing better than soft soap. In a straight run with a moderate-sized cable 80-100 yards may be drawn in in one length, great care being taken to avoid kinks or sharp bends. It will be noticed that the end of the cable is sealed up, and when this end is cut it must be resealed as soon as possible, as the insulation being very hygroscopic, the insulation resistance of the cable is quickly lowered if the end remain exposed too long to the atmosphere. A good temporary way of sealing the end of a cable is to lap it with dry cotton tape and plunge it into hot pitch.

Samples of fibrous cable joints in various stages of manufacture were shown by the author. Other things being equal, paper insulation has, the author thinks, an advantage from the fact of its cleanliness in jointing. The power of paper as a dielectric for resisting disruptive discharges is very high, and ¼in. radial thickness of insulation has been found sufficient to withstand a pressure of 20,000 volts.

The author then refers to Brook's oil insulation system, which he is of opinion might be suitable for feeders, but difficult to work on a system of distributing mains.

The principal object in the use of armoured cables is their supposed cheapness, which, however, is overrated. They may be of service in outlying districts, and possibly in some cases for feeders, but there are many drawbacks to their use, one of the principal ones being the difficulty of fault finding, as in any draw in system whenever the fault is arrived at within say 20 yards that length of cable can be drawn out and examined at leisure whereas with an armoured cable you have to open many yards of ground before you actually arrive at it.

Messrs. Crompton and Co. are the great exponents of bare copper in conduits. The culvert consists of a concrete trench laid under the footway. The culverts are constructed of cement concrete the wall in no case being less than 6in., and the bottom 4in. They are covered with York stone bedded in cement, and the culverts are rendered inside with cement thus making it thoroughly waterproof. Boxes are built every 15 yards along the trenches and these are the only places in which the cable is supported so that the insulators are always open for inspection. The insulators are mounted on oak crossbars (which are mounted on the concrete about 2in. off the bottom) and are made with a notch in the top on which the conductors rest. The culverts are connected where possible to the main drains. It might be thought that a film of moisture would collect on the insulators, thus giving rise to considerable leakage, the electrolytic action of the current however is said to be sufficient to resolve this moisture into its two component gases. We seem here to have a system which combines most of the desired qualities in a system of mains, however this has its drawback like all others. Firstly, in many of our great cities it is impossible to find room for this class of conduit, and then recourse is had to insulated cables. Secondly, a water main bursting might possibly cause a stoppage of the supply, this, however, is not very likely to happen. Thirdly, gas is apt to accumulate in the conduits, giving rise to explosions, it is however less likely to get into a water-tight conduit than into a system of iron pipes where there is no attempt made to keep out the water. Whether bare conductors are more likely to ignite the gas is a much debated question. Only recently two of the technical papers had an article on the subject, one said it is easy to see how the gas gets into the conduits, but what fires it; the other, however, wondered how the gas got in, but understood how once in, it was fired. The author is inclined to believe that most explosions occur from lighted matches, candles, &c., being introduced into the boxes. As regards the life of this culvert system, it seems that we have at least got hold of materials which have stood the test of time, viz.—oak, concrete, and copper.

ON PARALLEL WORKING, WITH SPECIAL REFERENCE TO LONG LINES.*

BY W. M. MORDEY.

In his reply at the end of the discussion on his Niagara Paper, Prof. Forbes alluded† to some experiments which he had witnessed, and which he considered showed that alternators of my design would not run properly in parallel. The passage is as follows:— "At the time when I recommended the Mordey machine I said that, before deciding to adopt it, tests must be made with a resistance between the dynamos in parallel. Does Mr. Mordey forget that, when he kindly placed at my disposal the means of making this test, by putting 'Sunbeam' lamps in series—that is to say, between the two dynamos working in parallel—the lamps went up and down in brightness with the periodicity of a few seconds, and that the tendency was to rise to maximum brilliancy, showing that the dynamos were rather working in series than in parallel? From the moment of those experiments, I felt that that type of machine was not suited for our purposes, though I never mentioned that until I was compelled to by Mr. Mordey's claims for his special mode of working." I heard his remarks with the utmost astonishment, as the experiments, rightly interpreted, appeared to afford the very strongest proof of the exceedingly powerful synchronising effort exerted by these machines, and because I then

* Paper read before the Institution of Electrical Engineers, March 8, 1894.

† *Journal*, XXII., 607.

Digitized by Google

heard a contrary view expressed for the first time. And in another passage Prof. Forbes stated that they must have alternators at Niagara that will run without any synchronising or waste current.

The matter is of some moment, and demands an explanation. With your permission, I will make this explanation the text and starting point of a Paper on parallel working, and on the allied subject of the use of alternators as synchronous motors. The experiments were made in July, 1891, and were the subject of a leading article in *The Electrician* of July 16, 1891, and were mentioned in the *Electrical Review* and elsewhere, in each case as having afforded an illustration of the thoroughly satisfactory parallel working of alternators when directly coupled to high-speed engines—a matter with regard to which there was at that time some uncertainty. It had been supposed that some flexible or yielding coupling was necessary between the engine and alternator. For my own part, I never had any doubt on the subject; but in order to place the matter beyond dispute some tests were carried out by the Brush Electrical Engineering Company and Messrs. Willans and Robinson. The former provided two of my alternators, the latter fitted them to two Willans engines. Amongst others, Prof. Forbes received an invitation to witness the trial, and was present.

When all the tests of ordinary parallel working had been satisfactorily carried out—including shutting the steam off the engine driving one of the alternators, and then applying a brake to its flywheel in a vain attempt to force it out of step—a further test was made (as an interesting experiment bearing on the subject of synchronous motors) to ascertain what would occur if the two alternators were coupled together with a resistance between them so great that the resistance alone would be sufficient to absorb the whole power of one machine, even if the machine at the other end were at rest; and the remarkable fact was established that even under these conditions (which would be absolutely absurd or impossible in practice) the two machines did not break out of step.

The resistance used consisted of "Sunbeam" lamps, which happened to be the only suitable resistance available. These lamps, being made for 80 volts and about 5 amperes, would have a resistance, hot, of about 20 ohms each, and a much higher resistance when cold—probably more than 30 ohms. Seven of these lamps were placed in series between the alternators. There was no other external circuit. It was then found that there was a current passing through them which rose and fell with a slow pulsation; the alternators, although not actually breaking out of step, evidently getting a good deal out of true co-phasal synchronism, and only being pulled in when this slowly pulsating current rose to a considerable amount. Synchronism being regained, the current decreased again. This current was not measured, but was probably about 7 amperes, as the lamps were a good deal over-incandesced. The experiment was then discontinued.

Properly interpreted, this test appeared to show that, even when a line of an enormously high resistance was interposed between two alternators arranged to run in parallel (or one as generator, the other as synchronous motor), and when no adjustments were made to help them to keep together, the tendency to get out of step was corrected with a surprising amount of success; the correction, instead of being instantaneous and powerful, as with machines connected through a small resistance only, being sluggish, and greatly weakened by the effect of the very high resistance of the line. To show how utterly unfair and unjust Prof. Forbes's interpretation is, and to reassure those who may desire to use synchronous motors, it is only necessary briefly to examine the conditions of the test.

The two alternators used in the experiment were 37·5-kilowatt 2,000-volt machines. At full load each would therefore give nearly 20 amperes. Now, suppose it is desired to run one machine as a generator, driving the other as a synchronous motor (to take the illustration that may best suit the case of power transmission over a considerable distance), it will be seen that, if the line is to be designed to give such a percentage loss as is proposed for the Niagara-Buffalo transmission (that is, 3·5 per cent.),* the loss at full load should be 70 volts, and, the maximum current being, say, 20 amperes, *the line resistance should be 3·5 ohms*. In the actual experiment, the machines did not break out of step even when the line resistance was *more than* 100 *ohms*—that is, relatively more than thirty times greater than Prof. Forbes proposes to use even for his long-distance transmission. This is the more striking as a proof of their powerful synchronising when it is considered that, even if it had been intended to expend the whole power of the generator in the line, that line should only have had a resistance of 100 ohms. That these machines did not act quite perfectly in parallel under these conditions, even with no load, is not to be wondered at. The only cause for surprise is that they exerted any sensible synchronising effort at all. It is exactly as if an attempt had been made to run two 1,200-kilowatt alternators in parallel through a line constructed to allow a reasonable loss for a couple of 40-kilowatt machines. Even unloaded, such a test would be unreasonable.

* *Journal*, XXII., 516.

I now wish to refer to the "hunting" or regular pulsation of current, shown by the slow changing of the lamps from blackness to high incandescence, which is a matter of considerable interest. It may have been caused by self-induction, or, as, in this connection, it is sometimes termed, armature reaction—that is the effect of the self-induced field produced by the armature in disturbing the impressed field of the field-magnet. Although this effect may in some cases be considerable, I think we must look elsewhere for it in this case, because in the machines in question such reaction would have been inconsiderable, even if the phase relation had been most favourable to it. This I may illustrate by saying that if the armature current had been commuted, and passed round coils on the field poles having turns equal in number to the armature coils, the effect on the field would have been inconsiderable.

I think an explanation of the "hunting" will be found in the character of the resistance, and in the governors of the engines. The change in the resistance of the lamps accounts largely for the pulsation. When black they would interpose a very high resistance—probably about 200 ohms—then, as the machines got a little out of step, the synchronising current would heat them, reduce their resistance, allow a much readier transfer of power, and so bring about a restoration of true synchronism, and a reduction of current through the lamps. This series of effects, being constantly repeated, goes a good way towards explaining the pulsation. Probably without this lowering of the resistance by the incandescing of the lamps, synchronism would not have been maintained at all. Then, again, the governors of the engines must be considered. If they pulsated with the same period, but opposite phase, the action is explained; they would, at any rate, accentuate the "hunting," if they did not start it. Messrs. Willans and Robinson have kindly sent me an indicator card, taken by Mr. Willans at the time, which supports this view, the steam being shown as having been widely varied during the taking of the card. This must not in any way be taken as a reflection on the governors. The conditions were very trying for any governors, there being no load, and no opportunity occurred of specially adjusting them. If we had governed by hand at the stop valve, this "hunting" would not have occurred. Nor would it have occurred if we had adjusted

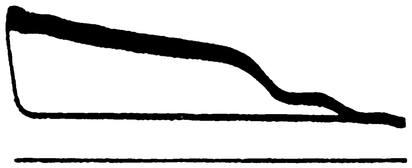

Fig. 1.

the E.M.F. of one machine so as to allow it to run as a motor all the time. What happened appeared to be a repeated change in the functions of the two machines, from generator to motor—first one racing, and then the other, driving the second one as a motor.

The condition of entire absence of synchronising current or of correction can only be obtained by driving by engines that are very even in power always. I think this is more likely to be approached by turbines than by reciprocating engines. By "synchronising current" I do not mean necessarily an actual current passing from one alternator to the other—this only occurs when one of them is driven as a motor—I mean the variations of the current contributed by each machine to the circuit. But I would like to point out that the condition laid down by Prof. Forbes as an essential—namely, that they must have alternators at Niagara that will run without any synchronising or waste current—is an absolute impossibility. Alternators will run without synchronising current only when there is no necessity for them to exert any synchronising effort. However, I am glad to find that Prof. Forbes has set himself to solve this problem of getting an alternator motor to run without any current (for that is what it amounts to), because I am sure that in solving it he will also have disposed for ever of that other interesting problem—making a motor that will run without any back E.M.F. This is a new and significant outcrop of the "perpetual motion" idea. I am sure that if Prof. Forbes had really considered or understood this matter he would not have expressed the opinion which I have quoted. At the same time, I wish to say I am convinced that his criticism was not unfair by intention.

The necessity for correcting a false impression has forced me to take the first opportunity of bringing this matter before the Institution. I regret that Prof. Forbes is abroad, but he will of course have an opportunity of sending on for the *Journal* any observations he may wish to make.

It was not my intention to do more than make the above explanation, feeling sure that it would be sufficient to enable the Institution to form a correct judgment on the circumstances; but as I am permitted to occupy more of your time than I expected, I wish to refer to some tests that I have been able to make. It

Digitized by Google

appeared desirable to give the results of actual trials, preferably working one machine as a synchronous motor, and not merely as one of a pair of parallel connected generators. It will be granted that the action of synchronous motors and of parallel alternators is very similar. But with regard to the trials just referred to it might fairly be argued that as each alternator had a steam engine behind it, on which it could fall back for assistance, something more is wanted to actually prove that the explanation is applicable to the case of a synchronous motor relying entirely on its own motor properties. I am, therefore, glad to be able to place before you the results of some tests made in the works of the Brush Company.

Some Tests of a 25-Kilowatt Mordey-Victoria Alternator Used as a Motor.

This test was carried out by my instructions on February 18, 1891, four months before that witnessed by Prof. Forbes. A 2,000-volt 25-kilowatt alternator was run as a motor, driven by a 37·5-kilowatt generator. The motor drove a dynamo which was loaded until the alternator motor was taking about its full normal current, it being assumed that this represented full power. Separate tests* have proved this assumption to be justified. The following readings were taken with a resistance of straight platinoid wire between the machines :—

Test A.

Volts. Generator terminals.	Volts. Motor terminals.	Amperes.	Resistance in line. Ohms.
2,340	2,002	13·74	32
2,358	1,932	13	48

The volts of the generator were raised above the motor volts sufficient to supply approximately the line loss.

This test was quite satisfactory, and of course settled, so far as we were concerned, any question that might at any time arise as to power transmission over long lines by synchronous motors—a matter that was from time to time coming up in connection with proposed installations. As a result, I always considered it quite safe to quote for work up to a line loss of 20 per cent. But, my attention being recalled to the subject by the extraordinary statements of Prof. Forbes, I took the opportunity, after writing the foregoing explanation, to make some tests having a particular bearing on the details of the question before us. In some respects they are rather wanting in completeness—I was not always able to carry them as far as I wished—but I feel sure that you will approve of my supplementing my explanation by an account of such tests as the facilities at my disposal at the moment rendered possible.

Tests of 50-Kilowatt Alternator as a Motor.

The object of these tests was to ascertain the effect of inserting resistance between two alternators one of which ran without load as a synchronous motor. It was desired to find—

(*a*) What resistance was required to cause the motor to fall out of step ; (*b*) How much the current varied ; and (*c*) Whether any "hunting," or pulsation, was set up. Two similar 2,000-volt 50-kilowatt alternators were used.

Generator.—This was driven by a separate engine capable of working it up to full load. It was run without governor, and controlled by hand at the throttle valve.

Motor.—This was started and brought up to synchronism by a small direct-current motor, driving by a belt which was thrown off as soon as the large motor was running synchronously.

The two machines were excited from a separate dynamo, their fields being in parallel. The E.M.F. at the generator terminals was measured, and the current from armature to armature. The field currents were not measured, nor the E.M.F. at the motor terminals. The generator was excited to give 2,000 volts, and then the motor field was adjusted till the current received by the armature was a minimum. This will be understood from Fig. 2, which is reproduced from a Paper I had the honour of reading before this Institution last year.† It may be remembered that I showed that there is a well-marked excitation that reduces the armature current to a minimum for any given load, and therefore gives a maximum power-factor and maximum efficiency. If the excitation be varied on either side of that value, the armature current taken by the motor rapidly increases.

In working a motor it is desirable always to adjust the excitation till the bottom of this V curve is reached—that is to say, until the armature current is a minimum. In the case before us this current was found to be 1·5 ampere. Having got this, the excitation was not disturbed, and the following readings were taken :—

Test B.

Volts at generator terminals.	Current.	Resistance in external circuit between generator and motor.	Remarks.
2,000	1·6	0	Current steady.
"	1·6	10	"
"	1·6	20	"
"	1·7	35	"
"	3·5	63	"
"	3·6	69	Current rather unsteady.
"	5·3	77	"
"	...	90	Current increased rapidly at this point, and the motor slipped quietly out of step.

In the first place, it is to be noted that there was no "hunting," or pulsation. The unsteadiness of the current was not regular. Examining this test with a view to its practical aspects, it will be seen that it fully supports the explanation given at the commencement.

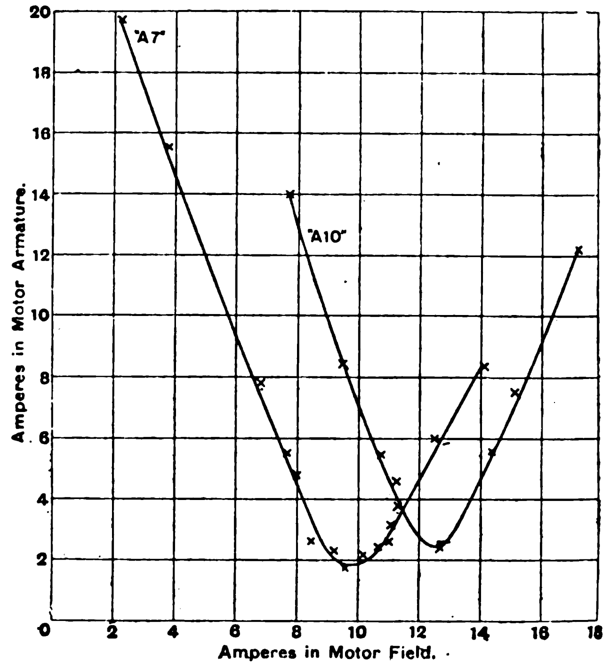

Fig. 2.

Applying to it a similar comparison, we see that, as the alternators were 2,000-volt 50-kilowatt machines, a line proper to these, in order to comply with the Niagara-Buffalo condition of allowing a loss of 3·5 per cent. in transmission, should have a resistance of

$$\frac{2{,}000 \times 3\cdot5}{25 \times 100} = 2\cdot8\ \omega\ ;$$

and that the resistance of external circuit that would be sufficient to dispose of the whole load of the generator, supposing it to be merely working on that resistance as a load, would be

$$\frac{2{,}000}{25} = 80\ \omega.$$

Exactly as in the case of the trial witnessed by Prof. Forbes, we find that a resistance of about 30 times a reasonable working amount had to be inserted before synchronism was interfered with, and it will be observed that more than 20 ohms had to be inserted before any effect appeared to be produced.

But it may be said that the line loss, even with this enormous resistance, is comparatively trifling, as the current is not large, and that there ought to be plenty of power left to keep the motor in step. There *is* plenty of power, but it cannot be applied to the motor advantageously. The line loss, even with 5·3 amperes and 77 ohms, is only 408 volts and 2,156 watts (I am considering only resistance and current), whereas the generator was capable of supplying 50,000 watts. But it must be remembered that the E.M.F. of the motor being kept up, it can only receive current under these conditions by letting itself get partly out of phase (and so into a disadvantageous position), and that then every increase of current intensifies the evil by causing a further

* *Journal*, XXII., 127.

† "On Testing and Working Alternators," *Journal*, XXII., p. 128, February 23, 1893.

Digitized by Google

loss of volts on the line, and therefore a further reduction in the E.M.F. impressed on the motor. Had I lowered the E.M.F. o the motor, or increased the E.M.F. of the generator, the line resistance could have been still further increased without loss of synchronism. Such a change of the relative E.M.F.s of the motor and of the generator would have allowed current to get into the motor against the lower ordinates of its E.M.F. waves, without the necessity for any serious shifting of phase. If the motor E.M.F. had been lowered in this way the driving current would have increased, and synchronism would have been maintained much longer and through a higher line resistance, and would finally have been lost by the power being wasted in the line, and by "armature reaction" on a weakened field.

Or, again, if the excitation of the motor had been raised, it should be found that it would go out of step with a smaller external resistance than before. This matter is of practical importance, as perhaps others than Prof. Forbes may wish to work through a line 30 times too long, and therefore some tests were made to prove the truth of this explanation.

Test C.—The machines were run under the conditions of the fifth line of the readings given above, that is, with the excitation as before, and with an external resistance of 63 ohms, the current being 3·5 amperes. The excitation of the motor was then increased, probably about 20 per cent. Before there was time to take any reading the motor went out of step. This was satisfactory, as proving the correctness of the explanation.

Test D.—Another test was made with the motor acting as a dynamotor in the manner shown in Fig. 3.* One half, M, of the

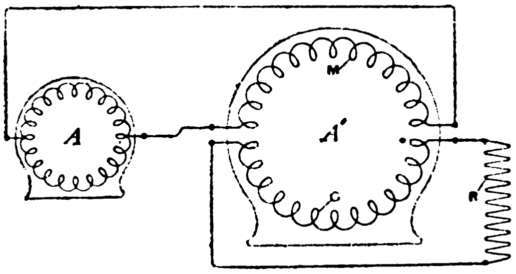

FIG. 3.

armature winding was used as a motor; the other half, G, as a generator working on a separate circuit, R. In this instance a load of 5 amperes and 2,000 volts was put on this generator portion, the lowest armature current being obtained with an exciting current of about 11 amperes. The field of this dynamotor was then reduced from 11 to 6 amperes, but it did not show any signs of getting out of step. The driving current rose to 15 or 16 amperes. But on increasing the dynamotor field to 17 amperes it went out of step, the driving current being about 15 amperes. This test is not on all fours with the other, as there is the effect to be considered of the varying load on G, but it is a confirmation in a general way of the explanation.

Test E.—A test was then made to find, when working with no appreciable resistance between the machines, whether any "hunting" or pulsation was set up by varying the excitation of the motor till the armature current rose considerably up either slope of the "V." On decreasing the excitation till the armature current rose from 1·6 to 6 amperes the current became rather unsteady or irregular; the motor evidently getting a little out of step sometimes, and being pulled in by slight rushes of current of very short duration, which probably over-corrected the irregularity, causing the machine to run for an instant without current, or to act as a generator and itself to give current—that is, to act as an electro-mechanical fly-wheel, converting mechanical to electrical energy, and *vice versâ*. On increasing the excitation again, passing the bottom of the "V," and rising up the opposite slope to the same height (about 6 amperes), it was found that the current was rather steadier than under the conditions last noted; that is, when the current was about 6 amperes it was rather more unsteady in a strong field than in a weak field. The explanation of this difference is that with a weak field the motor could receive current during its whole phase; whereas with a strengthened field the E.M.F. waves would be higher than those of the generator and some want of co-phasal synchronism would be needed to allow current to get in. In neither case was there any "hunting" or regular pulsation of current.

(To be concluded.)

The Salève Electric Railway.—The Geneva papers announce the opening, on the 4th ult., of the last section of the electric railway to the summit of the Salève, about 5,000 feet above sea level.

TELEPHONE RATES IN THE VARIOUS COUNTRIES OF EUROPE.

The following particulars about the rates for telephones in various countries may be of interest:—

In Austria-Hungary the rates are uniform for all the State telephone exchanges. The State telephones cover the whole of the country, except the city of Vienna. The total charge is made up of an installation charge, which for a distance of not above 500 metres amounts to £5 (50 gulden), and for every additional 100 metres £1; then there is annually a station charge of £3, and what is called a working charge of £2, so that the annual charge is about £5.

In Switzerland the charge has been by degrees reduced to about £3. 3s. (80fr.) As a result of this low tariff the number of telephones has rapidly increased, and at the end of 1891 there were about 12,595 telephones.

In France the telephones are a State affair; the annual charge for towns with over 25,000 inhabitants is £8 (200fr.), and for smaller towns £6 (150fr.)

In Italy the telephones, in accordance with the Telephone Act of 1892, may be worked either by the State or by private enterprise. For the smaller and medium-sized towns the annual subscription ranges from £5 to £6.

Sweden boasts of an exceedingly well-managed and greatly developed telephonic system, which comprises both an extensive and ever growing State telephone system and numerous private concerns. The rates are on the whole very reasonable; as a rule, a subscription of £4. 10s. will cover an area of about a mile from the exchange. For smaller towns the rates are somewhat lower (£1. to £1. 10s.). Private companies have as low annual subscriptions as £1. 13s.

In Norway the subscriptions vary according to the size of the towns, but are on the whole moderate; they range, as a rule, from £2. 4s. to £4s. 9s. It is at present under discussion to erect a very extensive system of State telephones in Norway.

In Spain most of the telephone companies are private concerns; the annual subscriptions vary considerably, say from £3 to £11.

In Holland, the Netherlands Bell Telephone Company has almost monopolised the telephones, and the subscriptions are fixed according to the size of the towns. In Amsterdam, for instance, the subscription is about £10 (118 gulden); in Rotterdam, £10; in Grovenhagen, about £8. 10s. (110 gulden); in Haarlem, Utrecht, Arnheim, Groningen, and Zaandam, which are towns with something like 30,000 inhabitants, only £5 (60 gulden). In still smaller towns the annual subscriptions are reduced to £4 or £3. 10s., and even these low charges are subject to further reductions by contracts extending over several years, &c.

The telephones of Belgium are partly State and partly private affairs. There are no uniform subscriptions, but the charges are registered according to the distance from the central station, and the term of subscription. The charges for the State telephones are, for a distance from the exchange of 1 kilometre, £6. The usual charges for private companies vary from £5 to £6. In Luxemburg the charges vary between £3 and £4.

In Luxemburg the charges vary between £3 and £4.

In Denmark the Copenhagen Telephone Company, which through a State telephone cable has connection with Sweden, charges about £8. 6s. 6d. (150kr.) annual subscription. The subscriptions in the provincial towns vary considerably, from about £1. 12s. 6d. to £4. 4s.

In Germany the telephones are almost exclusively State institutions, and the charges are on the whole high.

In England, finally, the National Telephone Company charges from £20 annually in the City of London down to £10 or £8 in smaller towns.

LEGAL INTELLIGENCE.

Muirhead v. The Commercial Cable Company.

MONDAY, MARCH 5TH.

On the hearing of the case being resumed, Mr. J. SWINBURNE was sworn and examined by Mr. Moulton.

WITNESS was of opinion that Fig. 1 of the 1880 patent (*see* p. 528 last issue), and Fig. 1 of the 1876 patent (*see* p. 529 last issue), were electrically the same. He took it that the V-shaped resistance in 1876 meant any convenient way of adjusting electrically. Electrically there was no difference between the function of circular rheostats, working with a handle, and coils plugged out by moving plugs. The nomenclature was rather loose. For instance, in Gordon's treatise on Electricity, published in 1880, there was an illustration of Sir William Thomson and Mr. Varley's slide coils. The letterpress showed that Sir William Thomson and Mr. Varley had arranged a resistance box where the resistances were varied. Then an illustration of what in the present action would have been called a rheostat was given, it was a rheostat

that went up to 100,000 ohms. The essential part of Fig. 2, of 1880, was the insertion of the condensers in the bridge arm. Fig. 3 of 1880 was the same as Fig. 2 with the resistances r^1, r^2, reduced. Speaking as an electrician he did not see any difference between Figs. 2 and 3 of 1880 and Fig. 2 of 1876. Fig. 2 of 1876 was shown more diagrammatically.

Cross-examined by Mr. Bousfield, WITNESS admitted that he had had no practical knowledge of duplex telegraphy until he took it up in reference to the action. In 1876 he was serving an apprenticeship as an engineer. He did not take up electricity professionally till 1881. In 1876 he did not know what duplex telegraphy was. His view was that because there was a balance to be adjusted that it must be meant to be done in Fig. 1 by adjusting the resistances in the arms. He should not have thought that the whole of the pictures in the 1876 patent were consistent with the view that by those curly wires the inventor meant to imply fixed resistances and not adjustable ones. He should not think it possible to obtain an adjustable balance in Figs. 4 and 5 of 1876 without adjusting the bridge wires proper. The artificial cable was meant to be a copy of the real cable. It was easy enough to make the whole resistance of the artificial cable right. It was easy enough to make the whole capacity of the artificial cable right. But the resistance and capacity are not necessarily distributed in the same way along the length of the artificial line as along the length of the cable, and such discrepancies would cause little kicks in the receiving instrument.

Mr. BOUSFIELD: Now I ask you whether or not, in fact, the rheostat actually used in accordance with Fig. 3 of 1880 does not furnish what you have spoken of as the last refinement?—No, I think not.

You are speaking now with some confidence about what would be read out of a specification of 1876. I ask you, having regard to the state of knowledge at that time, was not the use of the rheostat in the 1880 patent to give a final adjustment of the smallest kind which was never dreamt of being got at all so far back as 1876?—No, I think not.

Continuing, WITNESS stated that adjustable resistances in the bridge arms gave no capacity adjustment. The adjustment shown in Fig. 4 of 1876 might give the same sort of adjustment as he had suggested ought to be got by an adjustable resistance in the bridge arms. Counsel then quoted Mr. Preece and Mr. Sivewright (1876), and witness admitted that the adjustment there was obtained by what was called a rheostat. But witness could not agree that that was the sort of arrangement the patentee described in 1876 in his patent. There was no question of capacity so there was no difficulty whatever in adjusting the resistance of the artificial line as a whole. The land duplex and the cable duplex were alike in that, in both cases they had to make a resistance adjustment. But in the case of the submarine duplex where one had an artificial cable with capacity, they could not adjust the resistance of the artificial cable, without throwing the capacity adjustment wrong.

Mr. BOUSFIELD: Take Fig. 4 or Fig. 5 of the 1876 specification: cannot you by either of those methods make the resistance adjustment without altering the capacity?—Quite so. You can. But those are not the same as that figure in Preece's book. In Figs. 4 and 5 you do not adjust the resistance of the artificial cable.

Witness was then cross-examined at considerable length as to the alleged advantages of employing a rheostat and as to whether or no a condenser in the receiving circuit was a matter of common knowledge in 1876.

Re-examined by Mr. Moulton, WITNESS stated that there was no electrical advantage in using a circular rheostat which could not be obtained by adjusting the resistances in other ways.

Mr. H. R. KEMPE, examined by Mr. Moulton, stated that he was a Technical Officer of the Engineer-in-Chief's office, General Post Office, under Mr. Preece. He had been 22 years in the engineering department of the postal telegraph office. He was acquainted with the land-line duplex upon its first introduction into the Post Office about 1873. He had no practical experience with submarine working duplex. Looking at Fig. 1 of 1876 a competent electrician would have understood that the two arms were to be adjustable in some way or other—either two arms, or artificial cable, or both. Circular rheostats were in use in 1872. Looking at Fig. 2 of 1880, in his opinion, in order to obtain the effects of such an arrangement, it was not necessary that the rheostat should be at the vertex.

Cross-examined by Mr. Bousfield, WITNESS stated that in his opinion the rheostat was no use at all. He had made experiments in a laboratory only a few days ago to try whether the rheostat itself made any difference, but it did not. He had never been to offices where cables were practically worked. In his view it was absolutely unnecessary to have the resistance in the arms of the bridge adjusted if they had condensers there. The daily temperature and atmospheric changes which occurred, where land lines were concerned, were to a large extent absent where cables were concerned. Nevertheless he thought that in the year 1876 the importance of having a daily adjustment for small changes in the submarine duplexing must have been foreseen. As regards Fig. 2 of the 1876 specification, taking the full line figure, he thought it might work perfectly on a short submarine line—a cable 200 miles long—without requiring any provision whatever for adjustment. Possibly in regard to Fig. 2 when the apparatus was finally set up and finally balanced in a cable 200 miles in length, there would be no further requirement for variation. Witness was then examined at some length with regard to some statements contained in Mr. Preece's Presidential Address of last year, in which he stated that although in 1877 duplex working on land lines was fairly good, the imperfect balancing of appliances at their disposal made duplex working to Dublin very unsatisfactory; whilst in 1884 a single signalling condenser was applied to duplex circuits, and the balance condensers were divided into three adjustable portions, with the result that the duplex speed to Dublin was raised to 140 words per minute. Witness said that referred to automatic fast-speed working on what was practically a land line, which was different to ordinary cable signalling.

Mr. JOHN GOTT, examined by Mr. Moulton, said he was a telegraph engineer and electrician to the defendant Company. He had had 33 years' experience with submarine telegraphy. In 1876 a competent electrician, looking at Fig. 1, would adjust the arms of the bridge. That was common knowledge at the time. Fig. 2 was an improvement on Fig. 1, the improvement being the placing of the condensers in the bridge arms. In the specification of 1880, Fig. 2, it made no difference in the effect produced having a rheostat at the vertex, or having a rheostat or resistance coils adjustable in the arms. Before 1876, in experimental duplex submarine working he had used the receiving condenser. In Fig. 3 the rheostat did not produce any different or other effect than it did in Fig. 2. In practice it was immaterial to keep the resistance of the arms constant. In working, key K was to earth. In practice they generally put the end of the artificial cable to earth through probably 10 ohms. A current passed down K when they were receiving. In the ordinary arrangement of the bridge, if the instruments were taken from the usual place, and placed in the circuit of the key, one would get as good signals there as one would in the ordinary position.

Cross-examined by Mr. Finlay, WITNESS stated that by the Muirhead 1880 duplex system a 10 or 15 per cent. improvement was obtained over the duplex system hitherto in vogue—*i.e.*, 95 per cent. over the simplex system.

Re-examined by Mr. Moulton as to the number of adjustments wanted in a day's duplex cable working, WITNESS stated that all the adjustments were made early in the morning before commencing work, and then there were three or four or five adjustments a day at the outside. They could make the adjustments just as finely with plugs as with any other arrangement.

TUESDAY, 6TH MARCH.

On the hearing of this case being resumed, Mr. FRANK JACOB, examined by Mr. Moulton, stated that he had been for the last 21 years in the service of Messrs. Siemens Bros., and had been for the last 15 years their chief electrician and sole electrical adviser. He had had experience in the manufacture of cables, and the laying of the cables. Looking at Fig. 1 of 1876, he would have understood the curly lines to represent resistance, the word "bridge" would mean that they must be adjustable. Electrically there was no difference between the circular thing with a handle and the square box with plugs. In Fig. 1 of 1880, supposing the adjustable resistance were put in one of the arms, the instrument would work equally well, there was not the slightest practical importance in keeping $r^1 + r^2$ constant. In his opinion there was no difference whatever between the invention shown in Fig. 2 of 1880 and in the 1876 patent.

Cross-examined by Mr. Pollard, WITNESS stated that he would not take it that the 1876 patent, taken as a whole, assumed that whatever had to be done had to do with high resistances in the arms.

Sir HENRY CHRISTOPHER MANCE, examined by Mr. Moulton, stated that he had been connected with submarine telegraphy since 1863, and gave evidence in the same sense as the previous witness as to the meaning of Figs. 1 and 2 of 1876, the immaterial nature of the exact locus of the rheostat, &c.

Mr. FINLAY: Take the alternative arrangement of *m n* with the condensers on the far side between the receiving circuit and the cable and the artificial cable respectively; these condensers will not enable you in any way to reduce resistances in the arm?—I do not know what the arms are supposed to have been then.

You have got the arms shown with the coils and resistances. I ask you whether it is not the case that if you put the condensers on the far side of the receiving circuit these condensers in no way help you to reduce the resistance on the arms?—Therefore I should put it on the other side myself.

Do you agree that that is so, that if they are on the far side they in no way help you to reduce the resistances in the arms?—They would not help you.

Now do you mind looking at page 3, line 26:—"In this method of working the terminals of the receiving instrument may be connected on the line side of the condensers with the cable and artificial line respectively as shown at *a b* (Fig. 2), or the receiving instrument may be connected with the opposite poles of the condensers on the bridge side as shown by the dotted lines *m n* in the same figure. I prefer the latter arrangement." You would prefer, you just told us, the former?—Yes, the other.

Mr. JUSTICE KENNEDY: Then it reads as if the inventor had made a mistake there, because he certainly attributed it to both.

The WITNESS: Probably he wished to do away with the condenser in the receiving circuit. I think that is possibly what might have been in his mind when he said that.

Mr. MOULTON then stated that all the evidence for the defendants had been given, and proceeded to review the case. A patent meant, he said, one and the same thing, whatever the form of litigation, and whoever the litigants. If that were borne in mind a great part of the points which had been raised in cross-examination of his witnesses or in examination of the witnesses on the other side, with regard to the patent of 1880, would disappear. The position of the Court was just the same in interpreting the grant as if it were an action for infringement of the 1880 patent. In that case what witness would have ventured to come up and say that it was a question of turning a handle instead of putting a plug, which was to get a man out of infringement of the patent. They had got to believe, first, that the patentee tied himself down to something so narrow that it could be avoided, without in the slightest degree losing the benefit of the invention, and secondly that the courts were going to be so blind that they would not apply in defence of the patentee the common knowledge of every electrician in order to protect his invention being stolen by a trivial alteration which anybody, even the merest beginner, could have made. The evidence put forward proved that

Digitized by Google

that very issue as to the particular position of the adjusting device was immaterial in getting the benefit of the patent. If the action had been in the form of an action for infringement, he submitted with the greatest possible confidence that no variation of the position of the rheostat or its shape would have made any difference to the question of whether the arrangement was or was not an infringement. If a man could adjust his bridge, if he had the condensers in the bridge arms, if he had the condenser in the receiving circuit, it would be said that he had taken the invention. The next argument was that there was a difference between 1880 and 1876 because the reduction of resistances in the arm was so much that, in Fig. 3, the resistances were all in the rheostat. Turning to the 1876 patent, however, they found a statement that if one had condensers as bridge condensers it was found that the arms of the bridge might be greatly reduced in resistance, and a consequent reduction in the retardation of the signals effected. In other words, it pointed out in 1876 the advantages of the 1876 device. In 1880 the patentee pointed them out, and he figured them ; but they were consequences of the 1876 device. He now came to the next thing in the matter, which was the most astonishing point that he had ever heard—the left-hand arrangement, *m n* in Fig. 2 of 1876. It was only the right-hand arrangement that would enable a man to reduce or dispense with resistance. But because the patentee had made a mistake that did not prevent his having patented, and told the world of the right-hand one, and told the world that the right hand would diminish resistance. How could the other side better their case by saying that their patentee made a blunder in his earlier patent. Because he wrongly thought the left-hand method was the best, how could that affect the fact that he had taken a patent for the right-hand method, and told the world that the right-hand method did exactly what according to the 1880 patent it did do, namely, enable one to diminish resistance. He submitted that this in 1880 was identical with that of 1876, and that the American patent had lapsed.

WEDNESDAY, MARCH 7.

On the hearing of the case being resumed, Mr. A. J. WALTER argued at length the points of American law involved in the case. He contended that there was no necessity for an express declaration in America that a patent had come to an end by reason of the expiry of a similar foreign patent. By reason of the identity of the two patents and the American statute, the American patent came to an end *ipso facto* at the date of the expiration of the foreign patent. The next point was, who might be the patentee of a foreign patent, so as to bring the American patent of the same invention under the provisions of Section 4,887? "But every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent, or if there be more than one at the same time with the one having the shortest term, and in no case shall it be in force more than 17 years." There were no words limiting the foreign patent to the patent of any person. But even so, they had it on evidence from Dr. Alexander Muirhead, that he was the inventor of the 1880 patent, and they had it proved, on the face of the documents themselves, that the 1876 patent was a communication partly from abroad by Dr. Alexander Muirhead. He now came to the question which was at the root of the whole of the case. What was the degree of identity that was required according to American law between an American invention and a prior foreign invention in order to bring into operation the provisions of Section 4887? He (Counsel) held that with regard to the 1876 patent and the 1880 patent there was that degree of identity which would bring the patentee, Alexander Muirhead, within the terms of the statute and rules.

Mr. BOUSFIELD, on behalf of the plaintiffs, contended that the question was a very simple one, namely, whether the combination claimed in the 1880 patent was in substance identical with that claimed in the 1876 patent. Well, the fact was that the patentees, as regards the 1880 combination, never dreamt of it before 1880. A singular proof of this was to be found in a fact which was mentioned in the 1876 specification, Fig. 2, of which showed two arrangements, one with dotted lines and the other a full line. The dotted line arrangement was absolutely useless for the purpose of arriving at the 1880 result. That was a fact that they absolutely stated in the 1876 patent, that they preferred an arrangement which was absolutely inconsistent with getting that result which they got in the 1880 patent. Could anything show more clearly that that knowledge was not in their grasp at the time? The other side did not say the 1880 combination was in the 1876 patent absolutely upon the face of the specification. It was quite obvious that it was not there upon the face of the specification. But what they did say, was :—Yes, all the parts of it that are missing, and so on, would be inferred, because of common knowledge, and that although the inventors in 1876 had not got that combination, and did not themselves infer it from what they knew. Counsel then referred to what the United States procedure was with reference to the granting of patents. The whole American law, he said, was based upon the idea that upon the expiry of a foreign patent, the whole of what was in that foreign patent became absolutely free in America. To apply that to the particular case. Upon the expiry here of the English 1876 patent, all that was in that 1876 patent became free to the American public, and no patent could be taken out afterwards which would prevent any American citizens from using everything that was in the 1876 patent. Now a man might invent a new genus, then any species belonging to that genus was substantially the same as any other. If he invented only a new species, then no other species of that genus was substantially the same. If he invented a new variety, no other variety was substantially the same. When one had grasped the way in which the Americans decided these things, one saw how very close the identity must be in order to establish any such case before an American Court. As regards the question of the identity of a rheostat with a resistance box, of course, they were identical for some purposes. But a resistance box put into the 1880 combination would not do the same thing as the rheostat shown in the 1880 combination. That was the point. The real test was, were the American public free to do all that the 1876 patent told them to? He submitted they were absolutely free to do all that the 1876 patent told them to. They were free to make any combination of that patent, they were free to use a resistance-box in the arms of the bridge in Fig. 1 or Fig. 2, or anything else. They were free to adjust by the means shown in Figs. 4 to 14. They were free to use bridge condensers, they were free to use receiving condensers. But he submitted, by reason of the 1880 patent, which was valid, they were not free to use a combination of bridge condensers, receiving condensers, receiver cables, and rheostat, placed in that particular relation. They were not free to use that particular combination because that combination had never been disclosed before. All his side had to show was that the 1876 patent was free to the American public, and he put it that on any fair construction of the 1876 patent, every portion of it and every possible combination of it was free to the American public unless they introduce something that was not there, namely, the rheostat, and put it into that particular place with the other elements to make the 1880 patent, when, of course, they would infringe.

Mr. FINLAY then dealt with questions of law. According to his friend's contention a patentee could present the public with a needle in a haystack. He might say : "I will claim A B C D E F G and H. I claim them separately, and in all possible combinations," and, although it might take a man, as it in this case took Messrs. Muirhead, years of work to discover the one combination which would answer, one could still say : "Oh, then, that is anticipated, and because your patent of 1876 ought to have shown you, though it did not, that that was one of the many possible combinations, therefore your patent of 1880 is not for anything new, but is the same as the patent of 1876." But he (Mr. Finlay) thought he was entitled to say that the 1880 patent even stood on stronger ground than it would have stood on if it had been a mere combination of elements, all of which were to be found in the 1876 patent. It went further than that—in Fig. 3 of the 1880 patent it totally eliminated resistance. Further, not only were resistances in the arms totally eliminated from Fig. 3 of the 1880 patent, but the rheostat was introduced. The line which the defendants had taken really involved an attack on the propriety of the grant of the American patent to Mr. Alexander Muirhead. He submitted that the matter was one which should be left for the American Courts, and that the American Courts, as these cases showed, unless it was shown to them, and established by very clear evidence, that the patent of 1880 was wrongly granted, would allow it to stand. The agreement showed that what the defendants contracted was to pay the royalty for the face term of the patent, while his clients agreed for the face term of the patent to give them the benefit of any improvements.

After some further remarks from Mr. WALTER on some points of law, the hearing of the case came to an end. Judgment reserved.

Hall v. Charlesworth.

This was a motion before Mr. Vice-Chancellor Robinson, in the Lancashire Chancery Court, Manchester, for an injunction to restrain the defendant from retaining certain letters addressed to the plaintiff or taking advantage of the information contained in them. Mr. Roby, for the plaintiff, stated that some time ago the defendant, Mr. Sheard Charlesworth, carried on business at the Richmond Hill Ironworks, Oldham, as a printers' engineer. The plaintiff, Mr. Joseph Platt Hall, joined him in partnership, their joint business being that of electrical engineers, and having nothing to do with the defendant's own business of printers' engineer. In September, 1892, the style of the partnership was altered to "Charlesworth, Hall, & Co." In February of this year the partnership was dissolved. Under the partnership agreement it was provided that when notice to dissolve had been given by either party, notice was also to be given as to the price either was prepared to give for the partnership property and assets. Upon the dissolution the plaintiff sent in a notice for £2,800, and the defendant, who had offered £3,000 but withdrawn the offer by consent, accepted it. Immediately after the dissolution difficulties arose as to the letters addressed to "Charlesworth, Hall and Co.," which the plaintiff contended passed to him by virtue of his purchase.

Mr. MABERLEY, for the defendant, submitted that the purchase for £2,800 did not include the goodwill.

The VICE-CHANCELLOR granted an order restraining the defendant till the hearing of the action from retaining, opening or reading any letters, telegrams, parcels or communications addressed to the partnership firm, and from supplying any orders contained in such letters, the plaintiff to give an undertaking as to damages, to hand over to the defendant any letters intended for him personally, to preserve all letters addressed to the original firm, and to keep an account of profits obtained from orders contained in such letters

Wise v. Metropolitan Electric Supply Company (Limited).

The hearing of this action was commenced before Mr. Justice Stirling on Tuesday last. The plaintiff, who resides and conducts a business at 43, Manchester-street, Manchester-square, acting with another resident in the street, Mr. Grant, sought to obtain an injunction against the defendant Company to restrain them from continuing the nuisance arising from the noise and vibration caused by the working of the engines at their electric station in Manchester-street.

Mr. Graham Hastings, Q.C., and Mr. Beaumont appeared for the plaintiffs, and Sir Richard Webster, Q.C., Mr. Phipson Beale, Q.C., and Mr. Vernon Smith for the defendants.

Mr. GRAHAM HASTINGS, in opening, described the nature of the vibration, which he said was of a very peculiar and varying character. Sometimes the upper part of the house was affected, and at others the lower rooms. The defendants acquired their lease in 1888, and got to

Digitized by Google

work in July, 1890. The vibration had gone on increasing, and was now intolerable. Inmates of the adjoining houses had their rest broken, and suffered in health in consequence; clocks were stopped, and other annoying effects produced.

Prof. S. P. THOMPSON gave evidence of having observed vibration in different rooms in the house, both by personal sensation when sitting upon sofas and chairs, and by observation of the rattling of windows and the shaking of walls. He produced a phonograph which had been placed in the rooms for the purpose of recording the sounds produced.

On Wednesday, Mr. WISE, the plaintiff, gave evidence corroborating the opening statement of counsel, and stating that his nervous system had been greatly upset, whilst he had experienced considerable falling off in his business, and he received frequent complaints from his lodgers.

Mr. W. H. GRANT, of 17, Manchester-street, gave similar evidence, after which,

Sir RICHARD WEBSTER commenced his opening speech for the defence, relying mainly upon the conditions under which persons were entitled to acquire land for the purposes of gas and electric lighting works.

At the conclusion of the sitting the case was adjourned over the Vacation.

A full report of this case will appear in an early issue.

CORRESPONDENCE.

TESTING THE HYSTERESIS IN IRON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of March 3rd you gave Mr. Kapp's very interesting method of measuring, in workshop practice, the hysteresis in the iron plates used for transformers and armatures. As was pointed out, what is wanted is not so much absolute measures of the hysteresis as relative ones, so that the manufacturer can compare different samples of iron, and can ensure that he is getting iron of uniform quality. We have for some time past used a very simple method of comparing different samples of iron, depending on the rise of temperature of the sample when subjected to an alternating magnetic field.

Two solenoids on wood frames, and identical in every respect, are coupled in series on an alternating circuit. Into each of these a core is put, consisting of a definite weight of iron plates, insulated from one another with paper, and having in the centre a piece of wood with a slot for a thermometer; one of these cores is prepared of plates which are considered standard, and the other of the plates to be tested. Readings of the thermometers are taken at intervals, and the one which shows least rise of temperature is considered the best iron. The induction in the iron can be varied both by varying the E.M.F. on the coils, and by varying the weight and number of plates in the cores. The whole apparatus is so simple that it can be worked by an intelligent apprentice.

We may say that we have found no advantage to be gained in annealing the plates as obtained from the makers, but unless insulated from one another by some medium such as paper, the loss is largely increased.—Yours, &c.,

C. A. PARSONS AND CO.

Heaton Works, Newcastle-on-Tyne, March 12, 1894.

LOCALISING FAULTS IN STREET MAINS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Personally I have never used the test, as suggested by Mr. Collis, for localising faults in lighting mains, and concerning which he desires mental light; but the following comments upon his letter may be useful to himself and others interested in the subject.

Reference to his diagram will show that the galvanometer circuit is established through the earth and *fault*. For "dead earth" and fairly constant faults the plan should give accurate results, with rapidity of adjustment, balancing to the false zero, of course, being necessary, and care being taken to keep the compensating wire well insulated.

In the case, however, of small and varying faults it would seem open to this objection: The resistance of the fault must govern the current passing through the galvanometer, and sudden and capricious changes (so frequent) in this resistance would produce corresponding galvanometer disturbances, thus rendering it difficult practically to obtain a balance. In other words, the test would be made extremely uncertain by rapid variations in the false zero.

Mr. Collis does not state the kind of galvanometer he proposes using.

I doubt whether a needle instrument is sensitive enough. He probably would require a portable astatic, with daylight transparent scale, and no lamp. With such a galvanometer it often is possible to dispense with a battery, and localise instead with the fault current.

The higher the conductivity ratio of the compensating wire to that of the faulty main the better. The first-mentioned need be only of large enough gauge to preclude undue heating effect from the battery current.—Yours, &c.,

March 14, 1894. H. W. SULLIVAN.

THE CALCULATION OF MAINS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with great interest the leading article in your issue of February 9th. This article, and some former remarks on the same subject which appeared in your esteemed paper, have led me to suppose that the question of a more accurate calculation of mains for electric supply is beginning to meet with a marked attention in your country. As however, in your discussion of the matter, you come to the conclusion that the method of calculation, as it is used in Germany, is not much more than a pleasant pastime for mathematicians, I beg by the following lines to express my own opinion, which is somewhat different. In doing so I think I am speaking, not only in my own name, but in that of most German electricians engaged in projecting networks for electric supply.

A difference must be made between *projecting a plant*, the execution of which is not yet certain, and between *designing a network for immediate execution.* Whenever a large community wishes to have tenders for a system of electric supply it will give all firms desirous of competing the same data for the load of the network, *i.e.*, the number of lamps and their distribution among the various streets. It matters little whether these indications are exactly in harmony with the actual circumstances (such indications being altogether impossible to be made), the chief object being to offer an equal basis for the examination of all tenders received. For this reason special care must be taken in determining the sections so as not to waste copper, and to place it instead where it is more useful, in order to obtain the highest effect possible.

The estimates of the various firms are generally submitted to a jury with a view to accurately examine the density of current, drop, and balancing of tension, &c. Their opinion on these points, in connection with the estimated outlay, will be decisive for the result of the adjudication.

It is quite natural that, under such circumstances, the greatest care must be bestowed on the mathematical determination of the site for the feeding points, and of the sections generally, much more care than there would be necessary in designing a network for immediate execution. Indeed, in the latter case, it would be perfectly right to proceed in a more off-hand manner, because, as set forth in your article, the inexactitude of the elementary figures, the variability of those figures in the course of time, &c., would have to be taken into consideration.

The ability, however, of working in that off-hand manner requires some experience, which can only be obtained by a careful study of the properties of a network. The way proposed in your article, *i.e.*, to draw in more copper when the loss increases, will enable only a very limited number of people to obtain this experience, and even these only after a very long time. A much easier way is, in my opinion, to design some networks in the said off-hand manner and to *scrutinise the same afterwards by mathematical calculation* as to the distribution of current and drop, in order to determine before all the influence exercised on the distribution of the current by any modification of the sections or the load or by the junction of new conductors. Such researches are particularly interesting; they will facilitate an insight into the properties which a network has, or should have, much better than the examination of the drop of existing networks, such an examination being moreover possible only on very rare occasions.

In many German towns the networks have been calculated in this manner after laying, consequently the conducting engineer has gained a perfect knowledge of the properties of the network

Digitized by Google

under his control, as well as of its working under different loads. He is able to say whether any particular service main is capable of bearing an increase of load or not. The possibility of easily obtaining such a perfect knowledge is a further argument in favour of accurate calculations in connection with *laid networks*, and it is of special importance when special guarantees have been taken for the cable, as for instance that the load of a cable must not exceed a certain limit.

The above considerations have guided me when establishing my method of calculating systems of electrical supply, which has appeared in the *Elektrotechnische Zeitschrift*, No. 37, of September 15, 1893. It has been my ambition to form that method so as to allow the calculation to be executed in accordance with it in the easiest possible way, and—after the system has once been calculated—easily to modify the calculation according to the modifications of load and section; further, to make the calculation so lucid that the influence of the said modifications will clearly appear in the course of the calculation.

I may hope that my method will in some way form a useful contribution to the solution of the problem, as in this country the systematic calculation of mains is being carried out, not only by mathematicians, but more especially by electrical engineers engaged in practical work.—Yours, &c.,

Mülheim-am-Rhein, JOACHIM TEICHMÜLLER,
March 12, 1894. Elektro-Ingenieur.

COST OF GAS AND ELECTRIC LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I enclose some figures respecting the relative cost of gas and electricity, which seems to me of some value and interest. They are based on the figures supplied by the bursar of Hertford College, Oxford.

I may remark that in the first table the year 1892 was not available for purposes of comparison, because it was a "broken" year, electricity being employed during only a portion of it. In 1891 it was impossible to separate the cost of "heating" from that of "lighting" gas, so that the cost of "heating" gas has been included in both years' accounts.

The balance in favour of electricity might, as a matter of fact, have been considerably increased, for in 1891 the college paid a sum of £15. 1s. 8d. for lighting its dining hall with oil lamps, while the cost of lighting the dining hall by electricity is included in amount given for 1893. The total cost for 1891 would then have been £95. 7s. 4d., as against £75. 17s. 11d. in 1893, making the saving by electricity, as compared with gas and oil, £19. 9s. 5d., instead of £4. 7s. 9d. As, however, this cost of lighting the hall by oil in 1891 was obviously abnormal and due to exceptional circumstances, it seemed fairer to omit it altogether. This has been done and no allowance has been made in the ac ount for 1893, so that in these figures there is *no hypothetical element whatever*. The figures in the second table are not at all unique. I have frequently observed a saving of 40 per cent. effected by care and attention.

It appears conclusively from this, that under careful management electricity at 8d. costs less than gas at 3s. 2d., and, besides the direct saving in money, yields indirect saving in greater illumination, greater cleanliness, and greater convenience.—Yours, &c., L. A. SELBY BIGGE.

University College, Oxford, March 8, 1894.

(1) Figures showing the relative cost of gas and electric light in Hertford College:—

	£	s.	d.	£	s.	d.
1891.—Cost of gas at 2s. 8d. per 1,000 used for public lighting and heating				67	12	2
1893.—Cost of gas at 2s. 8d., 2s. 10d., and 3s. 2d. per 1,000 used for public heating ...	14	19	7	75	0	3
Cost of electricity at 8d. per unit used for public lighting	60	0	8			
NOTE.—The cost of gas consumed in 1891, if taken at the present price of 3s. 2d. would have been				80	5	8
The cost of gas consumed in 1893, if taken at the same price of 3s. 2d. for the whole year, would have been £15. 17s. 3d., making together with electricity a total cost of				75	17	11
This shows that with gas at the present price of 3s. 2d. and electricity at 8d., the positive saving in money to the college by the introduction of electricity is ...				4	7	9

(2) Figures showing the saving effected in the consumption of electric current by economy and good management:—

Consumption in "units" in — College.

		1892.		1893.		
Week ending	Nov. 1,	124·8.....	Corresponding week,	80·2......	Saving	44·6
„	„ 8,	126·8	„	58·6......	„	68·2
„	„ 15,	138·0......	„	85·0......	„	53·0
„	„ 22,	146·0	„	78·0......	„	68·0
„	„ 29,	108·0	„	72·0......	„	36·0
„	Dec. 6,	131·0......	„	72·0	„	59·0
„	„ 13,	152·0......	„	72·0......	„	80·0

Total for seven weeks in 1892, 926·6. At 8d. per unit = £30. 17s. 8d.
Total for seven corresponding weeks in 1893, 517·8 = £17. 5s. 2d.
Total saving, 408·8 = £13. 11s. 6d, or about 43 per cent.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The General Manager of the Glasgow Corporation Tramways invites offers from firms in a position to contract for the electric lighting of about 240 tramcars for one or more years. Offers to Mr. John Young, City Chambers, Glasgow.

TENDERS ACCEPTED.—The Bolton Town Council have accepted the tender of Mr. W. Pollit for the construction of four transformers in connection with their electric lighting undertaking. The Corporation have also accepted the tenders of Messrs. Crumbelhulme and Sons for 100 lamp pillars, and of Messrs. Siemens Brothers and Co. for electric mains to the Town Hall and on to Messrs. Wood's foundry. The operations at the Spa-road works are approaching completion.

———— The Yarmouth Town Council have received 26 tenders for the laying down of the electric light installation, only six of these being complete. The lowest tender is Messrs. Crompton and Co.'s, at £12,578. 4s., and the highest Mr. H. South's, £19,624. Messrs. Crompton and Co.'s tender has been accepted.

———— The tender of Messrs. Penman and Co., of Glasgow, has been accepted by the Belfast Harbour Commissioners for the supply of a Cornish boiler for the electric light station at Abercorn Basin.

BUSINESS CHANGE.—Mr. W. J. Hassard has acquired the business of optician and philosophical instrument maker lately carried on at 209, Sauchiehall-street, Glasgow, by Mr. Mathew Edwards, and since his death by the trustees.

AUCTION.—Cadby Hall, the Kensington works of Messrs. Woodhouse & Rawson, is shortly to be put up to auction by Messrs. G. A. Wilkinson & Son.

DISSOLUTIONS OF PARTNERSHIP.—Messrs. Rains, Middleton and Co., electrical engineers, Connaught Mansions, 34, Victoria-street, S.W., have dissolved partnership.

APPOINTMENT.—Mr. C. H. Wordingham has accepted the position of chief engineer to the Manchester Corporation Electric Works, at the invitation of the Electric Lighting Committee. Mr. Wordingham superintended the carrying out of the several contracts for the establishment of the central stations at Manchester and Whitehaven on behalf of Dr. Hopkinson, and has been running the Manchester station during the last three months.

PLANT FOR SALE.—Messrs. Wheatley Kirk, Price and Goulty advertise several complete electric light installations for sale, cheap. Particulars will be found in our advertisement columns.

LIQUIDATIONS.—Mr. C. J. Stewart, the official liquidator of the Medical Battery Company (Limited), gives notice that the following persons have been appointed a committee of inspection to act with him:—Messrs. L. J. Greenberg, J. H. Lile, A. L. Poulter, C. B. Harness, and Major Charles Elers.

———— A petition has been presented for the compulsory winding up of the South Staffordshire Tramways Company, and is down for hearing at the Royal Courts of Justice, Strand, W.C., on the 21st inst.

———— The Official Liquidator has issued a statement of the affairs of R. Bolton and Co. (Limited), in which he says that by an agreement dated April 22, 1893, made between Mr. Bolton as the vendor and Mr. H. Coward on behalf of the Company, it was stipulated (*inter alia*) that the Company should purchase as from January 1, 1893, the goodwill of the business and the copyrights appertaining thereto, the book debts incurred after December 31, 1892, and all patents, licences, &c., together with the interest of the vendor in a stock of carbons, &c. The purchase price was fixed at £8,000, payable in cash and shares on or before April 15, 1894. The insolvency of the Company is attributed by the secretary to depression in business owing to the low state of

Digitized by Google

the Italian and Sicilian markets, where the chief business was done, to depreciation in value of a large stock of carbons (the vendor's interest in which was taken over by the Company), and to bad debts. The statement of affairs discloses liabilities £2,259, of which £1,293 are unsecured, with assets estimated to produce £77 net, the deficiency as regards contributories being returned at £8,248.

BANKRUPTCIES.—Mr. Louis Swaby applied last week at the Brentford Bankruptcy Court, before Judge Bagshawe, for his discharge. In the affidavit filed in support of the application Mr. Swaby urged that his bankruptcy had been caused by circumstances beyond his control, and that he was unable to pay his just debts on account of the malicious persecution and fraud to which he alleged he had been subjected whilst carrying out his duties as a Director of the Maxim-Weston Electric Light Company. Mr. Swaby further states that Mr. Hugh Watt, who was on the directorate of the Maxim-Weston Company, was responsible to his estate for various sums. The Official Receiver (Mr. Mercer), however, stated that the bankrupt had contributed to his bankruptcy by rash and hazardous speculations. He (the Official Receiver) had made every attempt to collect the bankrupt's debts, but without avail. He had written to Mr. Watt, who denied all the charges preferred against him by Mr. Swaby, and the judge observed that a letter received from Mr. Watt, in reference to his alleged indebtedness to the bankrupt's estate, was a very significant commentary upon the affidavit put in. The judge held that the speculations in which the bankrupt had indulged were to an extent rash and hazardous, and he suspended the discharge for two years, to date from December last.

——— A first and final dividend of 4s. 5¼d. in the £ is announced in the bankruptcy of Harry Austin and James Myers, lately trading as Austin and Myers, electrical engineers, 7, Florence-terrace, Armley, near Leeds.

PHONOPORE COMPANY (LIMITED).—This Company have just issued a circular, calling attention to further improvements lately made in utilising existing telegraph wires, and increasing their carrying capacity. The Company claim that their instruments have received the approval of the Board of Trade, and are guaranteed to meet their requirements. The system can be seen at work at the Company's offices, Faraday House, Charing Cross-road, London, W.C., between 10 and 5, except Saturdays.

DOMESTIC ELECTRICITY.—Messrs. Crompton and Co. gave an exhibition of electrical heating and cooking appliances at the Sanitary Institute on Friday last, before the Duchess of Albany and a large company of ladies. Mr. H. J. Dowsing, who had charge of the exhibition, showed electric ovens, hot-plates, radiators, foot-warmers, &c., at work. Her Royal Highness took great interest in the apparatus, and was particularly attracted by the perfect cleanliness of the cooking arrangements, and asked questions with regard to the principles of construction. At the close of the exhibition, Her Royal Highness expressed herself delighted with what she had seen, and thanked the demonstrator for the explanations he had given as to the working of the apparatus.

ANTI-SULPHURIC ENAMEL.—Messrs. Griffiths Bros. and Co. issue a circular giving particulars of their "Anti-Sulphuric Enamel." This material, which was first prepared at the suggestion of Messrs. Crompton and Co. to meet the need of a protection for metal and woodwork from the destructive action of the fumes and spray in battery rooms, is now in use in many of the principal central stations in which accumulators are used, the reports from which are very favourable. This enamel is also found to be of use for a variety of purposes in the electrical trade. It is found to be a good insulator, and dries quickly. We learn that at Aberdeen it is used to protect the wood and metal work from the action of the acid fumes and spray of the batteries.

MAUDSLAY, SON AND FIELD (LIMITED).—This firm announce that they are now prepared to supply the "Belleville" water-tube boilers. We have received a circular, from which we find that not only are safety and rapidity of steaming claimed, but a guarantee is made in regard to steaming capacity. Five types of "Belleville" boilers are manufactured—stationary, portable, marine, auxiliary, and steam launch. The circular contains prices of both stationary and portable types, and a form of agreement setting out the conditions the Company are prepared to enter into in supplying these boilers, which have been adopted by the British, French, Russian, Greek, and Spanish navies, electric light companies, &c.

ANTWERP EXHIBITION.—The Electricity and Hydraulic Company, of Charleroi, Belgium (whose agent in this country is Mr. D. McNaughton), have secured the contract for the lighting plant for the forthcoming Exhibition at Antwerp.

NEW ELECTRIC LAUNCH.—Messrs. Paul Jones and Son, of Gourock, have just launched a new electric launch, 18ft. in length, for Baron Barreto, of Brandon Park, Suffolk. The launch was designed by Mr. Jones, jun., is constructed of light, substantial materials, and weighs less than 4cwt. The launch is to be used as a tender to the steam yacht "Asteroid."

ABERGAVENNY.—Mr. Manville has been instructed by the Improvement Commissioners to prepare a report as to the advisability of proceeding with the electric lighting scheme, and its probable cost, at a fee of £36. 15s.

ACTON.—At a meeting of the Local Board the Chairman stated that they were about to enter into an agreement with Mr. Medhurst, under which the streets of the district were to be lighted by electricity at the same rate as the Board now paid for the gas lighting.

BEDFORD.—The local electric light company have lodged with the Board of Trade their reasons for asking that department to dispense with the consent of the Bedford Urban Sanitary Authority to the Company's application for a Provisional Order. The reasons for dissenting are thirty-nine in number. Replies have also been lodged to the objections of the Urban Sanitary Authority and of Mr. W. Roff and others, and the Company submit that the objectors have shown no good or valid objections against the grant to them of a Provisional Order.

BLACKPOOL.—On Wednesday, Mr. T. Codrington held a Local Government Board inquiry on the application of the Town Council for power to borrow £24,000 for the extension of their electricity works. The Electric Lighting Committee of the Town Council have decided to accept the tender of Messrs. John Fowler and Co. (Leeds) (Limited) for the extension of the Corporation's electricity supply station, subject to the firm entering into a satisfactory contract to be prepared by the Town Clerk. The total amount of the tender is understood to be £9,000, and includes all the machinery likely to be required. Two new tramway cars are to be purchased, either with separate motor trucks or on the bogey principle, or both, at a cost of about £200 each.

BRADFORD.—It has been proposed by the Gas and Electricity Supply Committee, and adopted by the Corporation, that the charge for electric current supplied for motive power, from April 1st to October 1st, be 3½d. per unit.

BRIGHTON.—The proprietors of the Brighton and Rottingdean Seashore Electric Tramroad Company, have, in extraordinary meeting, approved the Board of Trade licence.

BROMLEY AND BECKENHAM.—The Clerk to the Beckenham Local Board has written the Bromley local authorities inviting them to appoint a small committee to consider the advisability of a joint installation of the electric light. The proposal has been referred to the Bromley Electric Lighting Committee.

BURTON.—At the last meeting of the Town Council the report of the Electric Lighting Committee was discussed, and a question was asked as to the remarks concerning the re-opening of Station-street for the laying of larger pipes. Alderman Lowe, Chairman of the committee, said the contractors, Messrs. Fowler and Hammond, included in their tender cables to be laid in cast-iron pipes of a certain size. When it was found that the tubes were not large enough, the contractors at once agreed to bear the expense involved in laying down another set of pipes and in opening and relaying the footpaths. The loss amounted to £300, and would be borne by the contractors.

BUXTON.—The Local Board have decided to apply to the Board of Trade for an Electric Lighting Provisional Order.

CANTERBURY.—An extension of time to June 30th has been granted to the Brush Company to enable them to form the Canterbury Electricity Supply Company. The Town Council have asked the Brush Company to issue a prospectus of the new company, as, until this is done, the whole matter is at a standstill.

CASTLEFORD.—A special meeting of the Local Board was held yesterday (Thursday) to consider a report from Mr. R. Hammond on the question of installing the electric light at Castleford.

CORK.—A sitting of the Judicial Committee of the Privy Council was held in Dublin last week, at which the Cork Tramways Company submitted a scheme for a system of tramways to be constructed to run through the city of Cork, with a right to use electricity as motive power. Mr. Ronan, Q.C., who appeared for the Tramways Company, said the scheme was before the Committee in 1892, and was practically passed. The Corporation of Cork were in favour of the scheme, and the Harbour Commissioners had consented to the tramway so far as it affected their interests. An objection had been taken by the Board of Trade to a portion of the route suggested to be opened, and the Lord Chancellor stated that the Committee could not make an order irrespective of this suggestion. The scheme was agreed to as submitted, excepting so far as the Board of Trade's objection, regarding which the promoters were recommended to agree with that body.

DESTRUCTIVE FIRE.—On Saturday last a fire broke out on the premises at Birkenhead occupied by the Hope-Jones Electric Organ Company. Considerable damage was done before the conflagration was subdued.

Digitized by Google

DERBY.—The opening of the new Midland Institute supplies an occasion for several of the leading provincial journals to call attention to the vastness of the Midland Company's undertaking. The capital of the Company is £100,000,000. It possesses two thousand miles of railway and a staff of 54,000 men, and the Institute itself has grown out of a small gift from the Company in 1850 to a body of earnest men employed in the locomotive department to form themselves into a reading society. The town of Derby alone contains no less than 12,000 employees of the Company. The Institute building covers an area of 960 square yards, and has been built from the designs of the Company's architect, Mr. Trubshaw. In the library two electric arc lights are used, and throughout the large hall, which is one of the finest in Derby, the advantages of the electric light are fully appreciated. The plant for lighting has been put down by the Company's electrical engineer, Mr. W. Langdon, and the light is supplied free to the Institute.

——— On Tuesday, Mr. F. H. Tullock conducted a Local Government Board inquiry regarding application from the Corporation to borrow £5,000 for electric lighting purposes. The Town Clerk explained that this £5,000 was in addition to the £30,000 already granted, and was required for new machinery and mains to be used in the extension of the lighting area.

DERRY.—The members of the Corporation inspected the generating plant at the electric light station, on Monday, previous to a test being taken of the street lamps. Amongst those present were the representatives of Messrs. Siemens Bros. and Co., Messrs. Johnson and Phillips, and Messrs. Alex. Brown and Sons. Great satisfaction was expressed at the admirable way in which the contractors had completed their tasks. The inspection was followed by speech-making, and "Success to the undertaking" was proposed by Mr. Councillor Magee, the Chairman of the Electric Lighting Committee, coupled with the names of the representatives of the contractors. A similar compliment was paid to Mr. Magee by the Mayor, who spoke in high terms of the energetic and disinterested character of Mr. Magee's laborious work in connection with their electric lighting scheme.

——— Mr. John Christie, who, as stated in our last issue, has been appointed electrician-in-charge of the Londonderry Central Station, is to receive a salary of £180 per annum.

EDINBURGH.—The Town Council have decided to charge 6d. per unit, with discounts ranging from 1 to 25 per cent. according to the amount of current consumed, the charge for electric current for motive power purposes to be 3½d. per unit. Mr. McKenzie, in proposing the above recommendations of the Lord Provost's Committee, entered fully into the financial aspect of the electric lighting question, and in the course of his remarks referred to the series of articles recently published in *The Electrician* on the relative cost of electric light and gas. In proposing a further recommendation of the Committee, for the appointment of Mr. E. W. Monkhouse as resident electrical engineer at a salary of £300 per annum (not £180 as mentioned in our last issue) it was stated that Mr. Monkhouse had the largest experience of all the 98 applicants in the kind of work which would have to be done in Edinburgh.

EXHIBITION.—An Art and Industrial Competitive Exhibition was held at Hebden Bridge on the 3rd and 5th inst., which was illuminated by the electric light, under the supervision of Mr. R. S. Blackburn. As usual the electric cooking display proved a great attraction, as did also the motive-power installation used in driving sewing machines, fans for ventilating, knife cleaners, coffee grinders, and other domestic apparatus.

FOLKESTONE.—It is evidently the intention of many of the members of the Town Council that the electric lighting question shall not have a patient hearing. The Electric Lighting Committee have obtained a supplementary report, but its discussion has been adjourned for another fortnight.

GREAT YARMOUTH.—In reference to the tenders received for the electric lighting scheme the Surveyor, at the last meeting of the Town Council, pointed out that the cost of the installation would be, according to the tenders accepted, £16,200, whilst the loan sanctioned by the Local Government Board was only for £15,000. The Council resolved to apply for sanction to borrow a further £1,500.

HALIFAX.—Notwithstanding the many improvements introduced into this town during the past 20 years, including electric lighting, the rates stand at only one halfpenny in the £ excess over those of 1873.

HAWICK.—A proposal is before the Town Council that the electric light be introduced into this town.

HENLEY-ON-THAMES.—The new launch-charging station built by Mr. Weyman for the Upper Thames Electric Launch Company on Rod Eyott is nearly completed, and the barge used for this purpose last season is to be removed.

LONDON COUNTY COUNCIL.—By 37 votes against 10 the report of the Highways Committee, embodying a proposal for placing electric light pillars in the centre of the carriageway of the Victoria Embankment, has been rejected.

LOWESTOFT.—The Town Council have instructed their surveyor to make inquiries regarding the difference in cost of lighting by gas and electricity. It is probable that the Council may consider the adoption of the electric light at an early meeting.

MANCHESTER.—The telephone question which has dragge itsd slow length along and proved a source of much concern to the local authorities, has at last been settled. The report of the Paving and Sewering Committee, which recommends that the proposals made by the National Telephone Company should be accepted, have been adopted. The overhead wires are to be taken down and placed under the streets. The annual subscription to subscribers to the National Company's system in Manchester is to remain at £10 per annum. In proposing the adoption of the Committee's report, Mr. Alderman Milling stated that in Paris the annual charge to subscribers was £16, in Lyons £12, in Madrid and Barcelona £11 17s., in St. Petersburg and Moscow £39 11s., in New York £50, in Boston £37, and in Philadelphia £25. The recommendation of Mr. Alderman Leach that the Corporation should open the streets and put down the pipes to carry the underground wires, and to hire the same to the National Company, was rejected. Several speakers urged that the suburban residents should be included in the £10 rate, and it was pointed out by the Lord Mayor that something in this direction would doubtless be conceded by the Company.——We learn that the Athenæum officials are considering the advisability of adopting the electric light throughout the building, and have commissioned Mr. S. V. Cirehugh to prepare plans and specifications for the necessary work.

MONTROSE.—Two or three members of the Police Commission propose visiting the metropolis shortly, in connection with the suggested electric lighting scheme.

OLDHAM.—The Electric Lighting Committee of the Town Council announced at their last meeting that the electric current was to be turned on yesterday (Thursday).

SALFORD.—The Gas Engineer's report to the Town Council announces that the whole of the contracts for the electric lighting works, amounting to £25,500, have been let, three of them to local firms.

STAFFORD.—The Town Council have received a communication from the Local Government Board, giving sanction to the borrowing of £20,000 for electric lighting purposes for a term of 25 years. Tenders have been invited for the erection of the necessary buildings, and the Lighting Committee have decided to obtain engines, boilers, and dynamos from certain well-known and established firms, whose names have been submitted to the Committee by Mr. J. F. Bell, the Corporation's engineer. This course was adopted in preference to advertising, because the Committee "felt it was important that the work should be done well."

STIRLING.—The members of the Corporation continue divided in opinion as to whether the Corporation should itself apply for a Provisional Order or permit the Caledonian Electric Supply Company to proceed with its application. As matters stand at present, the Board of Trade have notified the Corporation that, before taking into consideration the objections of the Corporation to the grant of the Provisional Order to the Caledonian Company, it is important that a notification should be made as to the intentions of the Corporation on the question. On Monday, at a special meeting of the Town Council, called to determine whether the Corporation should apply forthwith for a Provisional Order (after hearing an influential deputation in favour of this course being adopted), an amendment was proposed, and, on a division, was carried by a majority of ten to eight. This latest decision annuls the previous resolution of the Council to apply for a Provisional Order, and makes confusion worse confounded.

SWANSEA.—The parish church is to be lighted temporarily by electricity, through the munificence of a firm of purveyors of children's games and exercises. An attempt to use lamps bearing the legend "Studt and Son," the name of the aforesaid purveyors, was speedily "spotted," and the bulbs were substituted for others minus the advertisement.

TAUNTON.—The Electric Lighting Committee report to the Town Council that the work in connection with the electric lighting extensions is progressing favourably. A sum of £5. 5s. was voted to purchase a present for Mr. J. A. Robinson, of the Great Western Railway, whose assistance and advice has been of great value to the Committee during a period of difficulty and anxiety.

TIVERTON.—At the last meeting of the Town Council the report of the Electric Lighting Committee was referred back, with a view to considering a cheaper scheme for adoption in the borough, having regard to the proposed closing of the gas works.

WOLVERHAMPTON.—The Local Government Board have sanctioned the application of the Town Council for borrowing powers for £30,000 for their electric lighting scheme.

COMPANIES' MEETINGS AND REPORTS.

Oriental Telephone and Electric Company (Limited).

An extraordinary general meeting of the shareholders of this Company took place on Monday at the Cannon-street Hotel, to consider the confirmation of the resolutions passed at the meeting on the 21st ult., expressing the desirability of winding up the Company voluntarily with a view to its reconstruction, appointing Mr. Henry Grewing and Mr. George Bland Frost liquidators; and incorporating a new company with the same name, with a nominal capital of £200,000, in shares of £1 each, the consideration for the transfer of the assets of this Company to the new company to be the allotment to the liquidators, or as they might direct, of 171,497 fully-paid shares of the new Company. The chair was taken by Mr. William Addison.

The SECRETARY (Mr. Alex. Chalmers) read the notice convening the meeting.

The CHAIRMAN then said: Gentlemen, we are met to confirm the resolutions passed by the meeting on the 21st ultimo, but before proposing that they be confirmed I should like to say a few words. In the circular sent out by the Board on February 9th it was stated that the Directors hoped the reconstruction would be carried out before the ordinary general meeting of the Company, when a dividend for the past year would be declared. It was pointed out by a shareholder that this statement of the Board was somewhat inaccurate, as the Company would be in liquidation whenever the resolutions were confirmed, and, therefore, the Company could not pay a dividend. This was no doubt technically correct, but you will have a dividend, or, at any rate, a distribution, whichever you like to call it. The Directors have been advised by the Company's auditors that the new Company can only earn a dividend as from the period of registration, consequently the dividend the shareholders will receive next year would only be from the profits of the Company for say some 9¼ months. We, therefore, propose that the distribution which the liquidators will make to you as soon as they possibly can will be for the period from the January 1, 1893, to March 12, 1894, *i.e.*, for 14½ months. This distribution will be made on the whole of the paid up capital of the Company, this being a part of the agreement of the scheme we are now carrying out. It will be equivalent, as nearly as possible, to 4¼ per cent. per annum from January 1, 1893, to March 12, 1894, on the amount of the reduced capital, and be free of income tax. Nothwithstanding that the Vendor shares participate in the dividend, the holders of Ordinary shares of 11s. will receive a slightly improved dividend on that paid last year. You will shortly, therefore, receive from the liquidators a letter stating that on your returning your old certificates to be exchanged for new ones you will receive a cheque for the amount of your respective distributions.

The SOLICITOR (Mr. Joseph Addison) said that if the shareholders had no objection the resolutions would be moved *en bloc*, to save time.

The CHAIRMAN then proposed, and Mr. GREWING seconded, the confirmation of the resolutions.

Mr. NORRIS asked whether the statement now made that the dividend was to be paid to the Vendor shareholders was not a distinct breach of the the arrangement put forward by the Directors.

The SOLICITOR replied in the negative, adding that the scheme as they understood it was this—that the Ordinary shareholders and the Vendor shareholders, as from December 31, 1892, would participate in a certain way.

Mr. NORRIS said that he distinctly understood from the remarks made at the previous meeting, and from the wording of the report, that there was no intention for the year 1893 to distribute any dividend to the holders of the Vendor shares.

The CHAIRMAN: That was never the idea of the Board at all in the arrangement with the Vendors; it was intended that the Vendor shares should come in now.

Mr. NORRIS: But not for the past year.

The CHAIRMAN: Yes, for the past year.

The motion was then put and declared carried, and the meeting closed with the usual complimentary vote.

Oxford Electric Company (Limited).

The third ordinary general meeting of this Company was held at the offices, 45, Broad-street, Oxford, on Saturday last, under the presidency of Sir Henry Mance, C.I.E.

The CHAIRMAN said it had been extremely satisfactory to the Directors that, in consequence of a general settlement with the contractors, they had been able to open the accounts of 1893 without bringing forward the adverse balance which appeared in the balance-sheet for the preceding year. As he was Chairman of the Construction Company when the contract was entered into, he was well qualified to speak as to the intentions of the contracting parties, and he took that opportunity of expressing the Directors, entire satisfaction with the manner in which the contractors had carried out the work and fulfilled their obligations towards them. With regard to the accounts generally, he had some doubt whether the expenditure on College installations should properly be included in the capital account. In these matters, however, they were entirely in the hands of the auditors, and practically it made little difference whether it was shown in the capital account or balance-sheet. He wished them, however, to understand that this sum had been expended in fitting up certain colleges with the necessary installation in order to enable the Company to supply the light, all expenditure of this kind being guaranteed by the college authorities. If necessary, we are able to borrow what money we require for this purpose, and we receive interest from the colleges sufficient to pay the interest on the loans. The colleges have the option of purchasing the installations at any time they please, and are bound to purchase eventually at the original price. Since January 1st about £800 of this sum had been paid off. They have still a small amount of Debenture capital unissued, but this would probably be required for various extensions which were contemplated during the year, and when they required funds he had no doubt they would be able to issue the debentures at par without difficulty. Considering the short time the Company has been in operation he thought the revenue account should be regarded as extremely satisfactory. They had written off nothing for depreciation, but on the other hand, there was an item of £396 for the maintenance of machinery and plant. The proper policy was to keep the plant in thorough working order, and, with the exception of the batteries, their plant was in better order now than when it was first laid down. The cost of new battery plates would be included under the expenditure for maintenance, and proper provision made for the renewal of worn-out machinery. With regard to the £546 profit on installations and other work, the Company had carried out some important installations during the year, and also derived a reasonable profit on the sale of lamps and other articles. The balance at their banker's was very satisfactory for so young a company; and the stock on hand, represented by meters, service boxes, cable, coals, &c., would all be useful to them. After providing for debenture interest, there remains a balance to the credit of the net revenue account of £68. 8s. 5d., which had been carried forward. The number of 8-c.p. lamps connected to the system had increased from 4,040 to 7,012 on December 31, 1893. The number of consumers has increased from 65 to 100, colleges being counted as one only, unless there are separate installations within the same college. Amongst their customers were 10 colleges, 51 shops, five hotels, six clubs, and 15 private houses, the remainder consisting of the theatre, a church, and various offices. We are steadily adding to the number of our customers, and the following university buildings were now considering the advisability of installing the light: Magdalen Schools, Wadham, Exeter College, and the University Galleries. Trinity College was expected to make a large extension of their light almost immediately. Should all these be connected to the system it would probably mean the equivalent of an additional 1,500 8-c.p. lamps. Another 1,500 might be reckoned from other quarters, and as they had at the present moment about 7,500, at least 10,000 lamps would be installed before the end of 1894. Their length of trenching had increased from 6,500 to 7,490 yards, and low-tension supply mains from 12,000 to 13,980 yards; 1,025 yards of iron piping had been put down, and the lengths of high tension mains had been increased from 10,500 to 12,700 yards. Two new sub-stations have been established, and one transferred; 103,000 Board of Trade units were supplied to customers during the year, our best week's revenue being £144, as compared with £86 during 1892. Eighteen per cent. of the current sent out to customers has been supplied from the batteries while the machinery has been at rest. The use of a small bank of storage cells had enabled them to dispense with one shift of men, and rendered it unnecessary to move the machinery before the hour when a remunerative load might be expected. The careful record which had been kept, and the experience of the past twelve months, enabled them to estimate with accuracy when it was necessary to set in operation the tranformers at the different sub-stations. They proposed still further extending the mains almost immediately, and a further extension, to embrace the residential district in the north of Oxford, is receiving serious consideration. Throughout the year there had been a complete absence of any accident, and they had been able to keep up the constant pressure in the mains which is required by the Board of Trade. The cost of the production of the current at the works came out rather less than 4d. With regard to the efficiency of the system, it worked out at about 62 per cent., and compared favourably with other systems.

Mr. L. A. SELBY BIGGE seconded the motion for the adoption of the report (given below). He said that the results shown by some of the Oxford College accounts as to the cost of electric lighting are remarkable. The Bursar of Hertford had favoured him with the lighting accounts of his College for this last year, and assured him that the cost of electricity as used in the College in 1893 was actually less than the cost of gas used in the College in 1891; and these calculations made no allowance for the price of gas in 1893 having increased. The result was that the public lights of this College when supplied with electricity at 8d. per unit was less than when supplied with gas at 2s. 8d. per 1,000.

The report and accounts were adopted unanimously.

The CHAIRMAN proposed that Mr. Robert Buckell and Mr. John Irving Courtenay be re-elected Directors, which was seconded by Mr. GARCKE, and carried unanimously.

Mr. Carver was re-appointed auditor, and a vote of thanks to the Chairman terminated the meeting.

The following is the report of the Directors referred to:—

The Revenue Account shows a gross profit of £1,105. 7s., and after providing for the full interest on the Debentures issued up to December 31, 1893, there remains a balance of £63. 8s. 5d., which the Directors recommend should be carried forward to next account. The balance of £612. 9s. 1d. appearing to the debit of the profit and loss account, 1892, has not been brought forward into the account for the past year, as the contractors under a general settlement with the Company have refunded an amount which the Directors have applied to cancelling the preliminary expenses and the balance to debit of the revenue account referred to. During the past year the running of the plant has continued to give entire satisfaction. About

Digitized by Google

3.000 8-c.p. lamps have been added to the system, and the Directors have every reason to hope that the progress during the present year will not be less satisfactory. Since the last report extensions have been made to King Edward's-street, Holywell-street, Mansfield-road, St. Giles', St. Aldate's, and Magdalen College. The total number of lamps installed on December 31st was equivalent to 7,012 8-c.p. lamps. Ten colleges are now connected to the system, and others are expected to instal the light during the present year; 103,895 Board of Trade units were delivered to customers during 1893. The expenditure of coal per unit delivered and metered has been 0·718 of a penny, which compares favourably with the results obtained by the majority of central supply stations.

Cambridge Electric Supply Company (Limited).

The annual meeting of this Company was held at the offices, 2, Sidney-street, Cambridge, on the 6th inst., the Rev. G. B. Finch presiding.

The CHAIRMAN, in moving the adoption of the report (which appeared in our issue of the 2nd inst.), said he thought they might say that the anticipations which they all had at the outset had been even more than realised by the success of the Company. The statement in the second paragraph of the report was certainly very satisfactory to the town. They had had applications for many more lamps, and the work of extension showed no signs of being arrested. The Colleges were beginning to take the light for the rooms of the undergraduates. There was a feature in the report which they ought not to pass over, and that was with regard to carrying all receipts and expenditure under the head of profit and loss up to June 30th to capital account. The Directors thought it would be much better to treat all receipts and expenditure as belonging to the capital account up to a certain date. They hoped that the shareholders would agree with the course adopted. They all knew that in the summer months they could not carry on the concern so as to make a profit, and that was the experience of all companies at the beginning. During the summer months at Newcastle the losses had been gradually dwindling down until at last there was no loss whatever; they were so situated that they made a profit all the year round, and this they anticipated would be the case at Cambridge. From October 1st to February 20th last the Company made a profit of £768. The coal strike imposed a burden of £50 a month upon them, or they would have had a profit of £9:8 in the five months. The shareholders would notice an item in the balance-sheet, "Debentures, £7,000 at 5 per cent." This was a sum borrowed from Fosters' bank, which held a charge over the Company's property. It should properly be described as a debt owing to Fosters'. What the Directors desired to do now was to raise a sum not exceeding £10,000 on Debentures of 4½ per cent., and offer these to the members of the Company in the first instance on terms to be afterwards arranged. The Directors hoped this money would come from the shareholders in preference to any persons outside.

Sir BENJAMIN BROWNE, in seconding the adoption of the report, said he believed they had come to the point of the Company when probably it was going to be a source of more material profit than it had been in times past. He believed the Company had now arrived at a satisfactory point. They were preparing to make extensions in various directions. He was told that an extension to Newnham would probably be profitable. The question of introducing the electric light into the lodging houses, which of course was a very large item in any calculations in Cambridge, was under consideration, and a great many places of business seemed to be favourably considering the advisability of taking the light. All these extensions were very satisfactory, but they required more capital. There was no more satisfactory way of obtaining capital than by people taking up Ordinary shares; that was what identified the people with the town, and it showed confidence in the Company. At Newcastle, of which they had so often heard, they found now if they wanted another £5,000 or £10,000 for the ordinary purpose of extending their mains they had only to hold their finger up and it would come in. When he compared Newcastle with Cambridge, it seemed to him that on the whole the Cambridge Company's prospects were better.

In answer to several questions,

The Hon. C. A. PARSONS explained that the expenditure had been kept down to the very lowest figure. A large number of new lamps were coming on, and they hoped to run during next summer without any loss at all in the working expenses. They had laid 18½ miles of single cable, and 5½ miles of piping.

Mr. STURTON thought that £7,000 ought to be borrowed at 4 per cent.

The CHAIRMAN: These terms were insisted upon. We could get it when we liked. If the shareholders take up the debentures, the amount of interest will not so much matter.

Mr. YOUNG: What form of security do Messrs. Fosters' hold?

The CHAIRMAN: A debenture mortgage.

The report was adopted, and Mr. J. B. Simpson, Dr. P. W. Latham, and Mr. W. C. Hall were elected as Directors, and Mr. Arthur Rutter was re-elected auditor.

An honorarium of £150 was, after some considerable opposition, voted to the Directors for past services, and the meeting terminated with a vote of thanks to the Chairman, who retires from the Board.

Hove Electric Lighting Company (Limited).

The second annual general meeting of this Company was held on Wednesday at the Town Hall, Hove, Col. H. Woods, C.B., the Vice-Chairman of the Board of Directors, presiding.

The CHAIRMAN, in moving the adoption of the report (which appeared in our last issue), said he had to regret the absence of the Chairman of the Directors, who had had to go to India and would not return till next month. He had the pleasure of congratulating the shareholders on the continued satisfactory progress of the Company. As they would have seen from the report, the number of lights connected continued to increase, and it was expected that before the end of the current year the number of lights would be more than double the number on December 31st last, and that they would then have 14,000 or 15,000 connected up. The exact number now was 12,600. When it was considered that the actual expenditure of the Company would probably at that time not exceed £35,000 or £40,000, it must, he thought, be admitted that, compared with what was done by many other companies, this was extremely satisfactory. In addition to the private lights, it was hoped that before the end of the year the Hove Commissioners would put up some public lamps along the Front, if not in some of the streets, and this would add materially to the business of the Company, and be an advantage to the public in Hove. The success of the Company was far in excess of what was anticipated, and the shares were consequently a good investment. But to ensure the continued success of the Company, and to enable them to meet the calls upon them by intending consumers, further capital was required. Hitherto their contractors, Messrs. Crompton and Co., had promptly executed all orders, and had met the Directors in every way, but considerable extension was necessary on such a scale that it would not be prudent for the Directors to enter into any fresh contracts unless further capital was subscribed. There was another matter upon which the Directors were able to congratulate the shareholders—the retirement of the opposition Company from the field, thus giving this Company the monopoly. Dealing with the present condition of affairs, the Chairman said the Directors proposed to offer the balance of the shares to the public, and at the same time issue a debenture prospectus. The shareholders would be asked to empower the Directors to issue more debentures than by the Articles of Association they had now the power to do; but it was not intended to make a higher issue than £12,500 for the present, though it was proposed that this sum should form part of a total of £25,000 when the magnitude of the works justified the Directors in making such an issue. He concluded by proposing the adoption of the report

Mr. C. F. TUFNELL seconded the motion.

In reply to remarks by Mr J. CASH, who questioned the wisdom of the Directors in laying mains outside the compulsory area, the CHAIRMAN said that there were already a large number of lights supplied by these mains, which had been laid with regard to future development, after advice from certain inhabitants and from the engineer of the Company.

Mr. J. F. ALBRIGHT congratulated the Directors upon the report they had submitted. He was himself a Director of several important electric lighting companies, some larger and some smaller than this, and he claimed to be able to judge as to how a company was being managed and of the progress it was making; and he considered the prospects of this Company, in which he was largely interested, were exceptionally good. The Company was in possession of a contract with the Hove Commissioners, which was equivalent to a Provisional Order, and a Provisional Order was considered a valuable property. They were also in possession of an extremely good district for electric lighting, and, most important of all, they were in possession of an assured consumption for their electric current, which would give them all the work they could do for several years to come. Other companies started with the probability of getting into such a position after two, three, or four years' working, but this Company had started at that point, and the result was that after carrying on their business for twelve months they showed a profit of £1. Moreover, he had got to study every item of the expenditure of the electric lighting companies with which he was connected, and he could assure the shareholders of this Company that it was worked at an extremely low cost, bearing in mind that the work was carried out under difficulties as to plant, and as compared with companies which had been established with more permanent plant from the commencement. It was, he reminded the shareholders, to their interest to support the Directors in the matter of capital.

Mr. G. B. WOODRUFF having also expressed his satisfaction at the prospects of the Company, the motion was carried.

On the motion of Mr. TUFNELL, seconded by Mr. ALBRIGHT, Colonel A. J. Filgate, R.E., and Colonel H. Wood, C.B., the retiring Directors, were re-elected; and Mr. Robert Payne, F.C.A., was re-elected auditor.

The CHAIRMAN then proposed—

"*That the Directors be and they are hereby empowered to borrow or raise any sum or sums of money on such security and upon such terms as to interest or otherwise as they may deem fit, and for the purposes of securing the same and interest, or for any other purposes, may create, issue, make, and give respectively perpetual or redeemable Debentures or Debenture stock, or any mortgage or charge upon the undertaking, or the whole or any part of the property, present or future, or uncalled capital of the Company, provided that they shall not, without the further sanction of a general meeting of the Company, borrow or raise any sum of money exceeding in the whole £25,000.*"

He said it was necessary for carrying on the business of the Company that they should have more money. They had authority to raise by debentures £10,000, but unless the shares were taken up, as they hoped they would be, they found they would have to expend £12,500. That was the extent to which they proposed to go for the present, and the remaining sum would be required only by the enlarging of their business.

Mr. TUFNELL seconded, and the SECRETARY having explained that it was necessary for the shareholders to agree to this resolution before the Directors could raise more than £10,000 by debentures, and that this total sum of £25,000 would include this £10,000, the motion was agreed to.

A vote of thanks to the Directors for their services during the past year terminated the proceedings.

Digitized by Google

Birmingham Electric Supply Company (Limited).

The fourth annual meeting of this Company was held on the 8th inst., at the offices, Dale End, Mr. Henry Buckley presiding. In moving the adoption of the report, the CHAIRMAN said he considered the progress made by the Company was satisfactory. On December 31, 1892, the total number of 16-c.p. lamps, or their equivalent, on order was 8,329, and on the same date in 1893 the number was 10,223. Since then there had been a still further increase, and the number was now more than 11,200. The consumers in the same time had increased from 223 to upwards of 300, and the current, measured by units, 214,088 to 352,096. The percentage of increase had been : in lamps, 22·7 ; in consumers, 30·3 ; and in current, 64·5. The lamp patents had expired, and they could now supply a good article at 10s. per dozen, whereas twelve months ago they cost 3s. 9d. each. Additions had been made to the supply mains. He reminded those present that at the last annual meeting he referred to the question of new areas ; but in deference to the wishes of the City Council the matter was deferred for a time. The subject was brought before the Council in July last, and as the result of what then took place the usual Parliamentary notices had been given, and by the autumn the Directors hoped to be possessed of powers to extend their system to the districts named. In consequence of those extensions, additions to their plant would have to be made, and it was probable that the Directors would call up another £1 per share.

The report was carried, and a dividend of 4 per cent. was declared, which will absorb £2,715. 6s. 7d. ; £1,872. 18s. 1d. was carried to the credit of the depreciation reserve fund, and a further sum of £250 was placed to the general reserve fund, leaving a balance of £409. 12s. to be carried to next year's account.

Messrs. H. Buckley and J. F. Albright were re-elected Directors, and Messrs. Sharp, Parsons and Co. auditors.

Elmore's German and Austro-Hungarian Metal Company (Limited).

An extraordinary general meeting of this Company was held on Monday, at Winchester House, E.C., under the presidency of Mr. John MacFarlan.

The CHAIRMAN said : We meet you to-day with greater pleasure than in May last year, for now we are able to report to you a far better state of things than existed at that date, and that the working of the Company is unquestionably now a success. During the past ten months the Company has been passing through a most trying time, owing to the want of the necessary capital, and it has only been by the Directors personally assisting the Company to a considerable amount that they have been able to prevent it going into liquidation, and to-day they look with confidence to a speedy reward for the troubles and trials of the past. We have received a German Government contract for the supply of all copper tubes between 7in. and 12in. in diameter that will be required by the docks at Kiel, Wilhelmshaven, and Dantzig for the next three years, and believe we could obtain even larger orders from them if we were in a position to execute them. This means that our goods have been thoroughly tested by the Government, and have not been found wanting, and that we have obtained preference over all other copper manufacturers, and when we consider the short period that our factory has been in existence your Directors think there is cause for congratulation. We have not only received this particular contract, but have had many others offered. On the formation of the Company the Directors were informed, and believed, that £50,000 would be ample. We have however, never received the whole of this amount, but only about £45,000. At the commencement of the present year £5,000 Debenture stock was subscribed for, but we have not yet got the whole of this money paid up. On November 4th last the final instalment upon the property fell due, and although we had tried every possible means in our power to raise money in Germany, we had not been able to do it The vendor became very pressing, and eventually commenced proceedings against us with a view of seizing the property and putting it up for auction. This would, of course, have been simply fatal to us, and it would have had almost the same effect had the sale been even advertised. Finding our efforts to obtain money unavailing, the secretary saw Mr. Berger (the vendor) several times, who ultimately agreed that if the sum of £3,000 was paid him on February 1st he would allow the balance to stand over for two years. At this time we were refusing large orders at the factory owing to the want of copper, additional machinery, &c., which we were unable to purchase owing to the want of the necessary capital. The Directors are aware that the issue of Preference shares is a very stringent measure to adopt, but they believe it to be the only feasible method of saving the Company and of averting heavy loss to the shareholders. The Preference shares now to be issued are of £2 each, and will be allotted to the shareholders at the rate of one share for every five Ordinary shares, which is equal to a call of 8s. per Ordinary share. It is proposed that only 15,000 of these shares shall be allotted ; this should give us £30,000. Nearly the whole of this capital will be expended upon the factory and in copper, and in paying the £3,000 already mentioned. Therefore, this issue is not so severe after all, and in order to enable every shareholder to take up his proportion we shall extend the time for payment until January, 1895, and, as the calls are for but small amounts, I feel confident that it will be in the power of every shareholder to subscribe. The Directors are in every way satisfied with the work that has been done and the prospects of the Company, should the capital we ask for be subscribed. We have worked for the last eighteen months without fees, although the business has been of the most harassing nature. Had it not been for the way in which we have been supported by Mr. Ellis (the secretary) and Mr. Preschlin (the works manager) it would have been quite impossible to have carried on the business of the Company.

The CHAIRMAN then moved a resolution approving the issue of Preference shares, which was seconded by General Fraser.

Shareholders asked various questions as to the amount of business and profits made ; whether the plant was fully utilised ; how much capital had been raised ; and whether the Directors had any guarantee that this issue of Preference shares would be taken up ; to which the Chairman said their position was that they required £5,000 within a fortnight, and they therefore asked shareholders to adopt the proposal for the issue of Preference shares. It would only be put in force as a last resort, and failing any better scheme being proposed. They had a guarantee that the Preference shares would be taken up.

Mr. F. L. RAWSON also spoke, urging an alternative scheme which had been advocated by Mr. W. Elmore, who was unable to be present. He urged the shareholders not to agree to any such sacrifice of their interests as that indicated by the proposed issue of Preference shares taking 90 per cent. of the profits. In his opinion the German Company should be in a far better position than any other Elmore Company, because of its splendid water power, which, necessarily, saves so very large a proportion of the cost of manufacture ; and, secondly, on account of the high protective tariff in Germany, where the Company's productions have to be sold. They could produce tubes and other copper goods of a quality infinitely superior to the products of their competitors, as was proved by the large and profitable orders offered to the works. He suggested that the required capital could be provided by an issue of £30,000 in Ten per Cent. Preference shares in the Elmore's German Metall Actien-Gesellschaft. These should be cumulative, and be preferential in both capital and dividend, and after the 10 per cent. they should rank as to 25 per cent. of all that remains, the other 75 per cent. of the profits going to the other shares. Banking arrangements should then be made for an overdraft with which to purchase raw copper, such as had recently been negotiated for the English and Wire Companies at Leeds. As the issue would be upon the Elmore's German Metall Actien Gesellschaft, and not upon the Elmore's German and Austro-Hungarian Company, it would be free from the numerous complications of the various issues of debentures in the latter Company, and an investor will be able to see his position quite clearly.

The CHAIRMAN, in referring to Mr. Elmore's proposal, said that the fact of their having secured the German Government contract necessitated their having command of a considerable sum of money, for they would be required to turn out up to 15 tons per week. If they were placed in the possession of £5,000 within the next fortnight, to meet the more pressing liabilities, they were content to agree to Mr. Elmore's scheme, which would, however, have to be carried through within the next two months.

Ultimately the Directors' proposals were agreed to.

Direct Spanish Telegraph Company (Limited).

The following report of the Directors of this Company for the half-year ended December 31st last is to be presented at the general meeting of shareholders, to be held on Tuesday next, at Winchester House, E.C., at 1:45 p.m. :—

The accounts for the half-year show, after providing for debenture interest, a balance to the credit of profit and loss of £4,996. 7s. 1d. The traffic receipts show a decrease of £509. 15s. 4d., as compared with the corresponding period of 1892. This falling off in the receipts is entirely owing to the general depression of trade during the half-year. The working expenses are £35. 18s. 6d. less than those for the corresponding period of last year.

After adding the usual sum of £2,500 to the reserve fund, the balance of profit and loss amounts to £2,496. 7s. 1d. Out of this amount the Directors recommend the payment of the dividend at the rate of 10 per cent. per annum on the Preference shares, and a dividend at the rate of 4 per cent. per annum (free of income-tax) on the Ordinary shares, and to carry forward the balance. The reserve fund will then amount to £37,551. 11s. 10d.

The Company's cables, and the land lines in connection with them, have with one exception continued in good working order throughout the half-year. The Falmouth-Bilbao cable became interrupted on August 16, 1893; it was, however, promptly and effectually repaired on August 24th by the Eastern Telegraph Company's cable ship "Electra." The cost of these repairs, amounting to £1,453. 18s. 9d., has been taken from the reserve fund, and it is intended to repay this amount to that fund out of future profits.

A branch telegraph office of the Company was opened on November 6, 1893, in the Foreign Auction Hall, Covent-garden Market, where a great portion of the fruit trade with Spain is carried on. The results are satisfactory.

Sir John Pender, G.C.M.G., M.P., and Mr. Etlinger are the Directors retiring by rotation, and offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths and Co. also offer themselves for re-election.

W. T. Henley's Telegraph Works Company (Limited).

The following is the report of the Directors of this Company for the year 1893, to be presented at the ordinary general meeting to be held at the Company's Offices, 27, Martin's-lane, Cannon-street, London, E.C., on Thursday next, at 2.30 p.m. :—

The accounts show that a net profit has been made of £10,777. 6s. 2d. After payment of interest and income-tax, and making allowance for depreciation of plant, there remains £7,256. 14s. 1d., to which must be added £13,399. 10s. 1d. brought forward from last year. Deducting £1,050, the half-year's dividend on Preference shares paid in October last, there remains a disposal balance of £19,606. 4s. 2d. The Directors have added £10,000 to the Reserve Fund, and they propose the payment of a further half-year's dividend on the Preference shares at the rate of 7 per cent. per annum, and a dividend for the year at the rate of 5 per cent. free of income-tax on the Ordinary shares ; these payments together absorb £4,468. 10s., and leave a balance of £5,137. 14s. 2d. to be carried forward.

Digitized by Google

A further sum of £4,000 has been paid off the £30,000 B Debentures created in 1891, which has reduced their amount to £12,000.

The improvements and extension of the Company's factories at North Woolwich, which were contemplated when the Preference capital was subscribed, have been completed, and the buildings, machinery, tools, &c., of the Company are now in first-class condition. The general business of the Company has been satisfactory, and a few hundreds of miles of submarine cables have been manufactured for various telegraph companies and for the British Government.

The Directors who retire are Mr. Frederick Newton and General George Hutchinson, C.B., C.S.I., who offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

ELECTRICITY USERS' ASSOCIATION (LIMITED).—This Company was registered on March 9th, with a capital of £2,000, in £1 shares, to insure against all kinds of accidents to electrical apparatus generally; to replace broken or worn out parts, lamps, &c., with new; to make all necessary repairs and keep up installations to as high a standard of efficiency under competent inspection as is possible: to provide for competent inspection of engines, boilers, pumps, all running machinery, accumulators, switches, mains, meters, and other apparatus connected with the supply of electric light, heat or power; and to advise generally upon specifications and estimates for the erection of electric lighting or other installations. The subscribers (with one share each) are Arthur E. Samuell, W. T. Lawrence, J. W. Winch, G. H. Smith, R. H. Behrend, G. Earle, and W. H. Page. The first Directors are to be nominated by the signatories to the Memorandum of Association.

ORIENTAL TELEPHONE AND ELECTRIC LIGHT COMPANY (LIMITED).—This Company was registered on March 12th, with a capital of £200,000, in £1 shares, to acquire and take over as a going concern the undertaking, assets, property, and effects of the Oriental Telephone and Electric Company (Limited), now in liquidation, upon the terms set forth in the special resolutions of the old Company, passed February 21, 1894, and confirmed March 12, 1894, to acquire any letters patent, rights, privileges, concessions, or monopolies for the use, sale, working, or manufacture, or otherwise, relating to any telephone or telephonic apparatus, or any other invention, instrument, or apparatus for the transmission of messages, or the generation, employment, or utilisation of electricity or magnetism, and to carry on the business of transmitting messages, by telephone or other means, or any business connected with the generation, employment, supply, or accumulation of electricity. The subscribers (with one share each) are:—W. Addison, Thomas Lloyd, George B. Frost, Alexander B. Chalmers, Benjamin St. John Ackers, Henry A. Hentsch, and Henry Grewing. The first Directors are:—Messrs. William Addison, Benjamin St. John Ackers, Henry Grewing, Thomas Lloyd, and George B. Frost.

WILLANS AND ROBINSON (LIMITED).—This Company was registered on March 8, with a capital of £300,000, divided into 30,000 £6 per cent. Cumulative Preference and 30,000 Ordinary shares of £5 each, to acquire and take over as a going concern the business of Willans and Robinson (Limited), incorporated in 1888, carrying on business at Thames Ditton, Surrey; with a view to such acquisition to enter into and carry into effect the agreements referred to in Clause 4 of the Company's Articles of Association, and to carry on the business of mechanical and electrical engineers and contractors, boiler makers, iron and metal founders, launch and ship builders, iron and steel converters, metal workers, smiths, wood workers, builders, painters, timber merchants, metallurgists, &c. The subscribers (with one share each) are:—M. H. Robinson, Chatley, Fassett-road, Surbiton, engineer; Sir G. A. C. East, Hall-place, Maidenhead; Capt. M. P. H. R. Sankey, R.N. (retired), Bawnmore, Arterberry-road, Wimbledon, S.W.; G. W. Anderson, Fenwick-chambers, Liverpool; T. O. Lazenby, Tiverton, Devon; P. A. Low, Maybury Lodge, Thames Ditton; James E. Thorn, Red Cottage, Thames Ditton. The number of Directors is not to be less than three nor more than seven. The first are:—Mark H. Robinson, Sir Gilbert A. Clayton East, and Capt. M. P. H. Riall Sankey, R.N.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended March 11th were £930, as against £859 in the corresponding period of last year, being an increase of £71. The total receipts for the half-year amount to £9,474, as against £9,532 for the corresponding period of 1893, a decrease of £58.

COMMERCIAL CABLE COMPANY.—The report of this Company for the year 1893 shows that the gross receipts were $1,842,346, the working expenses $784,600, and the net income $1,057,746. As compared with 1892 these figures exhibit decreases of $48,030, $6,189, and $41,841 respectively. Dividends were paid at the rate of 7 per cent. per annum, absorbing $613,376, and of the remaining $444,370 the sum of $389,600 was applied in January last to the repayment of the remainder of the debenture bonds. The Company's new cable, now being manufactured and laid by Messrs. Siemens Bros. and Co., is to be completed by July 15th. Its guaranteed working speed is to be a third greater than that of the Company's present main Atlantic cables.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment, on April 13th next, of interest of 3s. per share, less income-tax, being at the rate of 6 per cent. per annum on the Preference shares of the Company for the quarter ended March 31st, and the usual interim dividend of 2s. 6d. per share on the Ordinary shares, free of income-tax, in respect of profits for the quarter ended December 31st last. The register of transfers will be closed from April 6th to 13th, both days inclusive.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED). The Directors of this Company have decided upon the payment on account of the dividend of the current year, at the rate of 5 per cent. per annum, less income tax, on the "A" shares of the Company, for the half-year ended December 31, 1893. This will work out as follows:—On the 89,261 Ordinary shares (£3 paid), 1s. 6d. per share; on the 5,000 shares (£5 paid), allotted to the Edison Electric Light Company (Limited), 2s. 6d. per share; on the 12,139 shares (£5 paid), alloted to the Swan United Electric Light Company (Limited), 2s. 6d. per share; less income-tax. The dividend warrants will be issued on the 20th inst.

GOLD RECOVERY PATENTS.—It is announced that the African Gold Recovery Company has resolved to proceed against those companies who have ignored the African Company's patent rights.

HASTINGS ELECTRIC LIGHT COMPANY (LIMITED).—In the Directors' report for the year ended December 31st last it is stated that a considerable sum has been spent on new plant and extensions to meet the large increased demand for electric lighting, and although the receipts are much in excess of last year, the full advantage of the outlay will be derived in the future. The sum of £964. 15s. 7d. remains for dividend. Out of this the Directors recommend the payment of 5 per cent., and the carrying forward of the balance of £75. 11s. 10d. The retiring Directors, Messrs. F. A. Langham, J. Reeves, and J. Woolhams, offer themselves for re-election.

PONTYPOOL ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—At the second annual meeting of the shareholders of this Company a dividend of 2½ per cent. was declared for the year 1893.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have appointed to-day (Friday) the special settling day for the further issue of 20,000 Six per Cent. Cumulative Preference shares, No. 20,001 to 40,000, of the City of London Electric Lighting Company (Limited).

SUBURBAN TRAMWAYS.—The *Financial Times* says:—"It is rumoured that an application is to be made to Parliament next Session for powers to construct an electric tramway from Croydon to join the South London tramway either at Clapham or Tooting, the idea being to eventually extend the line as far as Redhill. If this scheme be put through the tramway might compete to some extent with the Brighton Railway for suburban traffic. At present it is hardly more than talked about."

UNITED ALKALI COMPANY.—A further dividend of 4s. per share is declared, making a total distribution of 5 per cent. for the year ending December last. £42,581 are placed to the reserve fund.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended March 9th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited) were £3,252.

WESTERN UNION TELEGRAPH COMPANY.—A quarterly dividend of 1¼ per cent. has been declared, although only ⅞ per cent. has been earned.

WILLANS AND ROBINSON (LIMITED).—The prospectus is issued of Willans and Robinson (Limited), with a capital of £300,000, divided into 30,000 Six per Cent. cumulative Preference shares and 30,000 Ordinary shares, all of £5 each. 14,463 Preference and 14,462 Ordinary shares, will be allotted in part payment of the purchase-money, and 7,500 shares of each class are reserved for future issue. Applications are, therefore, invited for 8,037 Preference and 8,038 Ordinary shares, payable 10s. on application, 30s. on allotment, 30s. on the 31st July, and 30s. on the 31st October. The Company has been formed to take over and extend the well known engineering business of Willans and Robinson (Limited), of Thames Ditton, Surrey, which was converted into a private Company in 1888. Owing to the vast increase in the demand for the Company's manufactures, large increases are necessary in the works and plant; hence the reconstitution of the Company upon a much extended basis. The new Company takes over the assets and liabilities as from December 29th last, together with book debts and the benefit of contracts in hand. The works at Thames Ditton are freehold, and were rebuilt and fitted with the newest appliances in 1889. In the year 1893 (just ended) the contracts obtained by the Company aggregated no less than 18,950 i.h.p., and a satisfactory increase is announced for the expired proportion of the current year. Out of 23 public lighting stations in London, 19 are engined (16 wholly and 3 partly) by the Company. With the prospectus is issued a list of some of the more important users of the Company's engines and machinery. The necessity for extending the Company's operations is owing to the pressure for orders for electric lighting engines having prevented the old Company from giving adequate attention to other profitable branches of engineering work, large orders for which the new Company will be in a position to execute. In addition to its steam engine business, it is proposed that the new Company shall commence the manufacture of gas engines and water-tube boilers, for which only a small outlay for special plant will be necessary. The old company accept £3,875 in cash and £144,625 in shares. According to the statement of Messrs. Cooper Bros. and Co., dated the 13th inst., the net profits for the past five years are stated to have been £71,955. 8s. 6d., and have shown steady growth from 1889 (£11,052. 12s. 4d.) to 1893 (£18,800. 14s. 10d.), after allowing ample depreciation on an annual average of £4,077. The certified average profits, based upon the previous figures, shows a balance profit equal to 12 per cent. on the Ordinary shares. The Directors, Messrs. Mark Robinson, M.I.C.E. (Chairman), Sir G. A. Clayton-East, Bart., and Capt. H. Riall Sankey, R.E. (ret.), M.I.E.E., are all actively engaged in the business, and have been so occupied for a number of years. Two of them give their whole time to the Company, and are under agreement not to engage in any other business. No alteration is to be made in the existing management or organisation. A feature of the prospectus is that all contracts are disclosed, except those which for trade purposes it is considered unnecessary to enumerate. The expenses connected with the formation and registration of the new Company are borne by the old Company up to and including allotment. The old Company are the promoters. Forms upon which

Digitized by Google

applications for shares should be made can be obtained from the bankers, the London and County Banking Company (Limited), 21, Lombard-street, E.C., and branches; of the solicitors, Messrs. Farrar and Porter, 2, Wardrobe-place, Queen Victoria-street, E.C.; of Mr. Hugh Campbell, 16, Tokenhouse-yard, E.C.; and at the offices of the Company, Thames Ditton, and 14, George-street, Mansion House, E.C. The subscription list will be closed on or before Wednesday next for London, and on Thursday for the country.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 827.—Vol. XXXII. FRIDAY, MARCH 23, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

Mr. Arnold Morley's speech at the Association of Chambers of Commerce on Thursday last, although not addressed specifically to the subjects then before the meeting, was useful, perhaps, if only in proving the futility of arguing with people who are given to riding hobbies, and who invent their own statistics wherewith to feed them. Mr. Morley showed that the figures were wrong and the criticisms unwarranted; but directly his back was turned a resolution was adopted reaffirming the complaints, as well as the erroneous calculations on which they were based. The same fate, no doubt, would have awaited anything he might have said on the question of Anglo-French telegraph rates, which, however, he seems to have discreetly passed over in silence. On the other hand, he spoke very openly and sensibly as to a matter which has been broached more than once, although not yet included in the programme of the Association, namely, the adoption in this country of "express telegrams" which prevail on some Continental systems. Mr. Morley's conclusions are so sound that we will not quarrel with his arguments; but we think he could find a better reason for rejecting preferential telegraph rates than the one which describes his customers as a democracy. In the first place it is not true, and in the next it has no more to do with the question than with the prices of top hats. If Mr. Morley wants to be truly democratic he must curtail the privileges enjoyed by the comparatively few who send many telegrams, and extend those privileges to the many who send few telegrams, a task which a democratic Postmaster-General would find rather difficult and extremely unprofitable. The true objection to express telegrams is that they force higher rates upon those who can afford to pay them, and cannot afford to be outstripped by their competitors. This, so far from being democratic, is rather aristocratic; and we may make Mr. Morley a present of it in case he has a mind to recommend it to the Chancellor of the Exchequer by way of making the forthcoming Budget more democratic even than it is expected to be.

With the revival of trade we have the company promoter with us once more, conjuring, as of old, with "that blessed word" Electricity. In our issue of February 16th, after exposing the fallaciousness of sundry comparisons that had been put forward, we so far stretched our charity as to refer to the Livet system of refuse destruction as "a genuine and satisfactory *attempt*." This week the public is invited, on the strength of this attempt, to subscribe £600,000. On this modest sum the Company will work the Livet patents all over the universe—no, in "London and twenty miles round." The estimated annual revenue is on an equally grandiose scale; nothing short of half a million sterling will satisfy the prospectus artist. The basis upon which this magnificent superstructure is reared is the assumption that on "the Livet system three tons of rubbish create the same steam power as a ton of best coal"; ten tons of refuse and one ton of average coal would be more like the truth. No less than £318,000 of the annual total income of £515,000 is to be derived from a portion of the saving effected by metropolitan electric light producers by using the Livet system. How this saving is to be on a coal bill of some £50,000 we do not exactly see, albeit this magic system "has been in operation at Halifax for many months" producing by means of a Parsons steam turbine and a small projector a result said to be equivalent to "250,000 electric candle-power." These are only two out of a sheaf of misleading statements; as to the rest of them, are they not written in the advertisement columns of all the daily papers?

For ten years and more, questions connected with the design and construction of apparatus for generating and measuring electrical energy have occupied the attention of the Institution of Electrical Engineers, almost to the entire exclusion of other matters. That this should have been so was quite natural; there was nothing else of equal importance to discuss. But to-day the centre of interest has shifted. Everyone now admits that anyone's alternators will run in parallel, given a suitable engine with a suitable governor, or better still with no governor at all. With this much debated point settled to the satisfaction of all concerned, the last outstanding question of importance in connection with dynamos has been threshed out; may we now be permitted to follow the good example of the Northern Society of Electrical Engineers, and to pass from dynamos, wattmeters, *et hoc genus omne*, to topics of more general interest, such as the management of central stations and the behaviour of underground mains. Academic papers on "The Ideal Central Station," or "The Perfect System of Mains," are not called for, but contributions only from those who have had actual practical experience of the matters they write about.

The article which we publish this week on a "Workshop Method of Testing Iron" is of some interest in connection

Digitized by Google

with the recent discussion at the Institution of Electrical Engineers on this subject. Mr. KAPP, in common with many other engineers, has been using a wattmeter method of determining hysteresis losses, and the value of this simple means of measurement can hardly be overstated, provided certain conditions are observed; one of these conditions being the elimination by calculation of eddy current losses from the total loss. Mr. FELDMANN shows us good reason for believing that the formulæ at present in use for the purpose agree with the results of observation, thus answering to some extent the question put in our leading article of March 2nd.

THERE remains a source of error not alluded to in Mr. FELDMANN's article. Can it with safety be assumed that the reading of a Cardew voltmeter is a measure of the maximum voltage to which it is subjected?—for the induction is calculated on this assumption. In other words, are modern alternators so near a sine function in their electromotive force wave that the Cardew voltmeter reading the square root of the mean square of the volts may be taken always to read the same sub-multiple of the maximum pressure? In the cases dealt with by Mr. FELDMANN this appears to have been so, judging by the results which he obtains when working on this assumption. But it does not seem desirable or safe to assume this in every case without some experimental determination of the shape of the wave itself; and this circumstance, combined with the amount of calculation required, makes a true "Workshop" Method of Testing Iron still an unattained ideal.

FARADAY did not exhaust his subject when he delivered his Christmas lectures on "The History of a Candle." Prof. STOKES described a very pretty experiment some years ago, showing that the flame of a candle is a thin luminous cone. This experiment, which is easy and fascinating to repeat, consists in focussing the sun's rays by a lens on the flame. When the focus is brought to the middle of the flame, two bright discs are seen where the cones of light enter and emerge. The sunlight thus concentrated illuminates the solid particles of carbon to a much higher brilliancy than that due to the heat of the flame, and thus proves that they are solid. In another column will be found some observations by Herr P. GLAN on the dimensions of a candle-flame. He speaks of the volume of the brilliant portion of the flame. This luminous sheath is very thin, as may be shown by Prof. STOKES's test, when the focus of the sun's rays is brought to bear on it. Herr GLAN does not call attention to the fact that a candle flame is of an oval section, due to the curvature of the wick, but, of course, he must have observed it. It is the practice to place the two candles in a photometer with the planes of the wicks at right angles to each other, but the flame is so nearly transparent that this precaution is generally unnecessary. A modification of Prof. STOKES's experiment might be tried with a thin horizontal slice of sunlight, by which the cross-section of the flame at different levels might be examined. The mean projected area of the luminous part of the flame of a standard candle is, as has been already recorded in these columns, about half a square inch, and the brilliance is therefore two candle-power per square inch.

IN the first number, which has recently made its appearance, of *Elektron*, an American monthly magazine devoted to electrical interests, there is an interesting account of the construction and working of the buoy-lighting of the waterway between Chicago and the recent exhibition. The buoys were placed at half-mile lengths, and were connected by means of armoured cable, the armour consisting of galvanised iron wire wound spirally over the insulation. It was originally intended to run the glow lamps from transformers, and each lamp was designed to take 5·2 amperes. It was found, however, that with the normal pressure of 1,450 volts, no more than 1·5 amperes were going through the lamps. On increasing the line pressure to 3,300 volts, the author states, the current was only 1·2 amperes; though it is difficult to see how an actual reduction of the current could occur under these conditions. At any rate, it was found to be impossible to obtain the proper lamp current; so the alternating system was abandoned in favour of the continuous-current series system. The failure of the alternate-current system was attributed by the American engineers to the spiral armoured cable, which "acted as a condenser." It is more probable that it acted like a gigantic choking coil; and on the spot it would have been quite easy to have ascertained if the effect was electrostatic or electromagnetic. The paper does not give us sufficient data to enable us to be dogmatic; but the probability seems largely in favour of the phenomenon having been caused by the magnetic field generated in the armour.

LAST week we discussed at some length the criticism made by the *Journal of Gas Lighting* on our recent comparison of the cost of electric light and of gas. Our attention has been called to four words in this criticism, which fully explains it. Referring to the diagram on page 143 of our present volume, our contemporary observes, "What it does show at the first glance is that in order to make out a fictitious effect," &c. The six times repeated datum of comparison in the body of the preceding article is neglected, and we are judged by what somebody sees "at the first glance." Next time we venture to discuss the common glow lamp, and adorn our remarks with an illustration thereof, some light-hearted critic will mistake it "at the first glance" for a balloon, and will comment severely upon the folly of constructing aeronautical apparatus from a receiver made entirely of glass, from which the air is exhausted, and having leading-in wires, &c.

Telephone Extensions.—Telephone communication between London and Dover and other towns in Kent was established on Saturday by the National Telephone Company.

Cable Interruptions:

	Date of Interruption.
Cayenne-Paramaribo	Oct. 15th, 1893.
Bissao-Bolama	Nov. 24th "
Garachico-Santa Cruz de Palma	Dec. 27th "

The Boat Race.—The Direct United States Cable Company succeeded in transmitting to the United Press of America the announcement of the result of the Oxford and Cambridge boat race, rowed on the Thames on Saturday last, ten seconds after the despatch was filed in London.

British Association.—At the coming meeting of the British Association, at Oxford, Prof. A. W. Rücker will preside in Section A (Mathematics and Physics), and Prof. Kennedy in

Digitized by Google

Section G (Mechanical Science). Sir Douglas Galton will be proposed as President for the meeting in 1895, at Ipswich.

Oldham.—The Oldham Corporation on Thursday night last for the first time lighted the principal thoroughfares of the town and the public buildings by electric light. The plant is sufficient for 2,500 glow lamps of 8 c.p. The Corporation obtained power to borrow £27,000 to carry out the scheme, which has been superintended by Professor Kennedy.

Gas v. Electric Cars.—The *Journal für Gasbeleuchtung*, 1893, Nos. 33 and 34, has a detailed Paper by Prof. Baron Gostkowski, of Lemberg Technical High School, on gas cars. The learned professor's dictum is that the gas car is 24 per cent. cheaper to run than the electric car, and that the electric car with overhead wires has a past, while the gas car has a future.

Long-distance Telephony in India.—A successful telephone experiment was tried in Ceylon on February 2nd. Telephones were attached to the telegraph wires, and Colombo was placed in speaking communication with Trincomalee. Almost simultaneously a series of experiments was carried out in Calcutta, direct telephonic communication being established between Calcutta and Nagpur, a distance of 760 miles.

Lyons Exhibition.—At the Lyons Exhibition, which opens next month, an electric tramway connecting the centre of the town with the Exhibition has been laid down. The dynamo used for obtaining electrical energy is driven by a gas engine. The system of transmitting the current to the car has been patented by MM. Claret and Vulleumier, and consists of magnets laid under the ground, and making contact with a conductor rail as the car goes along. A trial of the system has already been made at Clermont, it is said, with success.

India and the Electrical Conference.—When the Committee which arranged the Electrical Conference at the World's Fair was discussing the matter, says the *Madras Times*, it was proposed to put India on the list of invitations, but some member of the Conference asked why "Indiana" should be specially represented and none of the other American States. Those present thinking India was short for "Indiana" accordingly struck it out of the list. That is how it came about that India was not asked to send a representative. Such is fame!

Royal Institution.—The following are some of the lecture arrangements after Easter:—Prof. J. A. Fleming, four lectures on Electric Illumination; Prof. Dewar, three lectures on The Solid and Liquid States of Matter; Capt. Abney, three lectures on Colour Vision (the Tyndall lectures). The Friday evening meetings will be resumed on April 6th, when a discourse will be given by Prof. Victor Horsley, on Destructive Effects of Projectiles. Succeeding discourses will probably be given by Prof. J. J. Thomson, Prof. A. M. Worthington, Prof. Oliver Lodge, Prof. C. V. Boys, and others.

Electrical Engineering at Sheerness.—In the course of a speech in the House of Commons on Monday evening on the question of the wages of dockyard *employés*, in which he stated he was "for uniformity, discipline, good work and trade union hours and wages," Mr. John Burns stated that "at Sheerness the most delicate and complex electrical engineering work was being made by apprentice shipwrights but twelve months out of their time. It was simply absurd to think that these apprentices were competent men to place in charge of electrical machinery on board a large ironclad."

Principal Chemist of the Government Laboratories.—The Government has decided to place the direction of the Customs and Inland Revenue Laboratories under one administrative chief, to be styled the Principal Chemist of the Government Laboratories. The Principal Chemist will also receive references from the Board of Agriculture, the Local Government Board, and other Government departments. The appointment, which is in the gift of the Treasury, has been offered to, and has been accepted by, Prof. Thorpe, F.R.S., who thereby vacates the Chair of Chemistry in the Royal College of Science, which he has held since 1885.

Earth Forward and Return Circuit.—According to a daily contemporary, the Abbé Michel has succeeded in using two separate horizontal geological strata as a telephone circuit. The strata are conducting, and are separated by an intermediate stratum of comparatively insulating material. By coupling the transmitter to the surface stratum and a deep stratum, and similarly coupling the receiver, it was found that speaking could very well be carried on at a distance of 120ft. Very rarely would the geological conditions permit of this arrangement being adopted; while in any case, of course, it would be impossible to have more than one system in the same locality.

Electrical Utilisation of Water Power in Switzerland.—The Commission appointed to examine the tenders for the utilisation of the hydraulic power of the Areuse for the purposes of lighting and transmitting power to Neuchatel, has given its award. The first prize of 5,000 francs has been awarded to M. Alioth, of Basle; the second of 4,000 francs to M. Ramel, of Zurich, and the Zurich Telephone Company; and the third of 3,000 francs to Prof. Palaz, of Lausanne, and M. H. Etienne, of Neuchatel. The members of the Commission were Prof. Weber, of Zurich; M. Picou, of Paris; M. Colombo, of Milan; and M. Hipp, who died during the sitting of the Commission.

Subterranean London.—It gives an impressive idea what subterranean London is fast becoming, says the *Daily News*, to learn that on emerging from the river the new City and Waterloo line will, in its passage up Queen Victoria-street, run for a part of the way underneath the low level main sewer, which in its turn runs along beneath the District Underground Railway. So that at this point in the City we shall have first a busy main thoroughfare, below that a steam railway, then a huge metropolitan sewer, then an electric railway, reaching its terminus at a depth of about 63 feet below the streets, and here it will communicate with another line—the Central London—which will lie at a depth of 80 feet.

Recording Electric Railway Fog Signalling Apparatus.—There is now at work on the bridge over the Boundary-road, close to the Hoe Street Station of the Tottenham and Forest Gate Railway, an invention which should prove useful to railway engineers and engine drivers. The invention consists of a visual, and audible, and permanently-recording electric fog signalling apparatus, and has the following main objects: In the first place, it gives a repeat signal to the locomotive driver of the position of each signal as he passes it, whether the signal be at "danger" or at "line clear." In the second, place, it repeats the signal in the signal cabin. The repeat signalling apparatus on the locomotive consists of an indicating needle or arm on a dial, also two bells or a bell and a gong. There is also a recording index. The system is being brought out by Mr. I. A. Timmis, the inventor of the automatic electric signals on the Liverpool Overhead Railway.

The Brilliance of a Candle Flame.—That the luminosity of a candle can be calculated direct from the dimensions of its flame, is the rather striking theorem of Herr P. Glan, who gives the results of his measurements in the current number of *Wiedemann's Annalen*. The volumes of the bright portions of various candle flames were measured by taking the length by means of a scale placed behind the flame, and the breadth at various points by gauging it with calipers or compasses. These bright portions have approximately the shape of cones, each of these cones being penetrated from below by a truncated cone, consisting of the dark central portion. The difference between the volumes of the two cones gave the volume of the brilliant portion. Stearine and paraffin candles of various thicknesses, and provided with different wicks, were compared by means of a rod photometer. It was soon found that the height of the flame was not the only factor determining the brightness. A stearine candle of 5·88cm. circumference had, on the other hand, a higher luminosity than another 6·49cm. in circumference. But a determination of the ratio of the volume to the illuminating power showed that this ratio is very nearly constant, the difference between the actual luminosity and that calculated from its volume never exceeding 3 per cent. In other words, equal volumes of the bright flame of any two candles give out the same amount of light.

The Electric Light and the Auer Gas Light.—The following statistics, supplied by the Stockholm central electric station and by the Stockholm Electric Light Company, throw an interesting light upon the effect produced upon electric lighting in Stockholm by the introduction of the Auer gas light in that city. The latter light was introduced in Stockholm in the autumn, 1892, the same time as the electric central station was opened. The immediate effect was the loss of one subscriber for 12 16-c.p. lamps. At the end of the year the station was supplying a total of 4,750 incandescent lamps, which during 1893 increased by 2,750 lamps, making a total of 7,500, the increase on the year being equal to 58 per cent. During the same year the station lost two subscribers, with a total of eight lamps, who adopted the Auer burners. From January 1st to February 22nd this year there was an increase of 102 lamps, from which must be deducted the 21 lamps of one subscriber, who went in for the Auer light. It will thus be seen that during all that time the central station only lost four subscribers, with an aggregate of 41 lamps, or about 0·5 per cent. The Stockholm Electric Light Company had at the beginning of 1893 a total of 5,052 lamps of 16 c.p,, which, at the end of the year, had increared to 5,567 lamps. The Auer burners cannot, therefore, be said to have done the electric lighting establishments much harm, although there is reason to believe, says our Scandinavian correspondent, that the number of people requiring electric light would have been larger had not the Auer burners been in competition.

Thin Metal Partitions in Voltameters.—In a second Paper, "On the Polarisation upon a Thin Metal Partition in a Voltameter" (in the *Philosophical Magazine* for March), Mr. John Daniel discusses the passage of ions through a gold-leaf partition, and also the minimum current strength at which the ions are deposited visibly upon the partition for various electrolytes. In order to investigate the first point two similar voltameters with metallic partitions were set up at the same time, and, without passing the current, quantitative analyses of the solution on the two sides of the partition were made at stated intervals; then the current was passed, the voltameters being in series, quantitative analyses being again made of the solution on the cathode side, and the weight of copper deposited on the kathode determined, and finally the circuit was broken and the analyses again repeated. Curves plotted from these results show no break nor change of slope for the intervals during which the current was passing. Thus it would appear that the current does not sensibly affect the diffusion of copper sulphate and sulphuric acid through a gold-leaf partition. In the experiments on the "critical current" it was found that the concentration of the electrolyte exerted an important influence on the value obtained, and the measurements made indicate that the "critical current" is proportional to the conductivity of the electrolyte. Experiments made to determine whether the variation of the temperature has the same effect upon the "critical current" as upon the conductivity are not yet sufficiently complete to justify conclusions being drawn.

Electrical Communication with the Kentish Knock Lightship.—It is satisfactory to chronicle the fact that the Kentish Knock Lightship was last week placed in electrical connection with the shore. This lightship is 18 miles from the nearest land, and is moored in about 12 fathoms at low water. She is exposed to heavy seas, especially when the wind is easterly. The nearest land is the North Foreland, and it is from the post-office at Kingsgate that the cable is run to the lightship. Owing to the much more exposed position of this vessel than that of the Sunk, it has been necessary to adopt greater precautions in respect of the moorings. Instead of two arms of moorings there are four—*i.e.*, there are four mushrooms placed in relation to the ship's position N.E., S.E., S.W., and N.W. Four chain cables, each about 210 fathoms long, from these mushrooms are brought together at a centre swivel, the patent of Mr. F. Bedwell, of the Telegraph Construction and Maintenance Company, and connected to the four outer loops of the swivel, and from the swivel two chain bridles pass into the ship. The swivel has to be kept about six fathoms above the sea bottom, and thus it will be seen that the vessel has to carry a great weight from her bows. The cable was laid by the Post Office cable ship "Monarch," and at three o'clock on Wednesday afternoon last week a message was sent through from the lightship to the General Post Office, to the effect that the first of the permanent lightship cables had been successfully laid and communication established.

The New Transandine Telegraph Lines.—The direct telegraph lines extending from Buenos Ayres (Argentina) to Valparaiso and Santiago (Chili), which have been established by the Pacific and European Telegraph Company, of which Sir John Pender is Chairman, were opened for traffic on Monday last. From the Atlantic coast to Uspallata on the spur of the Andes, a distance of about 697 miles, the line is aerial on iron poles, and is of the latest type of construction. Thence to Rio Blanco, in Chili, underground cables are laid in about 75 miles of trench through the highest and wildest part of the route, where heavy snow falls in winter would sweep away any telegraphs erected above ground. The lines from Rio Blanco to Valparaiso and the branch to Santiago, consisting together of about 160 miles, are aerial. The total length of the line, which extends from the Atlantic to the Pacific coast, is about 927 miles. Arrangements have been made by which the telegraph lines have been erected adjacent to the railway lines, and exceptional facilities are thus afforded for the efficient maintenance of the wires. There is only one station, which is at Mendoza, but Buenos Ayres and Valparaiso work direct with each other. The opening of this system is of great importance to the West Coast of America Telegraph Company, as it places their cables in direct connection with those of the Western and Brazilian, the Brazilian Submarine, and the Eastern Telegraph Companies, affording a continuous chain of telegraphs in British hands from England and the Continent to the Pacific Coast of South America. The construction of this line was rendered necessary to enable the English Submarine Telegraph Companies to transmit with great rapidity the important traffic to and from the West Coast of South America, where it is dealt with by the cable of the West Coast of America Company.

Electric Light Plant and High Efficiencies.—The following letter has been addressed by Mr. J. S. Raworth to the *Cheltenham Examiner* in regard to the recent tenders for electric light plant for Cheltenham :—

SIR: I observe in your report of the Town Council meeting, published in your issue of the 7th inst., that the Electric Lighting Committee reported on the tenders received for plant, and advised that the tender of Messrs. Siemens Brothers and Co., of Westminster, with "Willans" engines, at £4,610, less £365 for boiler, be accepted. It was afterwards explained that this tender was £745 higher than another tender, the reason adduced for the payment of the extra sum being "greater efficiency." This is an excellent reason; in fact, it is economical to pay even as much as 40 or 50 per cent. additional price for plant of 10 per cent. additional efficiency, and in agreeing to pay for extra efficiency, the Committee have shown their business-like appreciation of a good bargain. As a rule committees are too much inclined to take up with the cheap and nasty article rather than face the trouble of justifying their conduct in paying a high price for one that is first-class. In this instance your Committee appear to have justified their recommendation on the evidence placed before them, that a Willans-Siemens combined engine and dynamo at Glasgow has produced an efficiency of 88 per cent. I need scarcely say that 88 per cent. is a splendid efficiency and is worth paying for, in comparison with the ordinary commercial article, which realises an efficiency of from 64 to 76 per cent. only. The highest recorded efficiency with a "Willans-Siemens" combination for alternate currents is 76 per cent., which was obtained at Bristol, and it is noteworthy that the 88 per cent. case, which the Committee quote, refers to Glasgow, where the dynamos *are not high tension* but *low tension*, and where the current is *not alternating* but *continuous*, and consequently, the case quoted has no bearing on the subject whatever, and it is quite possible that your Committee may find that after parting with £745 of the ratepayers' money on the assumption that they are going to get for it an efficiency of 88 per cent., they have after all only obtained the ordinary commercial article with 76 per cent. efficiency. I should be sorry to write this letter if I could not close by holding out a rayof hope to the Committee that they may yet get their aspirations for high efficiency plant satisfied, and that without paying an extra price for it, and without sacrificing any practical advantages whatsoever. The Brush Electrical Engineering Company guarantees its plant as tendered to have an efficiency of 84 per cent., and will even guarantee 86 per cent., provided the tests be carried out by a careful and independent engineer, such as Prof. Kennedy. Plant of this character may be seen working in London, of an aggregate power of 4,000 h.p., and the efficiency demonstrated beyond a doubt. It is, therefore, just the plant which your Committee desire to obtain and are willing to pay an extra price for, but in this case there is no extra price to pay. The efficiency is proved and guaranteed to be 8 to 10 per cent. better than that of any other existing plant, and your Committee will, I am sure, be pleased to hear that they may obtain these guaranteed advantages and at the same time save £745.

ON CATHODE RAYS IN GASES UNDER ATMOSPHERIC PRESSURE AND IN EXTREME VACUA.

BY PROF. G. F. FITZGERALD.

Herr P. Lenard has made a most interesting communication to *Wiedemann's Annalen*, No. 2, 1894, upon the above subject. The subject of the investigation is the actions that take place in the so-called dark space surrounding the negative pole in a Geissler's tube. Hittorf seems to have been the first to observe that within this region something of the nature of propagation in rays was taking place, and this has been further studied by innumerable experimenters, of whom Crookes made, perhaps, one of the most important observations that these rays, when falling on a solid, tended to press it away from the cathode.

These rays were supposed to be unable to get through solids until Hertz, in 1892, showed that thin metallic films do not stop them, and Herr Lenard has further shown that thin films of any solid are quite permeable to these rays, thus throwing doubt upon Prof. J. J. Thomson's suggestion ("Recent Researches," p. 126. Note) that the solid acts as an intermediate cathode. This seems also inconsistent with the observation of Herr Lenard that these rays can be propagated into vacua, where an ordinary cathode cannot start rays of its own. Herr Lenard has made such a number of beautiful and most interesting observations that those who wish to study the subject at all fully must refer to his paper, a translation of which is appearing in *The Electrician*. Only the more important experiments and his conclusions therefrom can be noticed in this preliminary account and criticism.

Working upon Hertz's observation that these rays were capable of penetrating thin metallic films, Herr Lenard tried whether they could extend out into the air at ordinary atmospheric pressure. With this end in view he arranged a very small hole 1·7mm. in diam. He cemented a piece of aluminium foil 0·00265mm. thick (7·7 times as thick as common aluminium foil). This thickness of foil is quite opaque to light, and easily stands the pressure of the atmosphere over this small hole. A cathode is arranged so that the cathode rays are discharged normally to this window, and he found that there was a faint glow in the air outside the window when the cathode rays impinged upon its inner surface. This glow extended visible to a distance of 5cm. from the window. Inside it any substance which becomes phosphorescent under the cathode rays in ordinary vacuum tubes glowed brightly, and this phosphorescent effect exists to distances of 8cm. from the window. In air at ordinary pressures this action occurs equally in all directions outside the window, but when the gas in the space outside is at a low pressure the rays are propagated normally to the window and in right lines. The diffusion of the rays by ordinary gases is compared to the diffusion of light by a turbid medium like milk, and Herr Lenard has shown that this apparent turbidity of the gas depends entirely upon its density, Hydrogen being the least turbid, and sulphurous acid, with a density of 32, being the most turbid or ray scattering of the gases he had tried.

Herr Lenard further showed that any solid, if thin, transmitted these rays as well as aluminium foil. Transparency or opacity to light did not seem to affect the question at all. Mica, glass, collodion, soap-bubble films up to 0·02mm. thick: These films consist of thousands of molecules in thickness, and it is impossible to suppose that they contain any holes through which the molecules composing the supposed cathode streams of molecules that Crookes's experiments seem to suggest could penetrate.

Some of the most interesting experiments were those made into vacua, which were so far exhausted that a coil capable of producing sparks of 15cm. in air, could not produce any discharge between terminals sealed through them. Herr Lenard estimates that when he had condensed the mercury vapour in a connected globe by lowering it to a temperature of $-21°$C., the pressure of the remaining gas was about $0·03 \times 10^{-6}$ of an atmosphere, *i.e.*, about 0·03dyne per sq. cm.

In these tubes nothing was visible on the path of the rays, but where they impinged on the glass at the opposite end of a tube 150cm. long, and when there were no magnets near, they were propagated in right lines.

From these and many other interesting observations Herr Lenard concludes that, as was believed by E. Wiedemann, Hertz, and Goldstein, these cathode rays are a phenomenon in the ether and are independent of the presence of matter. If this be so they are a most remarkable addition to the properties of the ether. Phenomena that may all be classed under light propagation are the only known phenomena of propagation in free ether. There is a very essential difference between these cathode rays and ordinary light propagation, and only for this these rays might be very rapid ultra-violet waves, which are known to be rapidly absorbed by air and other gases, but which may be able to run the gauntlet of hundreds of thousands of molecules without being finally absorbed, and might, in accordance with the known transparency of gold leaf, be able to penetrate any solid, even though a conductor, because for their extremely rapid vibrations the molecular motions upon which ordinary conductivity depends may be much too slow to have any sensible effect. The fact that seems conclusive against this view is the deflection of the rays by a magnet. There seems no reason to think that light rays are deflected by a magnet. These rays are deflected in the same way as a conductor carrying a current of electricity away from the cathode. No such action has ever been observed on rays of light. It would be most natural to explain the action by the presence of the matter which is generally required in order to be acted upon by a magnet. There seems very little reason for supposing that a magnet would act upon electric displacement currents in the ether, even if displacement currents of the straight ray kind were possible in the ether without propagating themselves out sideways with the velocity of light. If, however, the action of the magnet be not upon the ray but upon the emitting surface, as has been shown to be the cause of the repulsion of two cathode rays for one another, then there seems to be some reason for thinking that they may be very intense ultraviolet radiations, though their pressure upon matter could then hardly be as great as has been observed. When we recollect that in the vacua described by Herr Lenard there are still 10^{10}, *i.e.*, ten thousand million molecules per cubic mm., there does not seem sufficient reason for looking to an unknown property of the ether when there is so much matter present to explain the phenomenon. Herr Lenard lays great stress on the difficulty of producing electric discharges in these high vacua. This may be due to the difficulty of producing the anode part of the discharge and not of producing the cathode phenomena which are known to be quite secondary to the actual discharge, and Herr Lenard's experiments prove conclusively that this radiant state is a phenomenon independent of the principal part of the discharge. Professor J. J. Thomson mentions a case in which a discharge preferred to pass through a long spiral tube rather than across a distance of 1mm. because there was not room in this short distance for the positive discharge to take place. Herr Lenard also lays stress on the fact that the high vacua did not deteriorate under the action, so that there seemed very little reason to suppose that anything that might be called cathode matter was carried through the window. In this connection it must be remembered that most electric actions in gases and liquids are accompanied by streams of molecules in both directions, and that it may be that as many molecules were carried out of as into the vacuum. Another supposition might be that the cathode property of propelling these molecules from its surface was transferred through it, from molecule to molecule, after the manner of electrolytic conduction, and that no molecules were transferred into the vacuum at all. Suppositions of this kind seem much more probable, and can explain the experiments upon the same basis as other phenomena of electric discharges without supposing that we are dealing with a new etherial property. These very high vacua with their long free paths of their rapidly moving molecules are just the media in which rays such as are observed producing considerable pressures where they impinge might be expected to exist. The dissociated molecules in such a space, with 10^{10} molecules per cubic mm., have a charge of 1,000 electrostatic units per cc., and moving at a moderate

Digitized by Google

molecular rate of four or five hundred metres per second would carry a current of a tenth of a milliampere, quite as much as is likely to be going in these streams. In such very high vacua there would not be any large pressures produced by the impacts of these molecular streams, about a thousandth of a dyne per sq. cm. might be expected, not if the velocity of the streams were much greater than that of gases at the temperature of the experiment, as would be likely, they might easily produce pressures in less perfect vacua, such as would account for the mechanical effects observed by Mr. Crookes. Herr Lenard does not seem to have tried whether his filtered cathode rays produced pressures such as Mr. Crookes observed. These pressures may be partly due to the electrification of the surface in the same way as the cathode, or as the molecules in its neighbourhood, in somewhat the same way as a point is repelled by the air in its neighbourhood.

In apparent connection with this whole subject are the interesting observations of Mr. Daniell (*Phil. Mag.*, 1894) upon the transference of electrolytic action in liquids through thin metallic plates. If this be not due to small holes in the plates, view that Mr. Daniell seems not to have fully disproved, and that is confirmed by his statement that the liquid can diffuse through his metallic partitions, these actions, and others that have been noticed, seem to point to electrolytic actions being, in that form, transmitted through small distances in metallic sheets. Mr. Daniell does not seem to have tried other diaphragms than metals, and although their non-conductivity might stop all continuous action through them, it might be worth while trying whether they would transmit electrolytic actions in the same sort of way as he has found thin metallic plates will. Herr Lenard's actions and other discharges in gases, being so abrupt and discontinuous, might easily be transmitted by bodies which could not accommodate themselves to the continuous action of electrolysis in a voltameter.

In conclusion, we may refer to the translation of the original Paper which appears below for further information on this extremely interesting subject, and for a statement of Herr Lenard's views upon his admirable investigations.

ON CATHODE RAYS IN GASES UNDER ATMOSPHERIC PRESSURE AND IN EXTREME VACUA.*

BY PHILIPP LENARD.

1. If a Geissler tube is sufficiently exhausted almost all the phenomena attached to the anode, and those which mark the course of the electric discharge, are eliminated, and the phosphorescence-producing rays proceeding from the cathode—the rays discovered by Hittorf, and studied by Crookes as radiant matter—attain a high development. These rays, although due to the electric discharge, yet show a distribution which is perfectly independent of it. Whilst thus sharply marked off from the discharge itself, they appear by all their properties as a phenomenon analogous to light; but though very similar to the latter in the geometrical character of their propagation, they show decided differences in essential properties. Differing from light as regards their capacity of penetrating solid bodies, the cathode rays in our vacuum tube end where they impinge upon the glass walls. But what would happen if the walls were made transparent for cathode rays? To answer this question experimentally seemed no longer impossible since Hertz had shown that the ordinary metallic films are strongly transparent for cathode rays, even in three or four thicknesses. It is true that these films are very delicate and never free of holes, and thus not directly adapted to my purpose. But the cathode rays do not penetrate through the holes, but through the material of the films.†

It soon appeared that even 15-fold layers of ordinary aluminium foil are strongly traversed, especially by cathode rays suitably produced. Among a number of stronger aluminium films of various thicknesses, which I subsequently obtained, I found one just strong enough to resist the one-sided pressure of the atmosphere on a small surface, free from holes, and only eight times as thick as ordinary aluminium foil. This film was capable of forming a transparent air-tight shutter on a vacuum tube, and of allowing the cathode rays a free exit into the open air. Whether they would avail themselves of it was, of course, not to be predicted. The experiments now to be described will not leave a doubt on that point. Once produced, the cathode rays are propagated into air-filled space, and that to distances of nearly 10 centimetres. The observation of the rays can thus be transferred from the vacuum tube into the open; they can be investigated in any medium. But, in particular, observation and production are made perfectly independent of each other; the conditions of the former may be varied without affecting the latter.

A special interest attaches to the possibility of making the rays enter a perfect vacuum, in which we know they cannot be produced; it means the possibility of performing in this case the same fundamental experiment as that which decided whether light and sound were occurrences in matter or ether. As will be seen, the vacuum offers no impediment to the propagation of the rays. They traverse it with great intensity to distances upwards of a metre; they are thus characterised as occurrences in the ether. Considering how little we know about the ether they can thereby only increase our interest in them.

The Apparatus.

2. After successive modification of almost all the parts of the vacuum tube it was given the form shown in section in Fig. 1, E E. K is the cathode, a circular plate of aluminium, 12mm. in diameter; it is attached to a long handle, which is completely surrounded by the very thick-walled glass tube, K l, and is fused in at l. The glass tube fits well into the neck, h h_1, of the vacuum tube, and is cemented air-tight at h_1. The anode, A A, is a piece of brass tubing which just fits into the vacuum tube, and allows the handle of the cathode to project by 12mm. The platinum wire, *p p p*, maintains the anode in position, and serves as a conductor; it is fused into the tube, R, leading to the pump. Opposite the cathode the vacuum tube is closed air-tight by a strong metal cap, *m m*, and cement. Fig. 2 shows this cap in three-quarter natural size. It is perforated in the centre, at F. Over this perforation 1·7mm. wide, the outer rim of which is carefully rounded off, is laid the thin aluminium plate, A l,* which is attached by cement applied all round.† This shutter, which is transparent to cathode rays, and perfectly opaque to light and air, we will call the *window*, and the space to the left of it in the figure we will call the *observing space* (*Beobachtungsraum*). The window is attached so as to be in good metallic contact with the cap, which is, like the anode, connected to earth. To prevent the window acting as anode, which would lead to corrosion, the inner metallic protecting cover, V, is fixed so as to leave an opening of not more than 3 mm. diameter for the cathode rays. The vacuum tube is surrounded by a tin box, G G, to which is attached in front the large tin screen, S S, which only leaves the window free, and is blackened on the side of the observing space. This box and the screen, which are put to earth, protect the observing space from the light and the electric forces of the discharge.

The most suitable vacuum is that which is obtained when the difference of potential between the electrodes corresponds to a sparking distance of about 3 cm. between spheres in air. To enable the observer to control this sparking distance and vacuum at any time, the adjustable spark-gap, B (Fig. 1), is introduced as a shunt to the vacuum tube. With increasing exhaustion the sparking distance rapidly increases. At lower vacua than that specified cathode rays are produced which penetrate less easily through the window; at higher vacua the discharge tube runs the risk of being injured.‡ The induction coil used, with a mercury interruptor giving about six interruptions per second, and four accumulators gave sparks up to 15cm. in length between spheres. The vacuum tube was permanently attached to the pump, a Geissler mercury pump, for although the vacuum, when not used, remained unim-

* *Wiedemann's Annalen.*

† Hertz, *Wied. Ann.*, 45, p. 28. 1892. E. Wiedemann and Ebert pointed out the transparency of cathode coatings in vacuum tubes about the same time: "Sitz. Ber. Phys. Med. Soc. zu Erlangen," December 14, 1891. I had already long ago tried to construct a tube with transparent shutter, but without success, by using a quartz plate 1mm. thick. Prof. Hertz himself urged me to employ metallic films; for this and many another valuable suggestion I owe him a debt of gratitude.

* 1 sq. cm. of this foil weighs 0·000715 gr., and is therefore 0·00265 mm. thick (7·7 times as thick as common aluminium foil); it may be easily handled and cut with the scissors. It is the "once-beaten aluminium of metal foil makers, and may be had from any of them as an intermediate product. But not every maker produces films sufficiently free from holes. The only suitable kind out of three which I obtained is of unknown origin. Foils of twice this thickness, which may be employed with almost equal success, are more easily obtained reasonably suitable. Holes which transmit air are always visible with a lens in a strong light, and are easily avoided.

† For the window I use marine glue, for the other joints sealing-wax covered with marine glue. Sealing-wax alone shows cracks after a time; marine glue alone would be pressed through the joints by the atmospheric pressure.

‡ The glass covering of the cathode wire is sometimes penetrated, especially between h and h_1. This danger is much diminished in a tube where the glass covering is fused into the vacuum tube, and the window is attached to a platinum tube fused in, thus avoiding any further cementing.

Digitized by Google

paired for weeks together, yet the pressure during the working always increased perceptibly, so that from time to time the pumping had to be renewed. The precaution was taken of only setting the interruptor going for the few seconds necessary for an observation; thus the window was protected from heating. The following phenomena were observed :—

Cathode Rays in the Open Air.

3. Cathode rays make the air glow faintly. A halo of bluish light surrounds the window; it is brightest near the window itself, but has no definite external limit; it does not extend further than 5cm. from the window. The light at each discharge appears to shoot in brushes in all directions from the window; it is not bright enough to be investigated by means of the pocket spectroscope. The window itself is dark while it is new. After some use it also begins to glow faintly, irregularly, only at a few points of the small surface; at some points a bluish-grey, at others merging into the green and the yellow. Once started, this glowing appears regularly in the same manner. I shall refer again to this phenomenon, which is, however, an immaterial one.

4. Bodies capable of phosphorescing, if held near the window, glow on the side turned towards it with the light peculiar to them. Compared with the brilliant incandescence of the phosphides of the alkaline earths, of calc spar, and uranium glass, the light due to the air and the window disappears completely. With increasing distance from the window, the phenomenon quickly decreases in intensity, disappearing at a distance of 6cm. or 8cm. The intensity of the incandescence is determined only by distance, direction being

All those bodies also remain dark, which are not capable of phosphorescence, such as metals, mica, gypsum crystals, sulphur crystals. All the specimens of quartz examined glowed blue, but only when held quite close to the window; a piece of rock salt behaved in the same way. It is evident that here we have the faintest cathode glows brought out. I have also noticed a faint blue light in the case of quartz in vacuum tubes.

In connection with the glowing of the window itself, much interest attached to aluminium oxide. An oxide, produced at aluminium cathodes, glowed faintly greyish-green and blue mixed, brightly only in a few points, *i.e.*, like the window. The assumption that this phosphorescence is due to a slight layer of oxide produced under the influence of cathode rays and ozone (*see* 6), is not contradicted by any subsequent observation.

Liquids, which up to the present were not susceptible to cathode rays, were as a rule not illuminated at all, or only feebly. This was seen in solutions of eosin, fluoresceïn, magdala red, sulphate of quinine, chlorophyll, all of which fluoresce well in daylight. These solutions, therefore, behave like eosin-gelatin. A mere drop of petroleum, attached to a wooden rod, showed its blue fluorescent light, and other fluorescent hydrocarbons behaved similarly. In the solid state the above named bodies also remained dark, with the sole exception of sulphate of quinine, which exhibited a brilliant blue colour.

Tubes of tinfoil or glass, introduced between the window and a phosphorescent body so that the line joining the two coincided with the axis of the tube, diminished rather than increased its light.

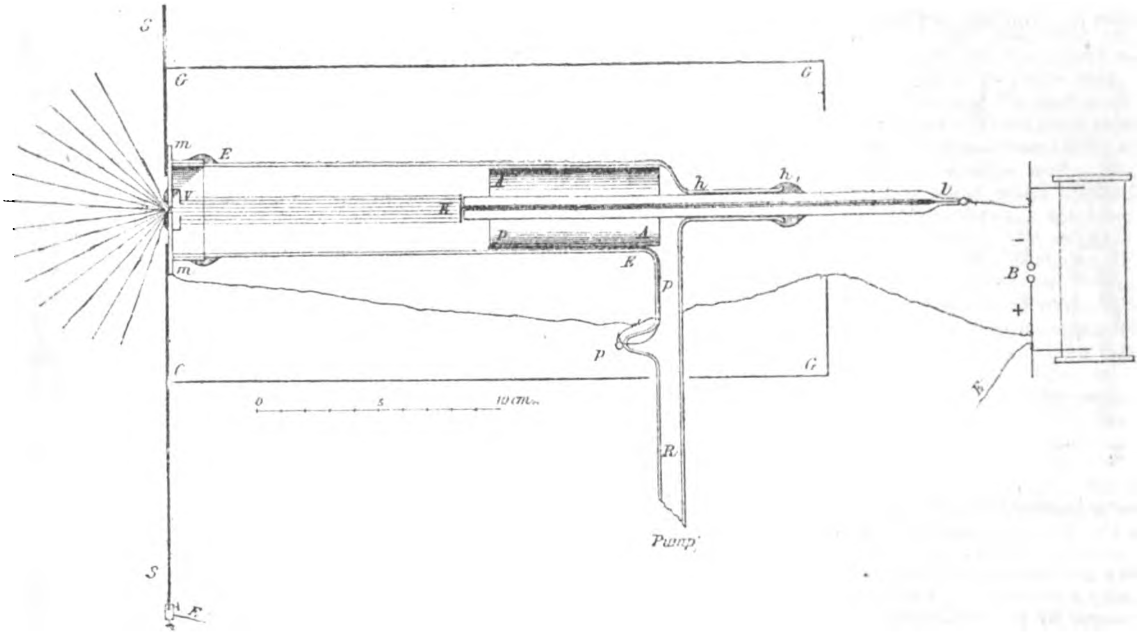

Fig. 1.

without influence. Thus the phosphorescence of a piece of calc spar is equally intense, whether it be placed at Φ (Fig. 2) or at Φ'. If a plane phosphorescent screen* be held perpendicularly against the window wall, so that its margin crosses the window, the brightness, dazzling near the window, decreases uniformly in all directions; equally bright points lie on semicircles whose centre is the window. This isotropic propagation from the window was to be expected from the fact that cathode rays penetrate aluminium diffusively.

The colour and relative brightness of illumination is the same in this case as that observed in vacuum tubes under the influence of cathode rays. Common glass, uranium glass, flint glass, calc spar, chalk, glow in their well-known manner; calc spar after-glows brightly. Very bright, with long after-glow, are the phosphides of the alkaline earths; not less bright, but without perceptible after-glow, pentadecylparatolylketone (green), and asaron (violet). A collection of platino-cyanides gave for the most part brilliant phenomena, the colour and brightness always corresponding to that observed in the ultra-violet solar spectrum; uranium glass yielded its characteristic line spectrum brightly. Eosin-gelatin, strongly phosphorescent in light, remained non-luminous, as in vacuum tubes.

* For this screen tissue paper soaked in pentadecylparatolylketone is specially suitable. The paper is laid upon a cold glass plate, and the melted substance is evenly spread with a brush. Such a screen is translucent, and may, therefore, be examined equally well from both sides; it glows much more brightly than uranium glass, without after-glow. By a phosphorescent screen, *per se*, we shall in future always mean a paper thus prepared; by a phosphorescent body a piece of strontium phospho sulphide attached to a wire and kept in the dark.

5. All phosphorescence phenomena in the observing space cease as soon as a magnet brought near the vacuum tube deflects the cathode rays from the window; the window itself and the air both remain dark.

6. Impinging on the skin, the cathode rays produce no sensation whatever, nor do they affect the eye. The nose perceives a strong smell of ozone, and the peculiar taste produced by the cathode rays upon the tongue may be also ascribed to ozone.

7. A quartz plate ½mm. thick, and not too small, when introduced at any point between the window and the phosphorescent body, extinguishes its glowing; common (genuine or imitation) gold, silver, or aluminium leaf allows it to remain without perceptible weakening. The quartz plate also intercepts the glowing of the air. Looking from above, one can see the air glow between the window and the quartz, but not behind the quartz. The metal films, however, do not cut off the glow of the air; it is very distinctly seen behind them, while the films themselves remain dark. The opacity of the quartz plates used and the transparency of the metal films are characteristic of cathode rays as contrasted with light. But we cannot conclude that quartz is more opaque to cathode rays than metals, considering the differences in thickness; metal plates ½mm. thick are as opaque as the quartz plates. I have altogether failed to find a solid of this thickness or thicker which is transparent. But all substances obtainable in thin films proved to be more or less transparent. Tissue paper placed on a phosphorescent screen only casts a distinct shadow when in a double layer, and it is indifferent whether the paper is coloured white, opaque black, or otherwise. Writing paper is already less trans-

Digitized by Google

parent, and a screen overlaid with drawing paper 0·12 mm. thick must be held quite close to the window in order to glow perceptibly. Cardboard 0·3mm. thick intercepted all luminosity. Blown glass films showed perceptible transparency already in thickness of 0·02mm., where they nearly equal the drawing paper mentioned. At a thickness of 0·01mm. they only cast faint shadows, and glass films showing Newton's colours are as transparent as double aluminium foil of equal thickness, or even more so. An essential difference between metals and dielectrics does not therefore exist. Finely split mica and collodion films, produced on a plane surface and drawn off, both about 0·01mm. thick, are very transparent. In the case of glass, and to exclude deception by its own vivid phosphorescence, an aluminium film was introduced between the glass and the phosphorescent body; or, better still, a phosphorescent screen was used, covered with aluminium foil and thus rendered once for all insensible to light. Such an aluminium cover turned towards the window does not diminish the glow of the screen, but increases it by reflection of the phosphorescence. But the water drops which attach the aluminium to the screen show as black spots. However, in sufficiently thin layers even an aqueous liquid is transparent. Soap films mounted in a wire ring only cast perceptible shadows when they exhibit colours of orders higher than the sixth, *i.e.*, when they are thicker than 0·0012 mm. The most surprising case of transparency remains that of metallic films. Starting from aluminium foil and proceeding to thicker plates we reach a highly tenacious rolled aluminium plate of 0·027 mm. thickness, which is just perceptibly transparent; the foil and the phosphorescent screen must, of course, now be held close to the window. In the same manner, *i.e.*, like the above drawing paper, were found to behave, thinnest iron foil and ordinary tinfoil, both 0·02mm. thick.

FIG. 2.

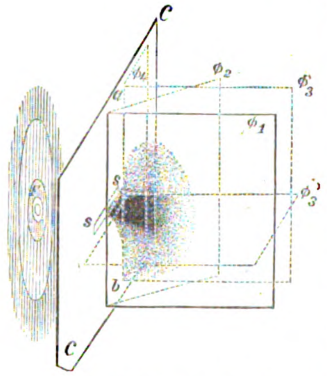

FIG. 3. (Natural Size.)

If two or more transparent screens are introduced between the window and the phosphorescent body—I tried a glass film, aluminium foil, and a gold film—it is immaterial to the glow in what succession they are interposed, provided they are large enough. In cases where only a small piece of the film to be tested was available, it was, for reasons to be presently (8) shown, either held close to the phosphorescent screen or close to the window, or it was stuck across an opening in a larger opaque screen.

A comparison between the above statements shows that no single one of the various bodies tested can be pronounced to be decidedly opaque or transparent in comparison with the others. In the case of light, one solid body a hundredth of a millimetre thick can be more opaque than another one meter thick; such vast differences do not appear to exist for cathode rays. The transparency of glass and collodion appears to contradict the observations of Crookes and Goldstein, according to whom even thin films of these bodies cast black shadows on to the wall of a vacuum tube. But it may be remarked, in the first instance, that the conditions of observations in discharge tubes are very unfavourable. In the flood of light it is impossible to say whether the shadow behind a transparent body is or is not perfectly dark, and this may partly account for the fact that the transparency of opaque metals was the first to be discovered. In the second place, it is not impossible—it is, indeed, probable—that the observers referred to produced under different circumstances different kinds of cathode rays, which are less able to penetrate matter than those here used, which are not only suitably produced, but are filtered by the window.

On replacing the aluminium window by one of glass it was found possible to repeat all the essential experiments with equal success. But the aluminium window remains the more suitable; not that it is more transparent, but because aluminium is opaque to light, and more easily manipulated than glass of equal thickness.

8. The atmosphere is a turbid medium for cathode rays; they are not propagated rectilinearly, but diffused. If a phosphorescent screen is placed parallel to the window wall, say at a distance of 3cm., and an opaque screen, say a quartz plate ½mm. thick, is slowly introduced midway between window and screen, we only see a very indistinct shadow outline on the screen. On fixing the quartz plate in position, and marking on the screen the line in which it is cut by a plane through the window and the edge of the quartz, it is seen that the luminosity overlaps by about 1cm. into the geometrical shadow of the quartz plate thus obtained. If we approach the quartz plate to the screen, this overlapping is diminished, and the shadow is better defined; at 3mm. distance it is still rather indistinct; it only becomes perfectly definite when the plate touches the screen. In the same manner a wire 2mm. thick does not cast an equally large, pretty well marked, and black shadow until it touches the screen. On removing it thence towards the window the shadow is immediately illuminated, and becomes very indefinite; it disappears completely when the wire is 3mm. from the screen. The cathode rays therefrom strongly bend round the edges of opaque bodies. Deception by the illuminated air is excluded, since if we cover the screen with aluminium foil nothing is altered. The quartz plate may be employed to show that our conception of all effects as proceeding from the small window is correct. For if we pass the edge quite close in front of the window, the darkening of the screen begins at the first contact with the window margin, and is just completed at the second contact.

As we have just seen, it is impossible to separate by diaphragms definite rays of even a centimetre's length. If we place a metal plate with a sharp cut hole, 1mm. across, at a distance of about 2cm. from the window, we find a sharp, bright, and equally large image of this hole, only quite close behind the aperture; already at 3mm. the image is magnified about five times and ill-defined, at 8mm. it is magnified ten times, at 12mm. very indefinite and much more magnified.

Fig. 3 shows this distribution at a glance, as produced by a slit, *s s*, 15mm. long and 2mm. broad, cut in the cardboard C C and placed at a distance of 12mm. from the window, F. The ketone screen Φ_1 is held to the slit so as to have the window in its plane. The bushy expansion of the rays is very distinctly shown here, brightness being as faithfully as possible represented by intensity

FIG. 3a.

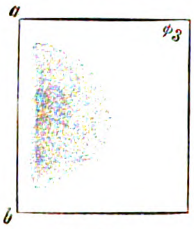

FIG. 3b.

(Natural Size.)

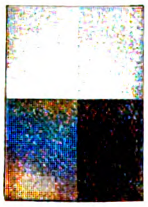

FIG. 4.

of black. On inclining the screen to the position Φ_2, at 45deg. to the plane of the slit, we obtain Fig. 3*a*. We notice here, more distinctly than in the last position, that a fraction of the rays does proceed in straight lines, just as in the case of light through dilute milk, in which we may see diffused light and sharp images. In the first position of the screen the straight rays could not become prominent, since they were propagated tangentially to the screen. When the screen is held on one side of the slit, Φ_3 or Φ_3^1 (Fig. 3), we get an appearance resembling Fig. 3*b* (for the position Φ_3). This is maintained when screen and slit are displaced in the plane of the latter into a position in which rectilinear rays can no longer reach the screen. The bushy expansion shown in Fig. 3 corresponds then to the actual state of things, and is not conditioned or impeded by the presence of the screen Φ_1. Finally, if we turn the screen from the position Φ_3 about its edge *a b* into the position Φ_4, so that it coincides with the slit screen, it remains perfectly dark. Hence no rays bend backwards; again in agreement with Fig. 3.

If parallel rays are allowed to pass through a short vertical slit of 1mm. breadth into a plane parallel trough filled with milk, so that the beam pass through the upper strata of the milk, the beams, as observed from above, are seen to expand from the narrow entrance in exactly the same way as the cathode rays in Fig. 3. Even the trace of rectilinear rays is there. On immersing the slit in the milk the phenomenon remains the same, and the analogy with the cathode ray experiment is more complete.

9. Cathode rays are photographically active. Sensitive printing paper held near the window is blackened at about the same rate as by the subdued sunshine of a foggy day; behind a quartz plate it remains unaffected. Dry plates with development are perfectly blackened at greater distances in a few seconds. The phosphorescent screen may therefore be replaced by the photographic plate. Fig. 4 is the copy of an image thus obtained. In this case the sensitive layer was, as shown in Fig. 4A, half-covered with a quartz plate, Q Q, ⅓mm. thick, across which was laid the double aluminium plate, A L. If light had been the agent, the appearance of the copy must have resembled Fig. 4A. Fig. 4 is very different from this. Not the aluminium plate,

Digitized by Google

but the quartz plate has cast the black shadow. In the fourth quadrant this shadow is slightly relieved ; this is due to the light of the air ; the effect is quite absent in the third quadrant, which is covered both with quartz and aluminium. A very much stronger effect than that due to light is produced by the cathode rays, as shown in the upper half of Fig. 4. A shadow of the double aluminium film is only faintly indicated in quadrant II. On the whole, Fig. 4 is nothing but a faithful representation of the phenomena exhibited directly by a phosphorescent screen. But the photographic plate can bring to light effects otherwise imperceptible, provided the exposure be long enough. Thus a pretty strong blackening was obtained behind the cardboard screen 0·3mm. thick, described above (7) as impervious. The cardboard covered the sensitive layer, and strips of different metals were introduced between both. These strips appeared quite in accordance with their degree of transparency lighter (in the negative) on a darker ground, and the film only remained perfectly light where a thick metal frame was laid over all. So cathode rays had actually penetrated through the thick cardboard. Exposure was only two minutes.

Iodine paper turned blue in the observing space ; covered with quartz it remained unaltered. It is doubtful whether this is the direct chemical effect of the ozone developed, or the effect of the ozone generated by them (6). Other chemical effects I have not observed. Electrolytic oxy-hydrogen gas, impinging upon the window or permeated in a thin soap-bubble, did not explode. Carbon bisulphide was not ignited. Even the easily decomposed hydrogen sulphide remained unaffected by a prolonged exposure to the rays in a glass tube attached to the window wall, no sulphur deposit being discernible. A mixture of 3 volumes hydrogen and 1 volume nitrogen, contained in a similar tube containing some water and communicating with a capillary tube with alcohol gauge, showed no decrease in volume, and hence no formation of ammonia. But in this case, as well as in that of air, carbonic acid, or hydrogen, a small increase of volume was observed, which disappeared (somewhat irregularly) after exposure, probably due to the heating of the gases by the absorbed cathode rays. To judge by the amount of expansion this heating would be very slight.* A delicate ther-

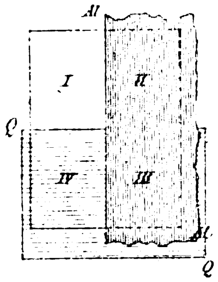

Fig. 4a.

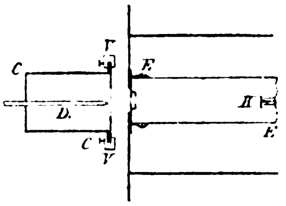

Fig. 5.

mometer and a thermopile placed at the window gave accordingly no definite indications of heat. The effect of a candle flame 50cm. off was easily discovered by means of the thermopile used. The energy of our cathode rays might thus appear to be very feeble, if we lost sight of the fact that the radiation is limited to extremely short time-intervals.

10. Cathode rays penetrate into the interior of spaces closed metallically ; they are perfectly divisible from the electric forces producing them. Up to now we have allowed the cathode rays to enter the observing space through the conducting window wall put to earth ; it was protected from the electric forces of the discharge (2), but, as is seen, not perfectly so. With any conductor in the observing space small sparks may be drawn from the screen (S, Fig. 1), and the same may be done with aluminium foil permeated by the rays. But these sparks remain the same when a magnet (5) applied to the discharge tube deflects the cathode rays from the observing space. This shows that the electric forces producing the sparks have no immediate connection with the cathode rays. It might be expected that the sparks would disappear, and the cathode rays remain, if the whole discharge apparatus were enclosed in a conducting envelope adjoining the window wall. It is easier in practice to reverse the process, and to exclude the whole generating apparatus by means of a perfectly closed conducting envelope. The well-soldered tin box, C C, Fig. 5, is placed as such an envelope at the window. The removable front partition, V V, is a metal frame with an opening 4cm. square, covered with aluminium foil 0·0045 thick (double the thickness of the window). Into this box the cathode rays enter quite as easily as if only its front wall were present. This may best be shown by enclosing a photographic plate in it. The negative of Fig. 4 was actually obtained in this box, and was indistinguishable from others taken in the open observing space. Fig. 4 shows especially that the luminosity of the air also exists in the box, that it therefore does not appertain to the electric forces, but to the cathode rays. If we now replace a portion of the wall of the box by fine wire gauze soldered to it, this luminosity and the phosphorescence of bodies inside may be directly observed. But it is quite impossible to draw with a pointed wire, D (Fig. 5), even the smallest spark out of the front wall inside the box, whether the wire is connected with the back wall or not. Only when in the latter case the wire is prolonged outward a few centimetres, does it give sparks with the front wall ; but in this case the electric forces are introduced from behind into the box by the insulation of the wire.

It is, therefore, possible to completely separate the cathode rays from the electric forces (in the narrower sense). This excludes the assumption that the window or other surfaces, which we have designated as pervaded by the rays, act as cathodes in the ordinary sense. Again, the back of such a surface only sends out rays from those places which correspond to those illuminated from the front, as shown by the shadows of wires and quartz plates propagated through aluminium foil (8). To make cathode rays of the observed lengths proceed in all directions from the back of a plate in air, or, generally, to make cathode rays in a perfect vacuum (see below) proceed in that way, can only be done in the known way, viz., by allowing cathode rays to fall upon the front of the plate.

11. Electrified bodies lose their charge in the observing space. An insulated metal plate placed near the window, say an aluminium disc 17mm. in diameter, does not, when exposed to the rays, acquire any charge which might be discovered by a sensitive Exner electroscope. But if the plate, to begin with, was given a positive or negative charge, the leaves of the electroscope collapsed immediately when exposure took place. The state of things was unaltered when plate and electroscope were surrounded by a cage of very fine wire gauze in contact with the window wall. The much used ½mm. quartz plate intercepts this effect when applied to the window, but not till it just completely covers the window. Aluminium foil transmits the effect. Intercepting the cathode rays by a sufficiently strong magnet applied to the discharge tube stops the effect. On removing the aluminium disc to 8cm. from the window, that is to the limit of perceptible displays of phosphorescence, the effect is not much diminished ; it is shown very distinctly even at a distance of 30cm. from the window. The introduction of the hand midway between window and plate intercepts them. The sudden discharge of the plate near the window may be slightly retarded by the addition of a Leyden jar of medium size. I have also noticed the discharging effect in rarified air. It is not decided whether this was an influence of the cathode rays upon the surface of the window, or upon the air, or upon the irradiated plate itself. The latter supposition seems hardly probable considering the great distances.

(To be continued.)

* The tube, centrally attached to the window wall, was 6cm. long and 4·5cm. wide inside, so that the chief portion of the cathode rays was absorbed in the enclosed gas and only little at the walls. The tube contained 95·4 cubic cm. of gas ; the increase of volume attained 25 cubic mm., which would only mean a heating through 0·08°C.

THE BOARD OF TRADE ELECTRIC TRACTION REGULATIONS.

Various Acts of Parliament and Provisional Orders granted last Session, authorising the use of electric traction on tramways, impose on the Board of Trade the duty of prescribing regulations to be observed by the tramway companies for the prevention of injury to gas and water pipes, and for minimising interference with other electric circuits. After hearing the various parties interested the Board of Trade have decided to prescribe regulations in the accompanying form. The regulations as originally drafted will be found in *The Electrician* of November 24, 1893, p. 96.

Definitions.

In the following regulations—

The expression "energy" means electrical energy.

The expression "generator" means the dynamo or dynamos or other electrical apparatus used for the generation of energy.

The expression "motor" means any electric motor carried on a car and used for the conversion of energy.

The expression "pipe" means any gas or water pipe or other metallic pipe, structure or substance.

The expression "wire" means any wire or apparatus used for telegraphic, telephonic, electrical signalling, or other similar purposes.

The expression "current" means an electric current exceeding one thousandth part of one ampere.

The expression "the Company" has the same meaning as in the Tramways Act.

Digitized by Google

Regulations.

1. Any dynamo used as a generator shall be of such pattern and construction as to be capable of producing a continuous current without appreciable pulsation.*

2.—One of the two conductors used for transmitting energy from the generator to the motors shall be in every case insulated from earth, and is herein-after referred to as the "line"; the other may be insulated throughout, or may be uninsulated in such parts and to such extent as is provided in the following regulations, and is herein-after referred to as the "return."

3. Where any rails on which cars run or any conductors laid between or within 3ft. of such rails form any part of a return, such part may be uninsulated. All other returns or parts of a return shall be insulated, unless of such sectional area as will reduce the difference of potential between the ends of the uninsulated portion of the return below the limit laid down in Regulation 7.

4. When any uninsulated conductor laid between or within 3ft. of the rails forms any part of a return, it shall be electrically connected to the rails at distances apart not exceeding 100ft. by means of copper strips having a sectional area of at least one-sixteenth of a square inch, or by other means of equal conductivity.

5. When any part of a return is uninsulated it shall be connected with the negative terminal of the generator, and in such case the negative terminal of the generator shall also be directly connected, through the current-indicator herein-after mentioned, to two separate earth connections which shall be placed not less than 20 yards apart.

Provided that in place of such two earth connections the Company may make one connection to a main for water supply of not less than 3in. internal diameter, with the consent of the owner thereof and of the person supplying the water, and provided that where, from the nature of the soil or for other reasons, the Company can show to the satisfaction of an inspecting officer of the Board of Trade that the earth connections herein specified cannot be constructed and maintained without undue expense the provisions of this regulation shall not apply.

The earth connections referred to in this regulation shall be constructed, laid, and maintained so as to secure electrical contact with the general mass of earth, and so that an electro-motive force, not exceeding four volts, shall suffice to produce a current of at least two amperes from one earth connection to the other through the earth, and a test shall be made at least once in every month to ascertain whether this requirement is complied with.

No portion of either earth connection shall be placed within 6ft. of any pipe except a main for water supply of not less than 3in. internal diameter which is metallically connected to the earth connections with the consents herein-before specified.

6. When the return is partly or entirely uninsulated the Company shall in the construction and maintenance of the tramway (*a*) so separate the uninsulated return from the general mass of earth, and from any pipe in the vicinity; (*b*) so connect together the several lengths by the rails; (*c*) adopt such means for reducing the difference produced by the current between the potential of the uninsulated return at any one point and the potential of the uninsulated return at any other point; and (*d*) so maintain the efficiency of the earth connections specified in the preceding regulations as to fulfil the following conditions, viz.:—

(i.) That the current passing from the earth connections through the indicator to the generator shall not at any time exceed either two amperes per mile of single tramway line or five per cent. of the total current output of the station.

(ii.) That if at any time and at any place a test be made by connecting a galvanometer or other current-indicator to the uninsulated return and to any pipe in the vicinity, it shall always be possible to reverse the direction of any current indicated by interposing a battery of three Leclanché cells connected in series if the direction of the current is from the return to the pipe, or by interposing one Leclanché cell if the direction of the current is from the pipe to the return.

In order to provide a continuous indication that the condition (i.) is complied with, the Company shall place in a conspicuous position a suitable, properly connected, and correctly marked current-indicator, and shall keep it connected during the whole time that the line is charged.

The owner of any such pipe may require the Company to permit him at reasonable times and intervals to ascertain by test that the conditions specified in (ii.) are complied with as regards his pipe.

7. When the return is partly or entirely uninsulated a continuous record shall be kept by the Company of the difference of potential during the working of the tramway between the points of the uninsulated return furthest from and nearest to the generating station. If at any time such difference of potential exceeds the limit of seven volts, the Company shall take immediate steps to reduce it below that limit.

8. Every electrical connection with any pipe shall be so arranged as to admit of easy examination, and shall be tested by the Company at least once in every three months.

9. Every line and every insulated return or part of a return except any feeder shall be constructed in sections not exceeding one-half of a mile in length, and means shall be provided for isolating each such section for purposes of testing.

10. The insulation of the line and of the return when insulated, and of all feeders and other conductors, shall be so maintained that the leakage current shall not exceed one-hundredth of an ampere per mile of tramway. The leakage current shall be ascertained daily before or after the hours of running, when the line is fully charged. If at any time it should be found that the leakage current exceeds one-half of an ampere per mile of tramway the leak shall be localised and removed as soon as practicable, and the running of the cars shall be stopped unless the leak is localised and removed within 24 hours. Provided that where both line and return are placed within a conduit this regulation shall not apply.

11. The insulation resistance of all continuously-insulated cables used for lines, for insulated returns, for feeders, or for other purposes, and laid below the surface of the ground, shall not be permitted to fall below the equivalent of 10 megohms for a length of one mile. A test of the insulation resistance of all such cables shall be made at least once in each month.

12. Where in any case in any part of the tramway the line is erected overhead and the return is laid on or under the ground, and where any wires have been erected or laid before the construction of the tramway in the same or nearly the same direction as such part of the tramway, the Company shall, if required so to do by the owners of such wires or any of them, permit such owners to insert and maintain in the Company's line one or more induction coils or other apparatus approved by the Company for the purpose of preventing disturbance by electric induction. In any case in which the Company withhold their approval of any such apparatus the owners may appeal to the Board of Trade, who may, if they think fit, dispense with such approval.

13. Any insulated return shall be placed parallel to and at a distance not exceeding three feet from the line when the line and return are both erected overhead, or 18 inches when they are both laid underground.

14. In the disposition, connections, and working of feeders the Company shall take all reasonable precautions to avoid injurious interference with any existing wires.

15. The Company shall so construct and maintain their system as to secure good contact between the motors and the line and return respectively.

16. The Company shall adopt the best means available to prevent the occurrence of undue sparking at the rubbing or rolling contacts in any place and in the construction and use of their generator and motors.

17. In working the cars the current shall be varied as required by means of a rheostat containing at least 2) sections, or by some other equally efficient method of gradually varying resistance.

18. Where the line or return or both are laid in a conduit the following conditions shall be complied with in the construction and maintenance of such conduit:—

(*a.*) The conduit shall be so constructed as to admit of easy examination of and access to the conductors contained therein and their insulators and supports.

(*b.*) It shall be so constructed as to be readily cleared of accumulation of dust or other *débris*, and no such accumulation shall be permitted to remain.

(*c.*) It shall be laid to such falls and so connected to sumps or other means of drainage, as to automatically clear itself of water without danger of the water reaching the level of the conductors.

(*d.*) If the conduit is formed of metal, all separate lengths shall be so jointed as to secure metallic continuity for the passage of electric currents. Where the rails are used to form any part of the return they shall be electrically connected to the conduit by means of copper strips having a sectional area of at least one-sixteenth of a square inch, or other means of equal conductivity, of distances apart not exceeding 100 feet. Where the return is wholly insulated and contained within the conduit, the latter shall be connected to earth at the generating station through a high resistance galvanometer suitable for the indication of any contact or partial contact of either the line or the return with the conduit.

(*e.*) If the conduit is formed of any non-metallic material not being of high insulating quality, and impervious to moisture throughout, and is placed within 6ft. of any pipe, a non-conducting screen shall be interposed between the conduit and the pipe, of such material and dimensions as shall provide that no current can pass between them without traversing at least 6ft. of earth, or the circuit [conduit ?] itself shall in such case be lined with bitumen or other non-conducting damp-resisting material in all cases where it is placed within 6ft. of any pipe.

(*f.*) The leakage current shall be ascertained daily, before or after the hours of running, when the line is fully charged, and if at any time it shall be found to exceed half an ampere per mile of tramway the leak shall be localised, and removed as soon as practicable, and the running of the cars shall be stopped unless the leak is localised and removed within 24 hours.

19. The Company shall, so far as may be applicable to their system of working, keep records as specified below. These records shall, if and when required, be forwarded for the information of the Board of Trade.

Daily Records.

Number of cars running.
Maximum working current.
Maximum working pressure.
Maximum current from the earth connections (*vide* Regulation 6 (i.)).
Leakage current (*vide* Regulations 10 and 18 (*f.*)).
Fall of potential in return (*vide* Regulation 7).

Monthly Records.

Condition of earth connections (*vide* Regulation 5).
Insulation resistance of insulated cables (*vide* Regulation 11).

Quarterly Records.

Conductance of joints to pipes (*vide* Regulation 8).

Occasional Records.

Any tests made under provisions of Regulation 6 (ii.).
Localisation and removal of leakage, stating time occupied.
Particulars of any abnormal occurrence affecting the electric working of the tramway.

March 6, 1894. Board of Trade, 7, Whitehall-gardens, S.W.

* The Board of Trade will be prepared to consider the issue of regulations for the use of alternating currents for electrical traction on application.

BOARD OF TRADE (DRAFT) REGULATIONS FOR UNDERGROUND ELECTRIC RAILWAYS.

Certain Acts of Parliament granted last Session, authorising the use of electric traction on railways to be constructed underground in metal-lined tunnels, impose on the Board of Trade the duty of prescribing regulations for the prevention of injury to gas and water pipes, and for minimising interference with other electric circuits. The following draft regulations have been prepared, and submitted for the consideration of the Board of Trade:—

Definitions.

In the following regulations—

The expression "energy" means electrical energy.

The expression "generator" means the dynamo, or dynamos, or other electrical apparatus used for the generation of energy.

The expression "motor" means any electric motor carried on a train and used for the conversion of energy.

The expression "pipe" means any gas or water pipe, or other metallic pipe, structure, or substance.

The expression "the Company" has the same meaning as in the Railway Act.

Regulations.

1. Any dynamo used as a generator shall be of such pattern and construction as to be capable of producing a continuous current without appreciable pulsation.*

2. One of the two conductors used for transmitting energy from the generator to the motors shall be in every case insulated from earth by means of insulators of a strong and durable material, so shaped as to offer great resistance to surface leakage, and is hereinafter referred to as the "line"; the other may be similarly insulated throughout, or may be uninsulated in such parts and to such extent as is provided in the following regulations, and is hereinafter referred to as the "return."

3. Where any rails on which trains run or any conductors laid within the metal-lined tunnels in which the railway is constructed form any part of a return, such part may be uninsulated. All other returns or parts of a return shall be insulated.

4. When any uninsulated conductor forms any part of a return, it shall be electrically connected to the rails at distances apart not exceeding 100 feet by means of copper strips having a sectional area of at least one-sixteenth of a square inch, or by other means of equal conductivity.

5. When any part of a return is uninsulated it shall be connected with the negative terminal of the generator and in such case the negative terminal of the generator shall also be directly connected to the iron or other metal plates forming the lining of the tunnels. In each case the connection shall be made through a suitable current indicator.

6. The iron or other metal plates forming the lining of the tunnels shall be so made and connected together as to form a continuous metal tube.

7. Where any pipe is brought into the tunnel from outside, means shall be provided to secure that no portion of the pipe outside the metal tube shall be in metallic connection with the tube or with any conductor of electricity within the tube.

8. When the rails form any part of the return they shall either be electrically connected, at intervals not exceeding 100ft., to the metal tube by metallic conductors which will not be appreciably heated by a current of 100 amperes, or they shall not be in any metallic connection with the metal tube except by means of the connections to the negative terminal of the generator. In the latter case the rails shall be supported by cross sleepers of wood specially prepared to resist the penetration of moisture and the growth of any mould or fungus, and they shall be of such sectional area and so connected at joints and from one line of rails to another, and where necessary to supplementary conductors or feeders, that the difference of potential between the rails and the metal tube shall not in any part and under any working conditions exceed 10 volts. A test of this shall be made at least once in each month.

9. When the return is partly or entirely uninsulated a continuous record shall be kept by the Company of the difference of potential during the working of the railway between the points of the uninsulated return furthest from and nearest to the generating station. If at any time such difference of potential exceeds the limit of seven volts, the Company shall take immediate steps to reduce it below that limit.

10. Every line and every insulated return shall be constructed in sections, and means shall be provided at or near each station for breaking the connection between sections for the rapid localisation of faults.

11. The insulation resistance of any conductor laid outside the metal tube shall not be permitted to fall below the equivalent of 10 megohms for a length of one mile. A test of this shall be made at least once in each month

12. The leakage current shall be tested daily before and after the hours of running with the working pressure, and duly recorded. Should the amount of this at any time appear to indicate a fault of insulation, steps shall at once be taken to localise and remove it.

13. The Company shall, so far as may be applicable to their system of working, keep records as specified below. These records shall, if and when required, be forwarded for the information of the Board of Trade.

Daily Records.

No. of trains running.
Maximum working current.
Maximum working pressure.
Maximum current from the rails to generator.
Maximum current from the metal tube to generator.
Leakage current (*vide* Regulation 12).
Fall of potential in return (*vide* Regulation 9).

Monthly Records.

Maximum difference of potential between rails and metal tube (*vide* Regulation 8).
Insulation resistance of conductors laid outside metal tube (*vide* Regulation 11).

Occasional Records.

Localisation and removal of leakage, stating time occupied.
Particulars of any abnormal occurrence affecting the electric working of the railway.

* The Board of Trade will be prepared to consider the issue of regulations for the use of alternating currents for electrical traction on application.

Note.—Those regulations only apply to railways constructed underground in metal-lined tunnels.

REVIEWS.

The Book of the Fair. Parts 10 and 11. (The Bancroft Company, Chicago and San Francisco.)

To commemorate and to record the wonders of the Chicago Exhibition an elaborately-illustrated book is being published in parts. Lest words should fail us in singing its praises, 17 ready-made suggestions for reviews accompany the two parts which we have received. We search in vain for any useful information, statistics, scientific tests of machinery or apparatus, or anything which we can commend to our readers, but are only met by columns of extracts from exhibitors' catalogues, interspersed with this sort of thing: "Let us imagine ourselves standing at eventide in the central court, now almost a solitude, haunted by the shadows of deserted temples cast athwart the plaza." This reminds us, by the way, that the innumerable photographs which we have seen of the grounds and buildings of this Exhibition are remarkable for the small number of visitors; perhaps, for the sake of quiet, they were taken on Sundays. The electrical section of this book contains only one reproduction of an out-door photograph, and in this not a single human being is visible. In the agricultural section, a portion of which is to be found in Part 10, a view of the administration plaza on "Chicago Day" amply makes amends for this deficiency. The illustrations of the exhibitors' stalls are remarkably fine specimens of photographic reproduction, and do as great credit to the printers as did, at the time, the woodcuts in the similar volumes recording the London Exhibition of 1851.

Standard Tables for Electric Wiremen. By C. M. Davis. Fourth edition; revised and edited by W. D. Weaver. (New York: W. J. Johnston Co.)

In this compact little work we have a collection of tables, rules and diagrams, which may be considered likely to be of use to a wireman. The data are based upon American practice, however, which differs in many respects from English practice; and the tables are all referred to the B and S wire gauge, quite unknown over here.

Induction Coils and Coil-Making. By F. C. Allsop. (London: E. and F. N. Spon. New York: Spon and Chamberlain. 1894.)

The scope of this little book is restricted to the construction and action of shocking, medical and spark induction coils, and their accessories. Those who are desirous of learning how to make or use a coil will find full particulars in this little treatise, which is copiously illustrated with not very superior cuts. A portion of the book has already appeared as a series of articles in the *English Mechanic*. Not a word is to be found about the very simple oil coils, with which the brilliant experiments of Tesla, Elihu Thomson, Swinton, and others can be so easily carried out.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

THURSDAY, March 29th.

Institution of Electrical Engineers.

8 p.m. General Meeting at 25, Great George-st. Presentation of balance-sheet. The following Paper will be further discussed: "Parallel Working through Long Lines," by W. M. Mordey, Member; to be followed by the reading of the following Papers: (1) "A Universal Shunt Box for Galvanometers." (2) "Transparent Conducting Screens for Electric and other apparatus." (3) "An Astatic Station Voltmeter," by Prof. W. E. Ayrton, F.R.S., and T. Mather. (4) "The Best Resistance for the Receiving Instrument with a leaky telegraph line," by Prof. W. E. Ayrton and C. S. Whitehead, M.A.

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of*—

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.
The same book in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRIC MOTIVE POWER. By A. T. SNELL. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

PRACTICAL MAGNETISM. By J. A. KINGDON. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK FOR 1894.

(THE BIG BLUE BOOK.)

1,000 pages of valuable information; 550 closely-printed pages of Directory matter.

Price 7/6, post free 8/3; abroad 8/10.

ELECTRIC TRAMWAY REGULATIONS.

The amended regulations by the Board of Trade for the employment of insulated or uninsulated returns of electric tramways have been issued and will be at once incorporated in the various Acts of last session. In order to save our readers the trouble of referring to the draft form of these regulations, we print them in full in their final form in another column. We have compared the two copies, word by word, and in scarcely a single instance can the interests of electric traction be said to have suffered by the amendments made after and in consequence of the Conference at which the matter was so fully discussed. We have also received a draft copy of the regulations which are intended to apply to railways constructed underground in metal-lined tunnels. These are also printed in full in another column. The fact that such a line is surrounded by a cast-iron tube which may be made electrically continuous throughout its length, rather than that it is a railway as distinguished from a tramway, makes further regulations necessary, but at the same time this fact considerably simplifies the matter.

The general effect of the regulations is to compel the use of feeders, and although the use of such conductors has been the exception rather than the rule in this country, it must be remembered that most of our lines have been experimental, or of limited length. Considerations of economy of power, quite as much as possibility of electrolytic corrosion, will be sufficient in most cases to induce traction engineers to use feeders, and the tapping of the return which, whether insulated or uninsulated, is really a feeder, at distances not exceeding 100 feet

Digitized by Google

apart, will not be a very expensive matter. The most important electric line in this country, and no mere tramway, but perhaps the most important electrical railway in the world, namely the Liverpool Overhead Railway, has no feeders, nor has it, indeed, copper conductors. The conductor is of steel and the return is by the rails and perhaps also by the iron structure. The specific resistance of iron is greater than that of copper, approximately in the inverse ratio of the cost, and the fact that the sectional area in this case is four square inches does not imply that the conductor is so large that no feeders are required; the chief reason in this case is that the generating station being at the middle of its length, the line must for this purpose be considered as one of only about three miles.

In the first regulation the word "steady" has been omitted, and the words "without appreciable pulsation" have been introduced, the object being, of course, to avoid the use of such dynamos which give a fluctuating current. Prof. AYRTON has suggested the use of a "discontinuity meter," and it has been found that the fluctuations of current of a Brush machine amount to about 1½ per cent. Whether the current is found to present "appreciable pulsation" as specified in this regulation, will probably be settled merely by the presence or absence of any appreciable continuous hum in neighbouring telephone wires. There is, fortunately, no difficulty in avoiding this defect in ordinary dynamos, and the regulation is likely to be felt only where feeders supply the line by means of dynamotors, for here, there is a temptation to reduce the number of sections on the low-pressure commutator. The non-conducting screen mentioned in Regulation 5 was the subject of much discussion at the Conference. A layer of bitumen or coatings of bituminous paint will probably suffice; but it is to be hoped that the owners of gas and water pipes will soon recognise the simple scientific fact that their greatest security lies in ample connection with the earthed negative pole of the circuit. The alteration of Regulation 6 (i.) is of no little importance; the maximum earth current is increased from two amperes to ten per mile of single line, and a current equal to five per cent. of the total current output of the station is permitted, as an alternative. The specification of the direction of the current in 6 (ii.) is important. One of the main purposes of these regulations is to ensure that if any leakage or return current passes through the earth it shall *enter* gas and water pipes, and not leave them except through proper metallic conductors, thus avoiding corrosion. The allowance of fifteen per cent. increase in the fall of potential in regulation, instead of five volts as a limit, in Regulation 7, is one of the important concessions made at the Conference; and the localising and removal of leaks "as soon as practicable" in Regulation 10, and the taking "all reasonable precautions" in Regulation 14, are evidences of the liberal treatment which this matter has received at the hands of the Board of Trade.

Care has been taken to avoid the easy but unsatisfactory course of ordering that this, that, and the other, are to be done to the satisfaction of the Board of Trade. It is better to make a rather stringent rule and relax or qualify its enforcement, than to leave it in such a vague condition. At the same time, it must, of course, be acknowledged that the details of electric traction may be greatly developed, and that the rules must not tie down the practice to that of the present day, but must leave room for improvements. The sixteenth regulation affords an example. "The best means available" must be used to prevent "undue sparking at the rubbing or rolling contacts." When better means than the present ones are invented, this regulation will only entail a new kind of trolley wheel or head, or new brushes, or perhaps brush-holders. For such details as these we may look for assistance to America, although the general principles of our electric traction may be governed by the general conditions of this country. Considering that we have but one conduit line in this country, and one which is in many respects exceptional, and that the Buda-Pesth line, though successful, would not be tolerated here; the explicit terms of Regulation 18 may be said to refer to an ideal system rather than to any which is in actual use. Such a conduit has, indeed, to be invented, or, if invented but unknown, to be tried and worked on a practical scale. Some people look upon all regulations as hindrances, and regard them as Government interference with the liberty of individuals. That such rules are vexatious to some people cannot be denied, but investigation shows that the unrestricted doings of these people would be highly vexatious to the general public.

TESTING IRON OF TRANSFORMERS BY A WORKSHOP METHOD.

BY CLARENCE P. FELDMANN.

In 1886 Titus Otto Bláthy, of Budapest, wrote a letter to the Editor of *The Electrician*, telling him that he had succeeded in separating the hysteresis and eddy-current losses, and promising some further details in the near future. The letter was reproduced, but the promised details did not appear. The method consisted in observing for different voltages and different frequencies the total losses, and in putting the hysteresis losses proportional to the first, the eddy-current losses proportional to the second power of the frequency. Besides, the latter were taken proportional to the square of the induction, which Bláthy at that time called "magnetic current," and the power of B for the hysteresis losses was worked out by a method of trial and error. In the meantime Mr. Gisbert Kapp has taught us how to separate these losses for continuous-current dynamos, Dobrowolsky has employed this method for transformers, Steinmetz has given his empirical law, Evershed and Fleming have worked out the formulæ for the eddy-current losses occurring in the iron of transformers, and J. J. Thomson and Ewing have shown the mathematics of it. I have tried to find sufficiently exact formulæ for the eddy-current losses in iron sheets and iron wires, if thickness or diameter is measured in millimetres. Having found (from Fleming's values) the eddy-current loss per cubic centimetre, for sheets,

$$\left(\frac{b \cdot p \cdot \mathbf{B}_{max}}{2{\cdot}5 \times 10^6}\right)^2 \text{ watts,}$$

and for wires,

$$\left(\frac{b \cdot p \cdot \mathbf{B}_{max}}{2 \cdot \times 10^6}\right)^2 \text{ watts,}$$

where b = thickness or diameter in millimetres,

p = frequency, ∿ per second,

$\mathbf{B}_{max}$ = maximum induction.

I tried to verify these data by means of some of my own and Neustadt's and Bláthy's tests, the latter carried out in 1885 and 1886. The reasoning was the following:—The total losses had in both been measured by the Ganz wattmeter, the effective values of current and potential difference by means of an electro dynamometer and a cardew voltmeter. If I calculated the maximum induction $\mathbf{B}_{max}$ from the effective value of the potential difference $\mathbf{B}_{max} = 0{\cdot}9\ E/4\ p.f.$ where E = effective potential difference, and f = sectional area, I could find the eddy-current loss per unit, and for the total volumes. Subtracting this loss, and the small loss due to the total magnetising current from the total loss measured by the wattmeter, I would obtain the hysteresis loss for the total and the unit volume. If this loss, divided by the 1·6th power of $\mathbf{B}_{max}$, gave a constant

Digitized by Google

number, the separation of eddy current and hysteresis losses was completed in the right way.

To make the calculation easier and less disagreeable I plotted the result in a curve, and picked out the values of the total losses for the following values of B_{max}:—

—	Total losses after subtraction of copper losses due to magnetising current.	Eddy-current losses calculated.	Consequently: Hysteresis losses observed.	Hysteresis losses calculated.	Difference in per cent.
B_{max} =	Watts.	Watts.	Watts.		
3,000	53·3	9·7	$45·6 = 1{,}245\ B_{max}^{1·6} \times 10^{-7}$ =	46·2	1·3
4,000	86·1	16·1	72·3 = 1,245 " × " =	73·0	1·0
5,000	124·8	25·0	103·3 = 1,245 " × " =	104·6	1·3
6,000	169·6	36·4	138·6 = 2,248 " × " =	140	1·0
7,000	221·7	50·3	179·5 = 1,262 " × " =	179	0·3
7,500	249·6	58·0	201·2 = 1,269 " × " =	200	0·6
			Mean value $1{,}255 \times 10^{-7} B_{max}^{1·6}$		1·0%§

§ Mean value.

The mean value of the difference between "observed" and "calculated" hysteresis losses—if those calculated from the observations as described may be called "observed" at all—is within the errors of observation. The observations were rather exact, as a very large number of them was made. The data refer to a transformer built up of iron sheets or strips 0·5mm. thick, 10mm. wide, and coiled up in the usual way of the old Ganz transformer to form plates whose magnetic length was 94cm. These iron plates were piled up so as to form a core of rectangular section, and the layers of the thin iron sheets or strips were separated by means of thin paper sheets. The other data were:—Sectional area of iron core, 129 sq. cm.; volume of core, 12,200 cubic cm.; number of windings, 30; resistance, 0·013 ohm; frequency, 42.

The calculated hysteresis losses were obtained from the relation $1255 \times 10^{-7} \times B_{max}^{1·6}$, which is equal to $42 \times 11200 \times 0·00245 \times 10^{-7} \times B_{max}^{1·6}$ watts.

Another series of observations, dated November 25, 1885, relates to a smaller transformer built of oxidised iron wire, one millimetre in diameter. The sectional area of the iron core was 30 sq. cm., the volume of the core was 1,320 cubic cm., the number of windings was 45, the resistance was 0·1 ohms, the frequency 54, and the length of the magnetic circuit was 42 cm.

Total indicated.	Total watts.	Calculated eddy current loss.	Observed hysteresis loss.	Calculated hysteresis loss.	Difference in %	a
B_{max} =						
7,000	36·5	11·8	24·7	24·7	0·0	0·00245
8,000	46·0	15·4	30·6	30·6	0·0	0·00244
9,000	56·0	19·5	36·5	36·9	1·1	0·00239
10,000	67·5	24·1	43·4	43·7	0·7	0·00240
11,000	80·0	29·2	50·8	50·7	0·2	0·00244
12,000	93·8	34·7	59·1	58·6	1·9	0·00248
				Mean value ...	0·5%	0·00244

The calculated hysteresis losses were in this case obtained from the relation $0·00244 \times 1320 \times 54 \times 10^{-7} \times B_{max}^{1·6}$ watts.

Having obtained these satisfactory results, I tried to push the thing a little further, and to find from the readings of the wattmeter, dynamometer, and Cardew voltmeter a magnetic characteristic of the transformers tested. To do this, I divided the total watts by the potential difference; this gave the one component of the total current as measured by the dynamometer. The second component was easily found by taking $\sqrt{(\text{total current})^2 - \left(\frac{\text{watts}}{\text{potential difference}}\right)^2}$. This second "wattless" component was the magnetising current, which gave the magnetomotive force, the magnetising force, and the permeability.

For the second transformer with iron wire core, the calculations gave:—

—	—	Watts : volts = amps.	$\sqrt{J^2_{tot} - J^2_{eff}}$	$H = \frac{45}{42} \cdot \frac{4\pi}{10} \cdot 0.9 J_0$	$\mu = \frac{B}{H}$
B_{max} =	J_{tot} =	J_{eff} =	J_0 = Amp.		
7,000	3·0	36·5 : 22·7 = 1·61	2·53	3·68	2,270
8,000	3·5	46·0 : 25·9 = 1·78	3·00	3·76	2,130
9,000	3·9	56·0 : 29·2 = 1·92	3·40	4·14	2,180
10,000	4·5	67·5 : 32·4 = 2·08	4·00	4·87	2,050
11,000	5·0	80·0 : 35·6 = 2·25	4·45	5·42	2,030
12,000	5·9	93·8 : 38·9 = 2·42	5·40	6·58	1,820

While, for the first transformer, a similar table contains the following numbers:—

—	—	Watts : volts = amps.	$\sqrt{J^2_{tot} - J^2_{eff}}$	$H = \frac{30}{91} \cdot \frac{4\pi}{10} \cdot 0.9 J_0$	$\mu = \frac{B}{H}$
B_{max} =	J_{tot} =	J_{eff} =	J_0 =		
3,000	4·70	53·3 : 21·6 = 2·47	4·0	1·49	2,010
4,000	5·67	86·1 : 28 8 = 2·99	4·82	1·79	2,230
5,000	6·58	124·8 : 36·1 = 3·45	5·60	2·08	2,400
6,000	7·50	169·6 : 43·3 = 3·92	6·39	2·38	2,520
7,000	8·41	221·7 : 50·6 = 4·38	7·17	2·67	2,620
7,500	8·90	249·6 : 54·1 = 4·62	7·63	2·84	2,640

Obviously, these results are not as trustworthy as those due to the wattmeter readings alone. This is due to the fact that the dynamometer was not sufficiently sensitive, and that the errors of the three observations enter in full into these results. But perhaps the method is worth mentioning for workshop use, as it gives the actual working data of the transformer, and for the frequency in question. If it is reversed it shows how to calculate the eddy current and hysteresis losses, and how to find from them the "wattless" component of the total current, the angle of lag between current and potential difference, and so on, as, among others, Dobrowlsky showed at his Frankfort lecture.

This is only one series of observations taken from Bláthy's exhaustive tests, which he carried out, together with L. Neustadt, in the autumn of 1885 and in the first months of 1886. Transformer cores of every description, with iron plates, wires, and strips of various sizes, were thoroughly tested; and, as has been said in another place, "it is a pity that this lot of useful material has been buried in the professional bosom."

ON PARALLEL WORKING, WITH SPECIAL REFERENCE TO LONG LINES.*

BY W. M. MORDEY.

(Concluded from page 557.)

SOME TESTS OF A 25-KILOWATT ALTERNATOR USED AS A MOTOR.

The motor in this case was arranged to drive a direct-current dynamo by means of which a load could be put on it that would be quite constant so long as speed was constant. It was desired—(*a*) To find the effect of placing in the alternator circuit various amounts of resistance; (*b*) to find the effect on the steadiness. The 25-kilowatt alternator motor was driven by a 50-kilowatt alternator as generator.

Test F.—Motor was run with no load except its own direct-coupled exciter, and the direct-current dynamo, which in this case was run unexcited.

EFFECT OF REDUCING MOTOR EXCITATION AS RESISTANCE IN EXTERNAL CIRCUIT WAS INCREASED.

A. Generator. Volts.	A. Motor. Volts.	Amperes.	Line Resistance.	Remarks.
2,000	2,000	2·23	0	Current varying a little.
1,980	1,900	3·7	0	Current very steady.
2,040	1,900	3·5	65	"
1,960	1,840	2·0	65	"
1,950	1,820	2·23	75	"
1,960	1,800	2·0	85	"
1,960	1,780	2·23	95	"
1,960	1,760	2·23	105	"

* Paper read before the Institution of Electrical Engineers, March 8.

Digitized by Google

We thus see a confirmation of what has been said about steady running being obtained, even with a very large resistance in the circuit, if there is a sufficient difference between volts of generator and motor. This is very common sense, and an experiment to prove it may seem superfluous. The experiment was not carried further, as the resistance used was the greatest available at the moment. This light load test should be read in connection with the full load test A.

Test G.—A test was then made with a load on the direct-current dynamo. This load was 8 kilowatts, and was constant. Allowing for friction, and various losses outside of itself, the alternator motor was doing between 14 h.p. and 15 h.p.

A. G'nerat'r Volts.	A. Motor. Volts.	Amperes.	Power dev'lop'd	Resist-ance.	Remarks.
2,040	2,040	7·0	14·5	0	Current fairly steady.
2,040	1,980	7·3	„	6	„ „
2,060	2,000	7·45	„	10	„ „
2,040	1,900	8·2	„	25	Current steadier.
2,040	1,740	9·8	„	35	Current steady.
2,120	1,540	11·0	„	45	„ „

In this is seen the gradual increase of motor current as the motor volts get lower, while steadiness rather improves with the addition of length (or resistance) of line. The test is incomplete, because it was not convenient to put a larger load on, and therefore the motor was not worked up to full power; but it is confirmatory of Test A. It is interesting to observe, with regard to this test, that the idle current was very small. For example, the first reading of 7 amperes may be divided into 2·25 amperes needed to drive the motor and its exciter, and for friction of the direct-current dynamo (see *Test F*); and into 4·75 amperes for the added load of 8 kilowatts. The dynamo gave 8 kilowatts, and the motor received about 4·75 amperes × 2,040 volts = 9,690 watts. Allowing for the losses in the two machines, it will be recognised that the transformation was not only very fairly efficient, but that the power-factor was evidently high.

The relative lowering of the E.M.F. of a synchronous motor is a necessity in order to obtain good results in power transmission over long distances. In this way the necessity for self-adjustment by the motor of the phase relation is avoided, the motor being enabled to work (other qualities permitting) at its most advantageous phase relation. And the other advantages are retained of high power-factor (that is, a small idle current) and a high efficiency of generator, motor, and line. By this means it will be found possible to work such motors over very long lines, and with almost any desired line loss. It, of course, has its counterpart in direct-current power transmission, but there is a difference. In one case the speed varies and the field remains constant, in the other the speed remains constant and the field must be varied. It is not necessary to alter the excitation of a direct-current motor—its speed simply drops or rises until it has got the right E.M.F. With an alternate-current synchronous motor the speed cannot drop. The excitation must be lowered in this case to give the right E.M.F. Failing this, the motor will shift its phase in an endeavour to attain the same result. Of course, in the direct-current machine, the speed may be kept up by lowering the field.

Some Tests of Two 100-Kilowatt Alternators.

Test H.—By the kindness of the City of London Company, I was enabled to make a trial with two of their 100-kilowatt alternators at Bankside, with the object of finding if, under the ordinary conditions of the station, these machines would work parallel with a considerable resistance between them and their load. For this purpose a load of about 100 kilowatts was put on, and the two alternators were made to supply it through a resistance of 7·5 ohms in the external circuit of each. As this resistance corresponds to 37·5 per cent. line drop at full load, and 18·75 per cent. drop at half load, it is a fairly severe test. It was found that some lamps and a voltmeter placed across the load (a wire resistance) kept perfectly steady. This, of course, was only a half-load test.

Test J.—When full load, or nearly full load, was on both machines, with 8 ohms in the circuit of each, there was a quite noticeable, but not at all violent, slow pulsation in the synchroniser lamp direct across the terminals of the alternators; but at the load the pulsation was very slight—barely noticeable. My impression was that with suitable adjustments this would have been quite a practicable arrangement—that is, to feed a lighting system from two alternators parallel, each having a 20 per cent. line loss between it and the load—a condition that is not likely to present itself very often.

Test K.—An attempt was then made to run the two machines parallel, with a load close to one of them, but separated from the other by a line of 16 ohms, corresponding to a line loss of about 40 per cent. The machines did not show any inclination to get out of step, but there was a pulsation of the E.M.F. at the lamps (at the load) of about 4 or 5 per cent. The result of this test, as carried out, was not good enough for lighting; although, if time and facilities had allowed, I think it quite likely that it could have been made satisfactory; but there was no pulsation or unsteadiness of a kind that would have interfered in any way with power transmission work.

It is a pleasure to me to make my acknowledgments to two assistants, Mr. Stobart and Mr. Foyster, who have ably aided me in connection with the recent tests and experiments, and to Mr. Watson in connection with the tests in 1891.

Some Analogies.

Probably I am not alone in having often found a difficulty in conveying, to persons not specially familiar with alternate-current matters, any very clear idea of the kind of action that takes place in parallel working. I would like, therefore, to be allowed to conclude by describing an analogy which I have often found useful in such cases.

Everybody knows something of toothed wheels. To explain the relations of two alternators, separately driven, working parallel, imagine two engines driving by spur gearing on to a common shaft. The shaft represents the circuit from which power may be taken; the spurs, or teeth, represent the successive waves of current. The operation of getting into synchronism is understood when one engine is imagined as running at its proper speed geared with the countershaft. To get the second engine to help, it will readily be understood that before being geared with the shaft it must be brought up to such a speed that the spurs of its toothed wheel synchronise with those on the shaft. A synchroniser, or phase-indicator, is the equivalent of a device for showing when the teeth of one wheel are exactly opposite the spaces between the teeth of the other wheel—that is, when they are synchronous. The mechanical process of slipping the two spur wheels together is the equivalent of electrically connecting the alternator and the circuit, and all the effects of doing this switching at the wrong time are easily illustrated by the sudden strain that would be imposed on the teeth. It will now be easy to follow the process of increasing the supply of steam to the engine until it transmits its proper proportion of power to the shaft; as well as the reduction of steam to such a point that the connection of either engine with the shaft (or of alternator with the circuit) can be interrupted at a time when no power is being transmitted from it or to it, and when, in consequence, its withdrawal makes no difference to the remaining engine (or alternator) or to the countershaft (or circuit). The changing of load from one engine to the other is readily understood.

Then the difficulties of parallel running may be made clear. Imagine one engine to get an insufficient supply of steam: it will be seen how the other must not only keep the countershaft (and any load) going, but must also drive the other engine. And note that this driven engine (receiving its power from the countershaft) is the analogue of the synchronous motor, and that the fact that the pressure is now not on the front side, but on the rear side, of the teeth, corresponds to the pull on the poles and armature coils being in the opposite direction to what it was as a generator; and that the difference of phase, or angle, between a generator and a motor, is illustrated by this change in the relative position of the teeth on spur wheel and shaft. If the teeth of one wheel are exactly midway between those of the other, corresponding to exact cophasal synchronism, a line drawn through the tip of one bisects the hollow of the other; and driving is possible either way, in this position, only if there is absolute fit—that is, no lag or lead—no clearance either side. As this is not possible in practice, there is always a lead or a lag, corresponding to similar changes in the relative positions of field and armature in an alternator, as generator and as motor; this change of angle being also conveniently expressed or measured in terms of the space occupied by a pair of teeth or a complete period.

Then it is possible, by this analogy, to get an engine builder to see what happens when an engine runs at different speeds during parts of each revolution. He will see that, if two engines are in use, and one is slowing a little as it goes over its dead centres, while the other is getting steam and quickening a little, the teeth of the former will be bearing with diminished pressure on the teeth of the countershaft, while the latter will be exerting increased pressure. And he will see that, if this difference is considerable, the power may all have to be supplied by one engine, which may even have to drive the other engine as well—that, in short, each engine may in each revolution be alternately a generator and a motor, twice or oftener (according to the number and setting of the cranks).

It will not be difficult to explain the pulsations of synchronising current transmitted through the circuit between the two alternators by the analogy of the impulses transmitted from one engine to another through the countershaft. He will also understand why, if the engines have this defect, this interchange of

Digitized by Google

power will not take place, and will not be required, if he so arranges matters that the connection is made at a time when the engines (supposing them arranged to run at the same speed) are in the same part of their stroke; but in this case, as the engines cannot correct each other's irregularities, the speed of the countershaft may have an objectionable want of evenness of running, affecting any machinery driven from the countershaft—that this difference will be less on the driven machinery if it is driven by belting, and therefore not necessarily synchronous, than if it is driven by spur gearing, and so forced to run at the same speed.

I will not stop to do more than suggest the comparisons that may usefully be drawn between weight of fly-wheel and of electromagnetic inertia or self-induction as illustrating the effects in steadying the running of all shafts or circuits. But I cannot resist the temptation to show that, as with alternators in parallel, the very rapid interchanges of power take place with scarcely perceptible resistance (that is, frictional) losses, it is conceivable that two such machines and engines will take less steam to drive them than if they are dividing the same load between them on separate circuits. That this increase in efficiency is a fact has been shown by actual tests, which I hope later on will be placed before you.

Then the analogy may be carried further, and an understanding may be imparted of the difference in the synchronising abilities of various alternators. To do this it is necessary to add to the analogy of spur gearing the idea of that gearing having teeth of various degrees of stiffness or rigidity, varying all the way from phosphor-bronze to yielding elastic material such as soft rubber. The former may be compared to the alternators having unyielding fields and small armature reaction; the latter to machines having poles the magnetism of which gives way, more or less, under pressure. It will, no doubt, be difficult to get the uninitiated to grasp the idea of a tuft of lines of magnetic force from a pole-piece acting, through air, on a copper wire carrying a current, as corresponding to the material teeth of spur wheels geared together; but it is at least worth the attempt, and the result is usually better than the antecedent chaos.

Having conveyed this idea of various degrees of rigidity of teeth, as the equivalent of the various degrees of synchronising efforts of which different alternators are capable, the next step is to explain why with alternators having magnetic teeth of the gelatinous variety it is possible to put them into parallel (or to gear them) when they are unsynchronous, without anything happening except a more or less complete temporary flattening of the teeth (or alternations) of both machines, corresponding to a temporary cessation of useful effort, until they have gradually worked themselves into phase. And it will be understood why with such machines any sudden alterations or strains should be avoided as likely to result in the bending down of the teeth and loss of synchronism. On the other hand, it will be seen that, if the machines have strong and unyielding teeth (or powerful synchronising qualities), they will make a prodigious effort to keep in step whatever happens. This analogy affords an explanation of the difference in the way in which the synchronising current circulates between alternators of the two kinds. With spur wheels of the strong type it will be seen that any transfer of power will be immediate and prompt, the correcting impulses being transmitted with decision and sharpness, the lagging or yielding permitted being only that due to the space between the teeth. This corresponds with the short, sharp impulses of synchronising current between two alternators of one type; while the slow and sluggish impulses of current between two alternators of the weak field type is understood by imagining what would happen with an attempted interchange of power between the two engines geared to a shaft by teeth of some yielding material.

A further analogy, and I have done, to show those who are at all familiar with the mechanics of spur gearing how unnecessary it ought to be, so far as the machines are concerned, to reduce the number of magnetic teeth, or periods, in order to get satisfactory and smooth driving, either singly or parallel. It is only in cases where the electrical spur wheels are so designed that the teeth cannot get in, that a small number of periods can be of any service (so far as the machinery is concerned). Steady and smooth driving is rather to be sought in the other direction.

DISCUSSION.

The following is an abstract of the discussion on Mr. Mordey's Paper. Speakers whose remarks are prefaced by an asterisk have returned their proofs revised:—

*Mr. RAWORTH said that the Brush Company had not by any means taken a very serious view of Prof. Forbes's statements. They were perfectly well aware that the dynamos they manufactured were not steam rollers or anything of that sort. They were manufactured to work under certain conditions, and they *did* work under those conditions remarkably well. The only thing that Prof. Forbes said was that they did not work in synchronism when coupled together with a number of incandescent lamps in series. The Brush Company were not at all afraid of that allegation. But he wished to point out that, in the first instance, Prof. Forbes had found a mare's nest, and that Mr. Mordey had taken a great deal of trouble to explain away that mare's nest without dropping on the actual bottom of it, although he had got very close to it. The peculiar phenomenon Prof. Forbes had observed was not an alternating current effect at all, and no question of alternating currents was needed to explain it, nor for that matter did they want any electricity in the question whatever. They had on the occasion to which Prof. Forbes had alluded two dynamos working in parallel driven by two similarly governed engines without load. What could happen under those circumstances but hunting? There was no such thing in the world as a governor that did not hunt, and there would not be until they got no friction; the centrifugal force must be enough to overcome the friction of the governor. This was what happened on that historic occasion at Messrs. Willans' works. One of the governors was hunting; the steam came on and carried the engine away a little faster, then the governor shut down and the speed dropped. Of course, the variations were small, but still quite sufficient for the purpose. That was repeated backwards and forwards. The same thing exactly would have happened if there had been two continuous current dynamos there, or if there had been no dynamos at all there. It would have been just the same if they had put one engine in front of the other and connected the two fly-wheels by a thin india-rubber band, when they would have found the top of the belt slack and the bottom tight, and the bottom slack and the top tight in regular pulsations. The mare's nest which Prof. Forbes had got hold of was nothing but a common mechanical effect, and had nothing whatever to do with the alternators, excepting as they rendered the effect visible.

Mr. SPARKES said the principal difficulty in the parallel running of alternators in parallel was to secure steam engines that would give them an equal turning moment. The synchronising current wholly depended upon the inertia of the moving parts, and if the change of speed varied very much during the revolution they found a very large current necessary. That was aggravated very often, as mentioned by Mr. Raworth, by governors. All governors hunted, and even when they had a governor with a very small amount of friction they still required a sensible amount of synchronising current. The difficulty was got over by having more than one cylinder. When they took a compound engine they certainly got better results than by having a single cylinder. In coupling large cylinders together he thought it advisable that there should be at least two high-pressure, if not three high-pressure cylinders, working on the same crank, so as to get a very equal turning moment. If they put a very heavy fly-wheel on the machine, of course they modified the amount of work done by the armature, but it was impossible in many cases to put on a sufficiently heavy fly-wheel to obviate the strain put on the armature.

*Mr. KAPP said it was an exceedingly happy simile to compare alternators worked in parallel with spur-wheels running in gear. There was only one restriction he would like to make on Mr. Mordey's method of representation, and that was where he contrasted flexible-teeth spur-wheels with those having stiff teeth, to the disadvantage of the former. As the paragraph read, they might be inclined to think that the idea of flexibility carried with it the idea of a weaker tangential force acting between the two wheels. If that were so, then undoubtedly the stiff-toothed wheel would be better. But there was no reason to suppose that the flexible tooth was not equally strong. It yielded a little, but the more it yielded the greater force it exerted, therefore it was perfectly compatible with the simile to imagine the two wheels having teeth of equal strength, only one wheel would yield through a certain distance before it attained that tangential force, whereas the other did not yield at all, and attained that tangential force at a blow, and for that reason he had always been an advocate of having machines with a certain amount of self-induction. The experiments in the Paper were, of course, undertaken and brought to their notice with a definite object, namely, to show that Prof. Forbes's objection was not one which would occur in practice; moreover, that it was not so detrimental to the working of the machine as he made out. But he (the speaker) thought Mr. Mordey had not done himself justice. Most of the experiments were made on motors running light. In one or two cases there was a load mentioned, but it was a small load for the size of the machine. Had Mr. Mordey really treated the machines as they would be treated in a power transmission, that is to say, had he put on a 50-kilowatt alternator a mechanical load of 50 kilowatts he would have found that it would have dropped out of step very much sooner than it did. He would like to say something about the V curves, which were exceedingly useful if one drew the whole of them. The curve, so far as it went, showed exactly the point at which the machine would drop out of step. There was this interesting fact about it, that if they had a transmission plant where the resistance in circuit was small and the self-induction was large, they would find that the left branch of the V became vertical, and then turned over, whereas the right branch of the V sloped out to a very great distance, in fact, so far that the machine could not take the great current which this branch would indicate as possible. The machine would not take it because it would get too hot. In a transmission plant it would be best to excite a little above the point which Mr. Mordey rightly considered theoretically the best point, that was, the bottom of the V. The curves were taken whilst the machine was running idle, and did not represent the true shape; the true shape would be more rounded at the bottom, and the arms would be more curved. If they had a transmission where the resistance was small, and for some reason or other had chosen motors with fairly large self-induction, it would be advisable to excite the motors higher than the generator in order that they might work on that branch of the curve which sloped indefinitely. With the bad conditions which Mr. Mordey artificially produced in order to test this point, namely, where they had a large resistance in circuit and little self-induction in the machines, the shape of the curve was different. The left branch began to slope very much more to the left; it was, in fact, a concave line to the horizontal, whereas the right-hand branch would very quickly turn over. The point

Digitized by Google

where the branch turned over showed the point where the machine dropped out of step. If they had large resistance in their line, that was to say, long lines, and could not afford to put in plenty of copper, they would then have, as Mr. Mordey rightly said, to work their motor at a lower excitation than the generator. But in general, when they used alternating currents for power transmission they were not under the necessity of wasting much power in their line, because they had the alternative to raise the voltage to such an amount that they could work with very small line loss, and that was no doubt the right way to work; but in that case the motor should be excited to at least the same electromotive force as the generator, preferably a little more, to give them a margin of power. It was all very nice to say that a 100-kilowatt motor was loaded to 100 kilowatts: it might be so if they averaged the load for the whole day, but under certain conditions, in fact, under most conditions, the load might often be considerably increased. His own machines were used in a power transmission in Switzerland. The machine was a 60-kilowatt alternator, and drove a factory, and when it was necessary to put on a heavy tool, or a whole row of tools, an enormous sudden strain was put on the machine, and instead of 60 kilowatts the machine did perhaps 100 kilowatts for the moment. They must have a margin of power, and they could get that by exciting the motor rather more strongly than the generator was excited—always supposing the line resistance was low. If it were high the machine could not deliver the power at all. As regards parallel running of alternators, he thought they had heard enough of the contention that certain alternators would run in parallel and others would not. It was not a question of the alternator, it was a question of the engine, and he could illustrate this best by his experience in Bristol. When Mr. Preece and himself designed the Bristol station they were perfectly well aware that an even turning moment was the only and necessary condition for working, and, in order to meet that condition, they specified engines with three cranks to work with alternators made by Messrs. Siemens, and when the engines were properly adjusted they could not read the synchronising current between the 80-kilowatt alternators and the 200-kilowatt alternators, and were quite sure the synchronising current did not reach five amperes. The following was interesting:—The expansion of each cylinder was adjusted separately. As a man had not three hands the expansions could not all be adjusted at the same moment. Therefore they got a slightly uneven turning moment, and the consequence was immediately visible on the ampere meters. As soon as they touched the expansion of one cylinder there was a slight jerk of the needle. As soon as they had adjusted all three the synchronising current became again negligibly small.

*Prof. SILVANUS THOMPSON said he hoped they might have had some further information and experience from those who had been manufacturing alternators and running them on a large scale. They certainly desired to have further data to discuss, particularly as to the question of the transmission of power from one alternator to another through a line of very considerable resistance, a line which of itself absorbed any considerable fraction of the power. There might well be cases where the generator and motor would not be similar, especially at the end of the line, where there was a measurable drop in voltage, and in that case it was probably advisable not to have the same degree of saturation of the magnets in the motors as would be the case if the machines were absolutely similar. With respect to Mr. Kapp's argument as to the flexible teeth being capable of driving as well as the rigid teeth, he (Prof. Thompson) might point out the reason why the flexible teeth, in the electrical case, were not so good for driving as the stiff teeth. It was that the very property of flexibility was not that there was a yielding, but that the yielding made the teeth less strong. There were some other ways of synchronising than those adopted in this country, and he would like some information about the American acoustic synchronisers. He would also ask whether anybody had had experience of a purely optical synchroniser? It was quite possible some optical synchroniser would be found more suitable and convenient than the electric forms. Lastly, he would ask whether anybody had had experience of the use of a common steam supply to the engines that were driving the machines which were running in parallel. It seemed to him that a good deal of the easy working of two engines working together might depend upon the question whether the steam supply was in common. It was desirable that they should have an expression of opinion, and a statement of actual experience gained in different stations with different types of governors and alternators.

The further discussion of the Paper was adjourned to the next meeting of the Institution on March 29th.

UNDERGROUND MAINS.

The following is an abstract of the discussion on the Papers on "Underground Mains," read before the Northern Society of Electrical Engineers by Mr. J. H. Rider and Mr. S. V. Clirehugh, and published in our last issue:—

Mr. WORDINGHAM said that, as regards the general questions of mains, the most important thing was durability. Take the case of vulcanised rubber cables. In Whitehaven they had a resistance of 1870 megohms—not per mile, but for the whole system as laid. Put on 1,000 consumers, each of one megohm, then the insulation resistance would only be 1,000 ohms; it was no use putting in thousands of megohms if the general resistance was only a few thousands of ohms. There could be very little doubt that copper was durable. Now, in Manchester they had partly bare copper in culverts and partly rubber. The resistance of bare copper was low; as to actual figures, he should not care to give any without having considered the matter first, but the figures which had got about were simply absurd; the resistance was said to be only a few ohms, instead of that it was certainly hundreds of ohms. As to rubber cables, he believed if the joints were properly vulcanised they could get perfect insulation. With regard to the question of vulcanising joints, the difficulty had been a little exaggerated. No doubt there was a large amount of difficulty in ascertaining the right duration of time for different mixtures and temperatures, but once the manufacturers gained this experience for them, and supplied them with vulcanising material that was ascertained to be good, there was very little difficulty in vulcanising joints. The great convenience of bare copper was the ease of getting on consumers. They simply had to sweat on a pair of thimbles and clamp them on to the bare mains.

Mr. A. B. MOUNTAIN thought that the difficulties of vulcanising were to be overcome by ordinary care, and considered the system of drawing vulcanised cables through cast-iron pipes in every way satisfactory for feeders or high-tension mains. Cables insulated with bitumen, paper, or fibre might be very good for low-tension mains, but were, he thought, unsuitable for high-tension work, unless laid with great care and at very considerable expense. With regard to the insulation resistance of the Manchester mains, there, of course, they had the continuous-current system with probably all the consumers connected on to one network. In the case of a town supplied by an alternating current the network would be divided, and the risks arising from leaks very considerably reduced, because the number of consumers connected on to any one section would be a small proportion of the total. The system of splitting up into small sections was a strong point with an alternating-current supply. In laying lead-covered cable underground, such as that proposed for Bolton, there were many points to be noticed. If the cables were laid in ground where there were traces of ashes they got serious trouble. Then the cables might be easily damaged by a blow from a pick or spade. If the cable was stranded into three, twisted in a spiral form, in the centre of the three circles of insulating material there would be a space not properly filled in, along which he should anticipate moisture creeping, and also when connecting consumers to the three-wire mains some difficulty might be anticipated in ascertaining to which pair of cables the consumer should be connected. He should like to know how the cables were distinguished.

Mr. BOURNE thought that Mr. Clirehugh in many ways under-estimated the capacity of paper as an insulator. At one time he had the problem set before him to make a paper cable for an alternating high-pressure current. Mr. Clirehugh said the insulation on the samples shown was very thin—it seemed to be about $\frac{1}{16}$ of an inch. The cables he (Mr. Bourne) made were successful, and the paper insulation had a thickness of about 17½ mils. There were seven thicknesses of the very finest paper. The cables worked at a pressure of 2,000 volts. They might get enormously high dielectric strength in paper; whether they could get the requisite strength combined with durability was a matter about which he had not had sufficient experience.

Mr. JAS. TAYLOR said that the only thing that struck him was that the difficulty of making rubber joints was over estimated. As regards paper and fibrous insulation, rubber had had ten years' experience and paper had not, and in another seven or eight years they would know more about it.

Mr. CONNOLLY said that it had often struck him that electric light work was more and more falling in line with the old telegraph work—that was to say, they were going back from the lower class of insulation to the higher class, and at the same time they were also going in a great deal more for the drawing-in system which was copied from the Post Office system for telegraph wires. The only thing they did not follow the practice of the telegraph world in was in the use of gutta percha. The reason for that was obvious. He could not conceive any permanent system of underground mains which did not consist of cables that were not only insulated but were also insulated with waterproof material, because sooner or later there was bound to be trouble with the insulation unless they could rely upon the insulating material being impervious to water. With lead-covered cables, with cables depending upon the lead for protection, they had the constant danger of a break in the lead or trouble at the extremities, and so long as they were dependent upon anything outside the insulating material for protection they could never feel safe. He heard on all hands of troubles with the underground copper mains, not so much in Manchester—things were new in Manchester—but in London, Paris, and elsewhere, even in places where there were supposed to be no troubles at all, and it had constantly been forced upon his mind that they could not rely in a permanent way on anything which did not consist of conductors insulated throughout. He did not know that indiarubber was the only material that could be used for the purpose, but it seemed to be the only one that had been used so far that answered its purpose in any way.

Mr. CLIREHUGH remarked that he withdrew his remarks about making indiarubber joints.

Mr. COWAN did not agree with Mr. Clirehugh's figures comparing the cost of laying armoured conductors direct in the ground with the same laid in cast iron pipes. He had tried Brook's oil insulation on a short line, and found it on the whole very satisfactory. The pressure was 2,000 volts.

Mr. BOURNE: Mr. Clirehugh seemed to think ten times a very severe test to subject a cable to. If Mr. Clirehugh would take any reasonably good cable—say for 100 volts—it would stand from 10,000 to 25,000 volts; that was his (Mr. Bourne's) experience. For instance, there was a cable he took out of the Crystal Palace—he did not know whose make it was—there was nothing extraordinary about it: but it took about 62,000 volts to break it down. It was only a short piece and was being used for a 100-volt circuit.

Mr. R. TAYLOR said he should like to state his experience as regarding vulcanised rubber. He had been engaged for the last 20 to 25 years in indiarubber cable making at W. T. Henley's and other places. A little had been said as to jointing. He did not think this should be treated lightly. His experience was that in vulcanised joints with care there was no fear of the joint going bad: but the greatest care should be exercised, and the workman should be thoroughly trained.

The discussion was then adjourned until April 9th.

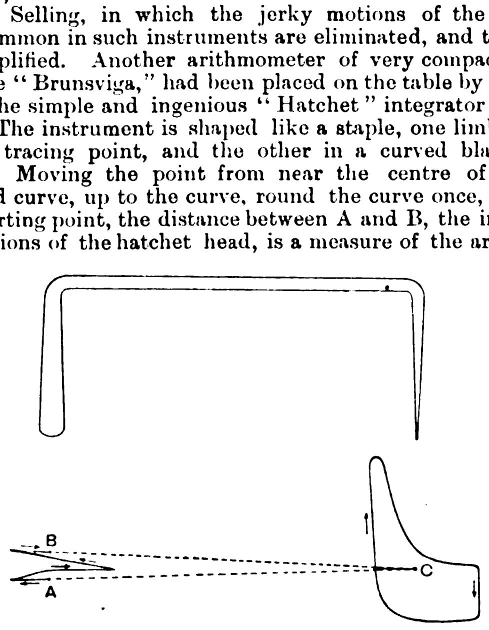
PHYSICAL SOCIETY.

At the meeting of the Physical Society held on March 9th, 1894, Professor A. W. Rücker, F.R.S., President, in the chair, Professor O. Henrici, F.R.S., made a communication on

"Mathematical Calculating Machines, especially a New Harmonic Analyser."

After mentioning the general principles on which such machines are based, the author showed a new arithmometer devised by Professor Selling, in which the jerky motions of the numeral wheels common in such instruments are eliminated, and the operations simplified. Another arithmometer of very compact design, named the "Brunsviga," had been placed on the table by Professor Boys. The simple and ingenious "Hatchet" integrator was then shown. The instrument is shaped like a staple, one limb terminating in a tracing point, and the other in a curved blade like a hatchet. Moving the point from near the centre of mass of any closed curve, up to the curve, round the curve once, and back to the starting point, the distance between A and B, the initial and final positions of the hatchet head, is a measure of the area of the



curve. The instrument has been found very useful for indicator diagrams. A Hine and Robertson's planimeter* lent by Professor Perry, an Amsler planimeter, combined with a pantograph for measuring small areas, an Amsler integrator to give areas and first moments, and a beautiful sphere and cylinder rolling-integrator of great accuracy by Coradi, of Zurich, were shown, as well as an ingenious integraph devised by Abdank Abakanowitcz.

Passing on to harmonic analysers, Professor Henrici explained the object of such instruments, viz., to determine the coefficients in Fourier's expansion for any periodic curve,

$$y = A_0 + A_1 \cos\theta + A_2 \cos 2\theta + \dots\dots$$
$$+ B_1 \sin\theta + B_2 \sin 2\theta + \dots\dots$$

and briefly described Lord Kelvin's instrument now in use at the meteorological office. This machine gives the first term and three pairs of coefficients A and B, but is large and expensive. The author had endeavoured to devise a simple and more portable instrument, and now described the various stages in the evolution of his new analyser. Using Clifford's method of wrapping the curve round a cylinder, he saw that by imparting a simple harmonic motion to a plane tangential to the cylinder, which plane carried an Amsler planimeter, whose tracing point followed the intersection of the plane with the curve as the cylinder rotated, any coefficient A_n or B_n could be determined. This arrangement had considerable friction, and only gave one coefficient at a time; it also necessitated readjustment of the period of the harmonic motion for each pair of terms. Another machine founded on integration by parts was then constructed, in which the relative periods of cylinder and registering wheels were adjusted by a disc and roller, the motion being transmitted to the wheels by bands driven from the disc spindle. This gave A_n and B_n at one operation. Mr. A. Sharp used this machine for some time, and then designed an inversion of it, in which the curve was laid out flat and the machine rolled over it. This arrangement greatly facilitated the multiplication of registering wheels, and thereby enabled several pairs of coefficients to be determined at once. The first machine of this kind showed several small errors, which were avoided in a second instrument, a specimen of which, made by Coradi, was exhibited and described. A rectangular frame, carried on three rollers (two being fixed to the ends of a long axis), traverses the paper in the direction of *y*, and the tracing point is fixed to a carriage which moves on the frame in a direction perpendicular to *y*, *i.e.*, in the direction of θ. A band is attached to this carriage and imparts a motion proportional to θ to two horizontal axes (one for the A coefficient and one for the $B^1 p$), placed above and parallel to the long roller axis above mentioned. Each of the two axes carries five pinions, having teeth in the ratios 1, 2, 3, 4, 5 respectively, which gear with crown wheels fixed to vertical spindles. The latter, therefore, rotate through angles proportional to θ, 2θ, 3θ, 4θ, and 5θ. To the lower ends of these spindles horizontal rings are attached, in which the bearings of a registering wheel are formed. Each wheel rests on a cylinder carried by the long axis, and rolls or slides thereon according as its axis is parallel or perpendicular to that of the cylinder. Moving the tracing point once round the curve gives five pairs of coefficients. By changing the driving band to other pulleys, so as to turn the pinions at different rates relative to the θ movement, the sixth, eighth, tenth, and seventh and ninth pairs can be determined.

The chief drawback of the instrument is that the registering wheels are not easy to read, whilst the backlash of the crown wheels and pinions introduces small errors. In the latest form of instrument toothed wheels are dispensed with, and glass spheres carried in frames on the vertical spindles roll on the horizontal cylinders. Each sphere actuates two registering wheels on fixed axes at right angles to each other, and these give respectively the sine and cosine coefficients. The number of vertical spindles is therefore halved, and the instrument greatly simplified. These details have been introduced by Coradi. A working drawing of another analyser, designed by Mr. Sharp, which gives the amplitude and epoch of the curve resulting from each pair of terms in Fourier's expansion, was exhibited.

The discussion on Professor Henrici's communication was postponed until next meeting.

Mr. H. Wilde, F.R.S., then exhibited and described his "*Magnetarium*." This consists of a hollow geographical globe wound all over the inner surface with insulated wire in planes parallel to the equator. Within this globe is a sphere wound with wire on its surface, and having its axis inclined at 23½deg. to that of the outer globe. By means of epicyclic gearing the spheres can be made to rotate at slightly different rates. When electric currents of suitable strength are passed through the two windings, the magnetic condition of the earth can be imitated, both as regards distribution at any epoch, and the secular variations. A better result was obtained by putting sheet iron over the land areas, and a still closer approximation by using thin iron over the water areas. A magnetic chart and tables giving the magnetic elements at various places for different epochs were shown. The author mentioned that recent observations by the United States Survey at Ascension Island, and by Professor Thorpe in Senegambia, had confirmed results obtained by the magnetarium.

The PRESIDENT said he had tried the apparatus, and found the Siberian oval closely imitated. The secular variations at Greenwich were also well shown. In South America the approximation was not so good.

In reply to a question by Mr. BLAKESLEY, Mr. WILDE said the present position of the pole of the inner sphere was 84deg. W., 67deg. N.

* Described in *The Electrician*, Vol. XXVI., p. 432.

ELECTRIC CONDUCTORS FOR FIERY MINES.*

BY JOSEPH LIBERT.

A Belgian royal decree of 1884 provided that safety lamps fed with pure vegetable oil should alone be used for lighting fiery mines, thus introducing an insurmountable obstacle to electric lighting in such collieries, which are the most numerous and generally the most important in Belgium. The progress made in electric lighting, however, and the great advantage of obtaining, in underground workings, better light than that afforded by ordinary safety lamps, brought about a modification, contained in the royal decree of February 12, 1893, which provided that owners of fiery mines might be authorised by the Minister of Agriculture, Industry and Public Works, to adopt electric lighting in their underground workings, subject to such conditions as may be judged necessary.

These conditions will chiefly bear upon means for obviating the danger of igniting firedamp by the production of sparks, and even voltaic arcs, caused by the interruption of a circuit, through any cause, either in the conductors or in the commutators and interrupters, while the incandescent filaments of the lamps would also be protected from any accidental contact with an inflammable mixture. Means should also be taken to prevent the heating of the conductors traversed normally or exceptionally by an excessive current, which might set fire to combustible substances, such as the timbering and coaldust, especially in dry collieries. Deficient insulation may occasion danger of the same kind, and also give rise to the production of sparks, if the tension be high, while it would expose the men to shocks, the consequences of which might be serious.

Most of these difficulties are now easily overcome. Heating of the conductors is avoided by giving them a sufficiently large sectional area; while the efficient ventilation of mine workings contributes to keep the conductors cool. The leads, which may be

* From a communication to the *Annales des Travaux Publics de Belgique*.

Digitized by Google

insulated as completely as desired, should be obtained from firms of repute; and this is a most important point, especially underground, where working is almost, if not entirely continuous, and the detection of defects is more difficult than in surface installations. The commutators and interrupters may be so arranged that any sparks are completely isolated from explosive atmospheres. The incandescent lamps, which can alone be used, will be protected by thick glass globes with absolutely tight joints.

The Belgian mine regulations do not oppose the use of electric motors in the underground workings of fiery mines, although such motors entail greater danger than electric lighting plant, on account of the higher tension of the currents employed, the production of sparks at the brushes of the dynamos, the heating of the armatures, and their accidental deterioration.

The author avows that in the present communication he has no intention of discussing the applications of electricity to mining, but will only deal with the subject of conductors, and especially those of recent invention for ensuring safety, and the chief object of which is to suppress danger from sparks, caused by an interruption of the circuit, owing to a movement of the measures, whether merely the fall of a stone or the falling-in of the roof. The experiments made by Profs. Wullner and Lehman, published in the report of the Prussian Firedamp Commission, do not appear to the author sufficiently complete or conclusive to warrant the belief that a spark, however small, is not dangerous in an inflammable mixture. Though it would be interesting, from a scientific standpoint, to establish the limits within which sparks may be regarded as free from danger, the question is very complex, and results favourable to security would scarcely be conclusive, if vitiated by a single adverse case owing to circumstances which it is often impossible to foresee, as was found in the official experiments with safety lamps and so-called safe explosives.

It would appear more logical to look for a solution of the problem as to the use of electricity in mines, in means for avoiding the production of sparks, or, at any rate, for keeping them out of contact with a dangerous medium. As regards electrical conductors, a maximum of protection may be obtained; and it may be asserted that conductors, properly made and laid by those accustomed to mine workings, will only break in very rare instances. On the other hand, it should be borne in mind that electric conductors exclusively laid in the main trolley-ways, in the neighbourhood of landings and in underground engine-rooms—in fact, wherever falls are least likely to occur, and where inspection is easy and the existence of explosive mixtures exceptional, except in the case of mines subject to sudden outbursts of firedamp, in which the mechanical effects may cause the breaking of the conductor, and so constitute a very present danger. It may, indeed, be concluded, on the whole, that electrical conductors, as now manufactured, afford a sufficient degree of safety in nearly all cases.

Concentric conductors, especially when well insulated and covered with a strong armour of galvanised steel wire, are very convenient for the transmission of electric current in wires, and may suffice, as regards safety, for most cases, being especially valuable when alternate currents are employed. As the forward and return conductors are enclosed in the same covering, the danger of shock due to contact with one of the conductors is avoided.

By arranging the conductors with plenty of slack against the sides of the workings, the movement of the measures will only have the effect of causing them to slide upon their fastenings; and an accidental crushing may have the effect of bringing the two conductors into contact, thus causing a short-circuiting, which would interrupt the line at its commencement by means of a fusible plug or interrupter. The degree of safety might be further increased by inserting the conductors in drawn iron pipes, so as to avoid crushing or accidental injury by tools or vehicles. It has also been proposed to lay them in the drains at the sides of the headings; but this practice is not advisable, as they would soon be deteriorated by the dampness, besides being out of sight, while the making of connections and the finding of defects would be more difficult.

Efforts have lately taken a new direction. Instead of endeavouring to ensure safety by the simple protection of the conductors, an arrangement is being devised by which the extra-current sparks shall be produced in a closed chamber, whatever accidents may overtake the conductors. It was in England that the first practical solution of the problem was obtained, a fact explained by the rapid increase in the employment of electricity in mines, thanks to the industrial liberty enjoyed. The author then goes on to describe the safety conductor invented by Messrs. Atkinson*, and determines by calculation the intensity of the current in the two branches of the shunt circuit, in the event of contact between the auxiliary and the main conductor, with the object of proving Messrs. Atkinson's assertion that the disengaging apparatus is by no means paralysed, but may still work. As the result of purely electrical calculations, the author concludes that the current will be capable of melting the fusible wire intercalated in the shunt-circuit, and of thus interrupting the main circuit, as in the case of a simple breakage of the external conductor only.

The author then says a few words as to the Charleton conductor, also containing a shunt-circuit, in which the induced current has the same direction as the main current. The subsidiary conductor, however, does not consist of a ribbon which may stretch if the conductor break, but of a single wire, so arranged that in all probability it would break before the main conductor, although not necessarily so. When this eventuality occurs, an interrupter cuts off the current of the main circuit—this interrupter being an electro-magnet, the coil of which is traversed in different directions by the main current and the induced current, so that they neutralise one another. If the auxiliary wire should break, owing to a movement of the measures causing a pull upon the conductor, the induced current would be interrupted by the breaking of the auxiliary wire, and the electro-magnet, influenced only by the main current, would interrupt it by attracting its armature. A slight spark would be produced inside the conductor through the breaking of the auxiliary circuit, the spark of the main current being produced at the electro-magnetic interrupter, placed out of danger, or suitably insulated, if contact be formed between the conductors by crushing. Equilibrium may also be upset, provided that supplementary resistance be introduced into the auxiliary circuit, in which case a phenomenon will occur similar to that with the Atkinson conductor.

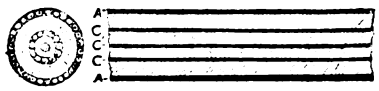


Fig. 1.

The author observes that, for doing any necessary repairs, it is necessary to remove from their attachments, and take up to the surface, both the cables or conductors above mentioned, because no soldering can be done in the underground workings. He then describes, as being free from this objection, a new safety cable or conductor invented by M. Noblet, engineer to the Cockerill Company, Seraing, when devising a system for permanently lighting by electricity some roads and landings in the collieries of that Company, the practical details having been worked out by M. Jaspar of Liège. The Noblet cable, while resembling the two above-mentioned in having a central auxiliary wire, differs totally from them in all other respects. Its essential characteristic is that the auxiliary conductor is traversed by a current of different direction from that of the main conductor, the diameter of the auxiliary wire being independent of the section of the main cable which surrounds it. The latter is suitably insulated from the auxiliary wire and from all external contact, being also protected by a strong armour of galvanised steel wire.

The system comprises two similar conductors, marked C C in Fig. 1, C′ being the auxiliary conductor, and A A the armature, while the insulator is represented by hatching. Each cable is, moreover, divided into sections, which also constitutes an innovation, the length of each section being determined by local circumstances. If the measures are solid, long sections may be adopted; but, in a district where there is reason to fear falls of the roof, their length would naturally be reduced. At each end of a section the cable is provided with a brass ring or coupling, both for the main and for the auxiliary conductor (as shown by Fig. 2, in which the same letters refer to the same parts as in Fig. 1), the rings of the

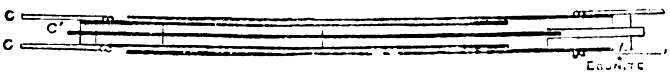

Fig. 2.

two adjoining sections fitting with easy friction. The small internal ring serves for coupling the auxiliary wire, while the outer rings connect the sections of the main conductor. These couplings are, however, so arranged that, if a sufficient effort be exerted to give them a sliding movement, a very slight displacement—about 5mm. or less than ¼in.—is sufficient to interrupt the circuit of the subsidiary conductor, while to entirely disconnect two sections of the cable the displacement must be considerable. Each ring is covered with india-rubber tubing, for insulating the cable at the joint, the tubing being firmly tied at both ends, so that there must be a little stretching before any displacement of the ring can occur, and this displacement cannot be effected without a certain amount of effort. Instead of rings, the two ends of adjoining sections may be connected by a wire wound round them like a spiral spring, the auxiliary wire being thinner and continuous at the joint, in which case, if strain be exerted on the cable, the fine auxiliary wire would break while the cable would stretch. The author, however, prefers the ring coupling, because, in case of a section becoming deteriorated, another may be substituted without the necessity of soldering or taking up the cable, an important point for ensuring the regular working of electrical appliances.

* This safety conductor was described in these columns, September 11, 1891, p. 527 (Vol. XXVII.)

Digitized by Google

The author then passes in review the various accidents which may occur to the cables, and the manner in which the Nolet system is calculated to prevent the formation of sparks.

There may be a pull upon the cable, through a movement of the measures, or any other cause, when the section upon which the strain is exerted will be immediately disconnected; and, as it is the auxiliary wire which will be disconnected first, the current in the circuit of the electro-commutators will be interrupted long before the rings conducting the main current become uncoupled.

So soon, however, as the auxiliary circuit, or that of the electro-magnets, is broken, the circuit of the two cables is immediately cut at its commencement. If, therefore, the couplings of two adjoining sections should happen to become completely uncoupled, no spark will be possible at the moment of separation, since the current will have already been interrupted.

As regards the small spark produced between the two ends of the interrupted auxiliary circuit, it is completely shut off from all communication with the atmosphere, since the two rings of the main conductor rub one against the other, and the surface of contact is considerable. If the rings be not injured by the accident they may again be coupled up, and, if necessary, the india-rubber renewed; and, to re-establish the current, the two armatures of the electro-commutators must be once more worked by hand.

The cables are also liable to still greater injury; they may be crushed under a fall of the roof, or cut by the shock of a vehicle or a blow from an axe, in which cases the main and auxiliary conductors come into contact, as in the Atkinson system. If such an accident occur to the positive cable only, a short circuit will be set up between the auxiliary wire and the positive cable; and a current nearly double the normal will pass through one of the electro-magnets, because, if the comparatively minute resistance of the conductors be ignored, the total resistance of the auxiliary circuit will be diminished by one-half, the other electro-magnet being out of the circuit, and the main current will immediately be interrupted. If, however, the crushing should occur to the negative cable, the same phenomenon will take place, but in a contrary direction. Normally, the current of the electro-commutators has an intensity of 0·06 ampere; and the shunt circuit has a resistance of about 2,000 ohms when the distribution tension is 120 volts.

Both cables may also break at the same time, although this is very unlikely to occur; and, even in the event of a very serious accident, it is probable that one of the cables will break first, if only a fraction of a second before the other. In the event, however, of both cables being crushed absolutely at the same time, both the electro-magnets will be traversed by a current double the normal, and neither of the commutators will be brought into action; but, thanks to the arrangement, the shunt-circuit will not be interrupted, while the fusible plug above mentioned offers further protection. If any considerable leakage should occur in either of the cables, through the accidental removing of its covering, for instance, the corresponding electro-magnet would let go its armature, and the distribution current would be interrupted before acquiring dangerous intensity.

The Nolet system lends itself admirably to the lighting of a headway in which the lamps are spaced out, instead of being grouped together, as in the neighbourhood of a landing or in an underground engine-room; and it is for this that it was devised. The author has repeated the experiments made at M. Jaspar's works, Liége, in the presence of a large number of engineers and mineowners, being impressed with the simplicity and practicability of the arrangement. All the various accidents were reproduced by which electric cables might be injured in mine workings, the effort of drawing asunder, crushing and contact with earth through denudation or other cause; and the results proved most satisfactory. One main fact in favour of safety is that the current cannot pass unless absolutely perfect. The cable experimented upon was calculated for a current of 8 amperes, at 120 volts capable of supplying 20 10-c. incandescent lamps, the electric energy consumed in the secondary circuit being 7·2 watts, or less than 1 per cent. of the total available energy. The ring couplings might serve for taking off the current for the lamps, so that the connections would thus be rendered as simple as possible.

M. Libert concludes his Paper by giving the principal conditions which an electrical system for mines ought to fulfil. The intensity of the current per square centimetre of sectional area should not exceed the figure obtained by the application of the formula deduced from Kennedy's experiments, from which it results that the heating caused by the normal current cannot exceed 10·4deg. centigrade above the surrounding temperature and 41·7deg. cent. when the intensity attains a value double that of the normal current. The diameter of the conductor satisfying this condition is deduced from the formula :—

$$d = 0{\cdot}374\, I^{\frac{2}{3}} \text{ ampere.}$$

in which d represents the diameter in millimetres, and I the intensity of the current in amperes.

All return of current by the earth should be strictly prevented. The insulation of the conductors should be sufficient for the tension of the current traversing them; and an earth indicator should be intercalated for giving warning if any leakage should occur. The main circuit and the various important branches should be protected by cut-outs or electro-magnetic interrupters, which should be put in action by a current exceeding from 50 to 100 per cent. the normal intensity. The commutators, interrupters, and cut-outs should be so constructed that no permanent voltaic arc can be produced between the metallic parts composing them. The appliances must be completely enclosed, their stands and covers being incombustible; and the lamp must be rendered harmless by being enclosed in an hermetically tight lantern provided with a thick glass globe.

The roads and places in which the electric appliances are placed should be well lined and provided with sufficient ventilation by a current of pure air; and in the event of an inflammable mixture being detected, the working of the electrical appliances is to be immediately suppressed, the protection of the cables forming the subject of special instructions in each individual case.

A CHEAP RECORDING VOLTMETER.*

The waste of energy in a recording voltmeter, due to the amount of force necessary to overcome friction, has caused the photographic method of obtaining records to be the one at which many inventors have grasped, and the present instrument is one of

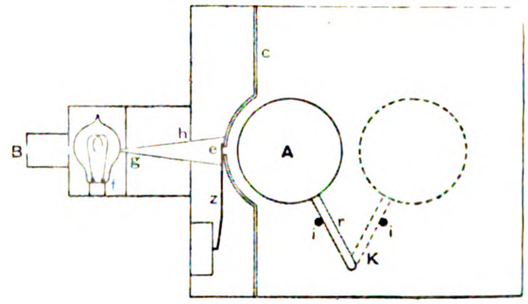

Fig. 1.

this class, and is of very simple construction, all systems of lenses or special darkened chambers being done away with; and, of course, the same principle is applicable to all registering instruments.

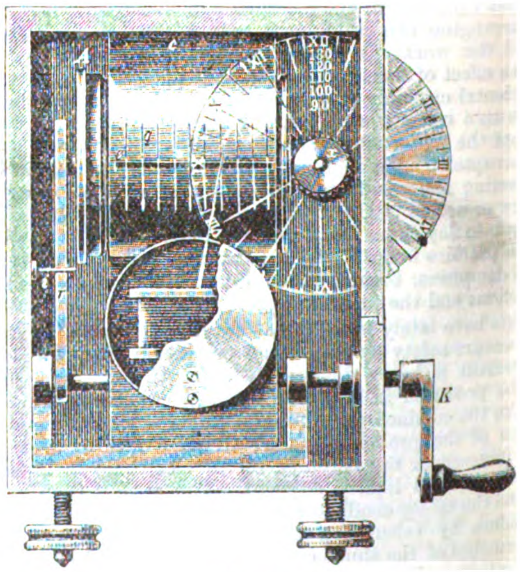

Fig. 2.

Fig. 1 is a diagrammatic representation of the working parts, in which A is the usual revolving drum, driven by clockwork, and

* From an article by Dr. A. Raps, *Zeitschrift für Instrumentenkunde*, January, 1894.

Digitized by Google

making one revolution in 24 hours, and carrying the sensitive paper. It is carried on a lever, *r*, and lies when in action against the stop *i*. Close in front of it, when in this position, is the metal plate *c*, having a fine horizontal slit *e* (which must be protected from

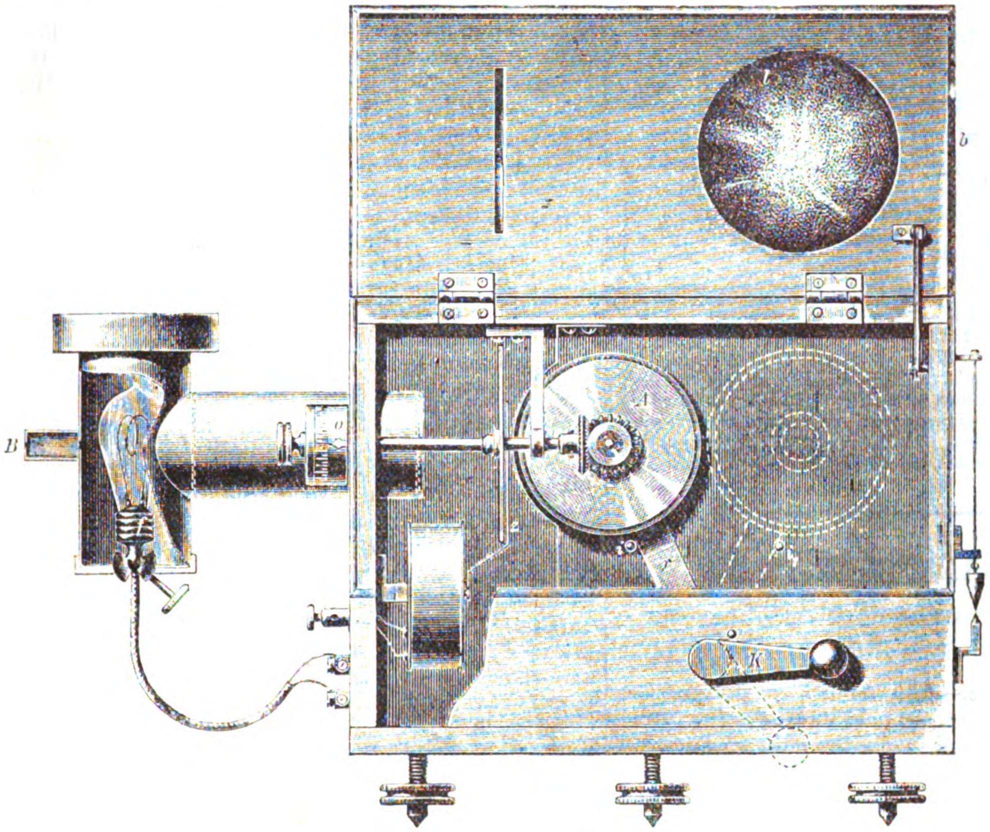

FIG. 3

dust), immediately in front of which the needle, *z*, of the indicating mechanism works; and in front of this again is the lamp. The result of this arrangement is, that when developed the paper shows the movement of the needle as a white line on a dark background, owing to the protection from light caused by the shadows of the needle. Fig. 2 shows the ingenious arrangement by which horizontal lines, corresponding to volts on the particular indicating mechanism used, are described on the paper by the shadows of the wires *g* stretched across the slit; while the shadow of figures

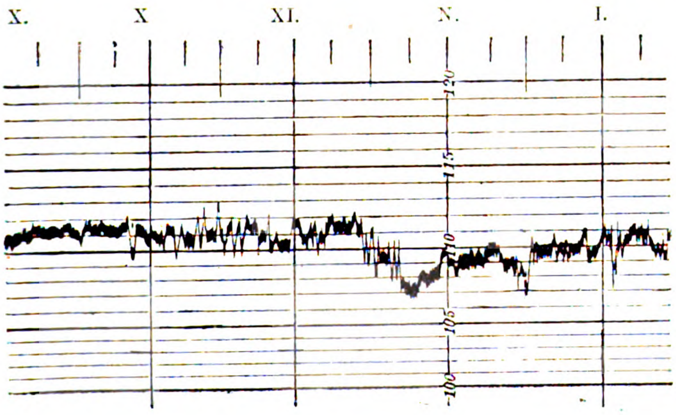

FIG. 4.

and radial lines on a rotating glass plate geared to the drum, mark the hours and quarters.

Suitable arrangements are made outside the case (*see* O, Fig. 3) for putting this plate in the correct position. The advantages of this method are great and obvious, since no special care is required in the setting of the paper, and no stretching can affect the results, and any indicating mechanism desired can be utilised. The method of introducing the sensitive paper in full light is described, and the same arrangements permit of its development and fixation in the same manner in open daylight; the exposure being always the same, no skill is required for these operations. It will be noticed that any violent depression in the volts, such as would not be taken account of by an ordinary registering voltmeter, owing to its very rapid movement, is plainly shown on this voltmeter by a white line on the paper, due to the momentary extinction of the lamp.

Fig. 4 shows a diagram of the pressure on the Berlin mains, and shows the figure and scale as marked by the instrument itself. The makers are the Allgemeine Electricitäts Gesellschaft.

LEGAL INTELLIGENCE.

Edison-Bell Phonograph Company v. The London Phonograph Company.

This was an action before Mr. Justice North, to restrain the infringement of a patent for improvements in the phonograph. The defendant trades at 62, Old Broad-street, under the name of the London Phonograph Company. The original claim in this country for a patent for Edison's phonograph was contained in his telephone patent, and was held bad as being an invention not covered by the provisional specification. The patent now sued upon is principally for a single diaphragm connected with both a recording and a reproducing point, so that the instrument can be used for recording and speaking by employing the diaphragm itself as a switch. The plaintiffs had established their patent in an action before Mr. Justice Wright, and now moved for an interim injunction.

The DEFENDANT admitted that to a small extent he had been in possession of instruments which to some extent infringed; but he said he had altered his instruments by removing the recording point, and that the instruments in his possession did not now practically infringe the plaintiff's rights.

Mr. Justice NORTH said that there having been an admitted infringement, and the plaintiffs having obtained a judgment in one action, they were entitled to an interim injunction in general terms, but directed against the particular instruments in possession of the defendant.

Winnipeg (Canada) Street Railway Company v. The Winnipeg Electric Street Railway Company, &c.

This was an appeal before the Judicial Committee of the Privy Council from a judgment of the Court of Queen's Bench of Manitoba, and the principal question raised was whether the City of Winnipeg could validly grant to the Winnipeg Electric Street Railway Company a right to lay down street railways and to run cars within the city in streets already worked by street railways of the appellant Company and in streets not yet worked by the appellants, but in which the latter were willing to work. The appellants contend that the city of Winnipeg was precluded from

Digitized by Google

granting competing rights to the respondent Company in either case, both by the terms of their statutory powers and also by an agreement made with them (the appellants). The respondents assert that no exclusive right was conferred on the appellants in the matter, and that any contract purporting to have that effect was not binding.

After hearing the arguments for the appellants, the LORD CHANCELLOR said their lordships would not require to hear counsel on the other side. They would deliver judgment on a future occasion.

Alley and Maclellan v. Latimer Clark, Muirhead and Co. (Limited).

This action, in which the record has been closed, was brought in the Courts of Session, Glasgow, at the instance of Messrs. Alley and Maclellan against Messrs. Latimer Clark, Muirhead and Co. (Limited), for payment of £726. 8s. 2d., the price of goods supplied by the pursuers to the defenders between August, 1892, and December, 1893. The pursuers state that the defenders have no domicile in Scotland, but they have been rendered subject to the jurisdiction of the Scotch Supreme Court by arrestments. The defenders explain that they are in liquidation, and that this action cannot proceed without the leave of the High Court of Justice (Chancery Division), England. They also state that the debt due by the Corporation of Glasgow to the defenders, which the pursuers had arrested, is claimed by Dr. A. Muirhead, London, as having been duly assigned by the defenders to him, conform to assignation in his favour, dated November 29, 1892, and bearing to have been duly intimated to the Corporation on January 12th last, more than a week before this arrestment was used.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, Saturday, *March* 3, 1894.

The Rating of Arc Lamps.—The annual meeting of the National Electric Light Association, held in Washington from February 27th to March 2nd, was one of the most successful in its history. Most of the Papers were largely of a trade nature, and, as is usual, the discussions by the station managers and others, though excessive in length were of little or no value. The subject of the rating of arc lamps was referred to a special commission consisting of Profs. Mendenhall, Anthony and Forbes and Messrs. Weston and Hammer, who reported that what is ordinarily known as a 2,000-c.p. arc should be defined as one requiring on the average 450 watts for its maintenance, the measurements being made at the lamp terminals with no sensible resistance in series with the arc. The report was adopted, and a question is thus settled that has been the cause of much friction between arc light companies and municipalities. A discussion on the most economical size of arc dynamos developed an almost unanimous opinion in favour of machines of 100 lights, and even more, for large stations.

The Scott Alternate-Current System.—The event of the Convention was the surprise sprung by the Westinghouse Company through the disclosure of a new alternating current system in a Paper read by its electrician, Mr. C. F. Scott. Mr. Scott began by pointing out the advantage possessed by the three-phased system in requiring much less copper and having much less self-induction than the two-phased system, while, on the other hand, the latter possessed a great advantage in regulation and required only two transformers where three were necessary in the three-phased system. He then introduced his new system, which is a combination of the two systems. By means of specially designed converters the currents generated by a two-phase generator are distributed as three-phased currents, and then either applied directly or transformed again to two-phased currents. Similarly two-phase apparatus may be used on a three-phase system. In the first instance, if one of the circuits be overloaded the action will only affect its own generator circuit and not interfere with the balance. The Paper was discussed by Profs. Rowland, George Forbes, and others. Prof. Forbes stated that the system was an extremely beautiful one, and on the face perfectly feasible and practicable. Prof. Rowland said that he considered that this work of Mr. Scott marked a new era in polyphase transmission; he was working along a similar line himself, and while he had succeeded in finding a way to transform the frequency as well as the phase, his method lacked the practical merits of the one under consideration. Profs. Forbes, Rowland and Scott all took occasion during the discussion to pay a tribute to the splendid work of Mr. Kennelly in simplifying alternating current calculations.

The Niagara Transmission.—The Niagara controversy cropped up several times in the discussion, and Prof. Forbes stated that no particular system had been adopted by the Cataract Construction Company, which was disputed by Mr. Stillwell, of the Westinghouse Company, who was sustained by Prof. Rowland. Mr. Stillwell claimed that the plans adopted at Niagara were substantially those developed by the technical staff of the Westinghouse Company, and were simply the Tesla polyphase system.

CORRESPONDENCE.

THE PARALLEL RUNNING OF COMPOUND-WOUND THOMSON-HOUSTON ALTERNATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your number of March 9th, Mr. Snell, in his series of articles, makes a statement in the part devoted to the "Compensating for the Drop of Pressure in Conductors," referring to the Thomson-Houston alternators, that alternators compounded as done by the Thomson-Houston Company will not work in parallel. I beg to correct this statement, and to give the result of experience and of different experiments made, which go to show how easy it is to run compound-wound alternators of this type in parallel.

At St. Brieuc, France, the Thomson-Houston Company installed in March, 1891 (see *The Electrician*, Vol. XXVI., April 24, 1891, p. 757) two 70-kilowatt alternators of 2,000 volts at no load, and over-compounded for 25 per cent. loss in the line. (The distance between station and centre of distribution is 13 kilometres.) These alternators are compounded precisely as described by Mr. Snell in his article, and have been running continuously in parallel in the most satisfactory manner. The dynamos are driven from the same line of shafting, operated by water wheels, care having, of course, been taken to adjust the pullies so that the dynamos run at exactly the same speeds under similar conditions of load, &c. A reactive coil was installed to facilitate throwing the dynamos in multiple. An instance which, however, goes to show the tendency of these machines to fall into step, even under most adverse circumstances, is that at one time, due to an accident, a part of the switchboard was torn down and the reactive coil short circuited, and when the switchboard was repaired the connections to one of the phase lamps were crossed, with the result that the operators at the station threw the machines in parallel every night when they were 180deg. out of phase, and this during a period of three months. They immediately came into phase with only a slight flicker in the lights. The effects were so slight that the operators did not call even the attention of the superintendent to the matter.

It is the regular practice at this station, before throwing machines in parallel, to place the rheostats in their field circuits in similar positions, so that the dynamos will have the same potentials when carrying the same load. On account of the heavy line loss in this particular case, when one alternator is running alone on the line at full load, its potential is about 2,300 volts, and the one to be thrown into circuit at that time has a potential of about 2,000 volts. The effect of the compoundage is such as to bring the two machines to the same potential when once in multiple. The rheostats in the exciting circuits of these alternators are such as to permit the variation of the potential of these machines from 1,800 to 2,700 volts on no load.

The following experiments were tried on these two alternators. They were put in multiple on a line load of but 15 amperes, which is about half-load for one machine alone. The load was fairly equally divided between them, and the line potential was 2,120 volts. Under these conditions half the resistance of each field rheostat was in circuit with its

Digitized by Google

particular dynamo. Progressively the exciting current of one dynamo was diminished to the minimum, and that of the other increased to the maximum, by means of these rheostats. The potential of the line current remained constantly 2,120 volts.

First one machine and then the other was excited to its maximum value, while the excitation of the other was reduced to its minimum. In each case it was the machine having the least excitation which carried the smallest current. The sum of the currents from the two dynamos was a maximum when the greatest difference of excitation existed. There was not the slightest tendency for the machines to get out of phase. By varying the compoundage of one or the other alternator, by means of the rheostat in shunt to compound winding, practically the same results were produced.

The fact that alternators of this type have been running in multiple at St. Brieuc for the last three years, overcompounded 25 per cent. and driven from the same countershaft, that they run and stay perfectly in parallel when one is excited fully 50 per cent. more than the other, and can be thrown in multiple without danger, even when they are 180deg. out of phase, surely shows that compound alternators built on the principle described by Mr. Snell can be satisfactorily operated in parallel.—Yours, &c., E. M. Mix.

11, Rue Vezelay, Paris, March 15, 1894.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I beg to thank Mr. E. M. Mix for kindly calling my attention to a mis-statement on my part in "Electric Motive Power." I am much interested by his account of the parallel working at St. Brieuc, which leaves no doubt of the suitability of Thomson-Houston alternators for running parallel.—Yours, &c., Albion T. Snell.

EDDY CURRENTS IN AN INDUCTOR ALTERNATOR.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The description of a new alternator by the Compagnie de l'Industrie Électrique in your last issue does not give any particulars of the eddy current losses which must occur in the inner ring of the fixed magnet.

This is apparently a solid casting of steel, and is subject to the same varying magnetic flux as are the armature coils. A statement of the power absorbed by this machine on open circuit would be interesting.—Yours, &c., John H. Rider.

Town Hall, Bolton, March 12, 1894.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: As might have been supposed, the internal ring of the magnet in this alternator is not a solid casting of steel. It is built up of sheet iron. This was not shown in the drawing, which was intended as a diagrammatic sketch, and not as an exact representation of the actual machine.

On open circuit, the machine producing the full voltage at the normal speed, and apart from excitation, 10,200 watts were absorbed. At normal speed, without excitation, the power absorbed amounted to 4,200 watts, thus leaving 6,000 watts for the loss by hysteresis and Foucault's currents. This refers to a 275 kilowatts alternator, and shows that the metal has been carefully laminated.—Yours, &c.,

Pro Cie. de l'Industrie Electrique,

Geneva, March 16, 1894. L. Goichot.

ARC LAMPS ON ALTERNATE CURRENT CIRCUITS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Referring to the description of the Scarborough electric lighting in your last week's issue, it appears to me that the sub-stations with single transformers may under certain conditions be most unsatisfactory. Suppose that 20 per cent. of the load of one of these transformers consists of arc lamps with choking coils for regulation, the effect of switching on these lamps will be to so reduce the volts at the transformer as to spoil the incandescent lighting. The inductive resistance in the circuit reduces the volts in a very marked way, and I could point to cases where (the transformer being of ample size for the load) the presence of a single arc lamp lowers the voltage so much as to make the incandescent circuits quite dim and useless. I have never seen this question brought forward, but it is of considerable importance, and perhaps some of your readers have had the same experience and found how to get over the difficulty.

Of course, if ordinary resistances are used for the arc lamps instead of choking coils, and lamps are selected with small induction, there would be no trouble, but one uses choking coils because of the small amount of energy wasted in them. The saving, however, is effected by reducing the volts, and as most electricity meters are current meters only, the consumer does not reap much advantage. It is the custom with some supply companies to put in a separate transformer for arc lamps, but this would be hardly possible in the case of distributing from sub-transformer stations.—Yours, &c.,

J. O. Girdlestone.

16, Davies-street, Berkeley-square,
London, March 19, 1894.

IRON TESTING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: If Messrs. Parsons and Co. would explain how they obtain equal induction in the two samples they are comparing for hysteresis loss it would be easier to estimate whether their method has any advantage over others. As we understand their explanation, a core of laminated brass would appear by the test to be excellent material for a transformer. We are also not clear how the induction can be varied appreciably by increasing the weight or cross section of the core.

We may say that some time ago we carefully considered testing for hysteresis loss by means of a comparison of temperature rise; but abandoned the idea in favour of a modification of Prof. Ewing's method for obtaining the complete hysteresis curve.—Yours, &c.,

The Manchester Edison Swan Company (Limited),
March 20, 1894. Per E. W. C.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "The Electrician" Electrical Trades' Directory and Handbook is now ready. This valuable book contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

"Electrical Engineering Formulæ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.) A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). prospectus on application to the Publisher.

"Electromagnetic Theory," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"Drum Armatures and Commutators."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

Tenders Accepted.—Messrs. Verity and Sons have obtained the contract for the electric lighting of the Blackpool Tower, and have arranged with Messrs. Siemens Bros. and Co. for the supply of the necessary dynamos for the installation, which is on a large scale.

——— The tender of the Fowler-Waring Cables Company (Limited) has been accepted by the Brighton Corporation for the supply and laying of armoured and lead-covered electric cables. Tenders were also received from W. T. Henley's Telegraph Works Company (Limited), the British Insulated Wire Company (Limited), the Callender Company, the India Rubber Company, Messrs. Siemens Bros. and Co. (Limited), and Messrs. W. T. Glover and Co.

Digitized by Google

APPOINTMENT VACANT.—The Guardians of the Dewsbury Union require a "competent man to act as consulting engineer," and to superintend the erection of the electric lighting installation plant at the workhouse. Candidates must have had experience in similar work, but must not be contractors, nor in any way interested in contract work. Applications must be sent in by the 28th inst.

LIQUIDATIONS.—It is notified by Mr. F. S. Lucey, the official liquidator to the International Cable Company (Limited), that, by an order dated February 15 last, the chief clerk directed a dividend of 20s. in the £ to be paid to the creditors of the Company.

——— Meetings were held on Friday last before Mr. Warley, Assistant Official Receiver, of the creditors and shareholders of Newington, Priddle and Co. (Limited). An abstract of the Official Receiver's statement appeared in our issue of the 9th inst. At the meetings the Chairman reported that shortly after the winding-up order was made the whole of the property and the goodwill were sold for £330. With the exception of the collection of the book debts, there remained very little to be done under the liquidation proceedings. Resolutions were passed for the Official Receiver to act as liquidator and wind up the Company, assisted by a committee of inspection to be subsequently elected.

——— Mr. J. H. H. Duncan, of 39, Coleman-street, E.C., has been appointed liquidator of Elmore's French Patent Copper Depositing Company (Limited).

——— A meeting of the Thorneburry Miners' Safety Lamp Company (Limited) is to be held at 18, St. Swithin's-lane, E.C., on April 18th, at 11 a.m., to receive an account of the winding up.

INCANDESCENT LAMPS.—Messrs. Laing, Wharton and Down announce that they are prepared to supply a new incandescent lamp, called the "L. W. D.," at low prices.

——— Messrs. Barclay and Son send us particulars and price list of incandescent lamps manufactured by Messrs. Pulsford, Triquet and Co., for which they have been appointed sole agents.

MESSRS. JOSEPH BOURNE AND SON.—This old-established firm of makers of vitreous Denby stoneware insulators, battery jars, cable tubes, &c., send us a copy of their newly-prepared illustrated list of insulators and other manufactures for which the firm are well known.

ELECTRO-HARMONIC SOCIETY.—The last concert of the season of this society will be given on Friday evening, the 30th inst., at the St. James' Hall Restaurant, Regent-street, London, W., at eight o'clock. An excellent programme is provided, under the musical direction of Mr. T. E. Gatehouse and Mr. A. E. Izard.

EMPLOYERS' LIABILITY.—In the Westminster (London) County Court, on Monday last, an action was brought against Messrs. Verity and Sons by a workman lately in their employ, named Taylor, to recover damages for personal injuries alleged to have been sustained through the negligence of the defendants' foreman. For the defence, Edward Bowen, the defendants' foreman, stated that they were fitting electric call bells to the lift at Whitehall-court, and that it was through the plaintiff's own fault that the accident happened. After hearing the evidence, the jury found for the plaintiff for £60 and costs.

MESSRS. WOODHOUSE AND RAWSON UNITED (LIMITED).—Some misapprehension exists as to the sale of the premises of the Cadby Hall Works at Hammersmith, formerly occupied by this firm in the manufacture of their electrical and general specialities. We are asked to state that the whole of the work previously carried out at Hammersmith has now been transferred to the extensive Cornbrook Works at Manchester, where all the plant and apparatus of Messrs. Woodhouse and Rawson's make is now manufactured.

MESSRS. BULLERS (LIMITED).—It is stated that this Company have in contemplation the removal of their works from Dudley to Tipton. A portion of the Company's workshops at Dudley were destroyed in a gale about two months ago.

MESSRS. HODGES AND TODD.—Increase of business has necessitated the taking of additional works premises at Hampstead-road, N.W., where the additional plant will be driven by electricity supplied from the St. Pancras mains. The firm's offices remain at Turnmill-street, E.C.

MESSRS. BENNETT AND DRUCE.—This firm have received instructions from Messrs. Horrockses, Crewdson and Co., cotton spinners, of Preston, Lancs., to put down three 500-light dynamos in their cotton mill now in course of erection. An interchangeable system of wiring has been devised by Mr. Druce, rendering complete failure of the light an impossibility. It is estimated that about 900 lamps will be required.

MESSRS. BAXENDALE AND CO.—The electrical department of this firm are supplying and equipping complete search-light plants for the night navigation of the Manchester Canal, including the necessary staff for working the same. From a testimonial received by the firm from the master of the s.s. "Grampus," it appears that the search lights have proved of great service in the navigation of the Canal at night, the passage having been made by this vessel, on the night of Friday, the 2nd inst., in a little over five hours.

MESSRS. MAUNSELL, MERCIER AND CO.—This firm have secured the contract for wiring, fittings, and complete plant for the installation of about 600 16-c.p. incandescents at the Deansgate Hotel, Manchester, the generating plant including two 30-b.h.p. gas-engines and two dynamos.

MESSRS. O. BEREND AND CO.—This well-known firm send us particulars and prices of the Hambruch patent positive feed pneumatic and automatic oil lubricating system. The particulars issued give an illustration of an installation of this system applied to shafting, for which economy in oil, wages, attendance, &c., are claimed. The system consists of an air compresser for forcing air through a network of tubing on to the surface of the lubricating oil contained in specially-constructed patent lubricators, causing the oil to be fed on to the bearings in proportion to the pressure, and shows at a glance the rate of feed and contents of all the lubricators. Instructions for using are included in the list. Messrs. Berend and Co. also issue List F, devoted to description and prices of Gülcher's Patent Thermopiles, manufactured by Julius Pintsch, of Berlin, for whom Messrs. Berend and Co. are the agents in this country.

AYR.—The Town Council recently decided to consult Sir William Arrol as to the advisability of appointing an electrical engineer to arrange for a survey to be made of the borough for electric lighting purposes. On Sir William's advice it has been decided to ascertain first of all the arc lamps likely to be required, and also the probable amount of support householders in the district are likely to accord the electric lighting scheme. The surveyor to the Council has been authorised to visit towns of a similar size to Ayr for the purpose of obtaining information on the electric lighting subject, and to lay the same before the Electric Light Committee.

BATH.—An application made to the Corporation by the City of Bath Electric Lighting Company for power to extend their mains beyond the present area has been declined by the Lighting Sub-Committee.

BOMBAY.—The Municipal Corporation recently held a meeting, at which, in order to recover rates and taxes due from the late Eastern Electric Light and Power Company, it was decided that an application should be made to the High Court for an order authorising the sale of the Company's deposit of 5,000 rupees lodged in connection with the agreement between the Company and the Municipal Corporation in 1883.

BRECHIN.—Mr. Jamieson, a member of the Town Council, has given notice that, at the next meeting of that body, he will move that application be made to the Board of Trade for a Provisional Electric Lighting Order.

CASTLEFORD.—Having received Mr. R. Hammond's report on electric lighting, the Chairman of the Local Board said that he had gone carefully through the documents, but had come to the conclusion they were not in accordance with the requirements of the town. Mr. Hammond has been requested to forward plans and all necessary particulars.

CHURCH LIGHTING.—The restoration of Bristol Cathedral, which has been in progress for some time, is approaching completion, and the electric light fittings are shortly to be added.

CARDIFF.—Mr. W. H. Massey, the electrical engineer to the Cardiff Corporation, stated at the last meeting that nearly 14,500 yards of pipes had been laid, leaving about 2,500 yards to be completed, and that the electric current would be ready for public lighting in about three months. There is some talk of Mr. Massey being proceeded against for libel by a Company associated with certain patents for utilising dust in the generation of steam. It appears that Mr. Massey has, in connection with the glowing accounts recently appearing in the Press as to what is likely to be done in the near future by the use of dust destructors, fallen foul of the Company referred to, who threaten to take proceedings. At a meeting of the Electric Light Committee of the Cardiff Corporation on Tuesday last Mr. Massey stated that he had intended to ask permission to make an explanatory statement as to the answer he gave at the last meeting of the committee, but as legal proceedings were threatened he would offer no explanation now. It would be in the recollection of the committee that he declined to express any opinion on the particular system of refuse destructor, to which attention had been called, and the remarks he made had reference only to a press show, about which he had read reports.

COMMISSIONERS OF SEWERS (LONDON).—At their meeting on the 20th, the Commissioners were invited to sign a petition against the Central London Railway Extension of Time Bill, but on an undertaking by the Central London Company to reduce the time

Digitized by Google

for the completion of their work to the year 1899, it was agreed that no opposition be made to the Bill. Colonel Haywood, the engineer to the Commission, has for some time past been suffering from ill-health, and it has now been decided to retain his services as Consulting-Engineer at the present salary. The question of appointing another engineer remains in abeyance. It has been decided by the Commissioners to appoint a valuer, whose services will be first required in the preparation of a report as to the City of London Electric Lighting Company's works, and their liability to assessment. Mr. Walter Barnett, of Winchester House, E.C., was appointed. The Committee, in recommending Mr. Barnett's appointment, express great confidence in his skill and judgment.

Country House Lighting.—Kylemore Castle, the seat of Mr. Mitchell Henry, in the West of Ireland, has been lighted throughout by electricity from designs made and carried out by Messrs. J. C. Howell (Limited), of Queen Victoria-street, E.C., under the superintendence of their engineer, Mr. Furniss. Water from a number of small mountain streams is collected in a natural lake, situated at about 400ft. above the level of the house, which is situated in a very isolated position. The presence of this water power has enabled Messrs. Howell to utilise a "Girard" high-pressure turbine coupled to a Crompton dynamo, from which the supply of current has given every satisfaction. Interior lighting is effected by 270 incandescents, and the terrace is lighted by two 500-c.p. arcs, mounted on wrought-iron standards. The current is also used to heat a hot closet for kitchen use. The installation includes the outlying buildings, stables, &c., and is ultimately to be extended to the memorial church, post office, dairy, and farm buildings. Special difficulties were met with in carrying out the work, all of which were satisfactorily overcome.

Dartford.—Mr. W. Greig, a member of the Local Board, is preparing an electric lighting scheme for Dartford, and the fact that the Local Board have refused to renew the contract with the local gas company for more than one year indicates a disposition on the part of the majority on the Board to give Mr. Greig's scheme every opportunity.

Derry.—The town of Derry was on Saturday last *en fête*, the citizens coming out to witness the turning on of the electric light. From the descriptions of the ceremony attending the public inauguration which appear in the local press, the ratepayers appear to be immensely pleased with the installation. The streets of the town were brilliantly lighted from seven o'clock to 10:30. The contract is not yet quite completed, and the city will not be lighted by electricity permanently for a week or two, as there are still some lamps to be put up in two or three of the principal thoroughfares.

Dundee.—The electric light has now been established twelve months at Dundee, and Mr. D. Urquhart has completed his inspection of the installation. Everything is certified as satisfactory.

Grange.—The Chairman of the Local Board had a notice on the paper for the last meeting, recommending the application for a Provisional Order by the Local Board, but the cost of the application, which was estimated at £250, induced him to withdraw his proposal. At the same time he thought that no time should be lost before going into the question of the cost of the lighting of the district by electricity, which he considered would be much cheaper and better than their present costly system.

Guildford.—A long discussion took place at the last meeting of the Town Council upon the electric lighting question. The General Purposes Committee have reported that they have considered the question, and, after an interview with the promoters of the electric lighting Provisional Order, they recommend the Council to oppose the granting of such an Order to the present applicants, and to resolve that, at the close of the present year, they will themselves take the necessary steps to apply for an Order. A report was also presented from Mr. A. F. Phillips on the water supply and pumping machinery, which is identified with the general scheme of electric lighting. Mr. Phillips's report contains some elaborate suggestions with regard to the electric lighting scheme, and, after a full discussion, it was decided to adjourn the meeting to allow the General Purposes Committee to bring up a further report.

Killarney.—The Town Commissioners have discussed a resolution instructing the clerk to ask Mr. Santry to continue the lighting of the town by electricity until all questions concerning the contract are decided, and that, as some doubt seems to have arisen as to the contract for public lighting, tenders be again advertised for on the same terms as in August last. This proposal was agreed to, and came again before the Commissioners at their last meeting.

Lambeth.—The Vestry of this parish have given their consent to an application of the Crystal Palace District Electric Supply Company for a Provisional Order under the Electric Lighting Acts. The Order, however, only refers to a small portion of the Lambeth parish situate at Gipsy Hill.

Liverpool.—The Palace, a popular pleasure resort at New Brighton, has recently undergone considerable alterations, and the whole of the premises, both inside and out, are now lighted by electricity. The plant includes a 32-h.p. Campbell gas engine and a 300-light Phœnix dynamo, the installation being carried out by Messrs. A. Hall and Co., of South John-street, Liverpool.

Llandrindod Wells.—The chairman of the Local Board has reported that, from inquiries he has made, and after an inspection of the electric lighting installations at Morecambe and Blackpool, he is convinced that an installation worked by gas power will be found most suitable for their district.

Maidstone.—The Local Board have disposed of the question of electric lighting, which has been under discussion for some considerable time. The Committee appointed to discuss the matter have met several times, but have come to no final decision in the matter. At the last meeting of the Board it was proposed by Mr. Barker that the Board should themselves carry out the Provisional Order for lighting the borough by electricity, the time for the Board taking the matter in hand themselves having nearly elapsed; but, after a lengthy discussion, it was decided, on the motion of Alderman Ellis, to transfer the Provisional Order to a company.

Plymouth.—Tradesmen and other large consumers of light are complaining that the "metropolis of the west" is lagging behind on the question of electric lighting. Whereas quite a number of western towns (both small and large) either have the benefits of the electric light, or are contemplating their early introduction, Plymouth still keeps behind in this important matter. The only move at present made is that the gas company has given notice to apply for Parliamentary powers.

Ruthin.—Col. Cornwallis West, a large landowner and resident, has written to the Town Council asking for information regarding the electric lighting scheme, which was some time ago under consideration, and expressing his intention of adopting the light, should it be introduced.

Stirling.—From reports to hand of the discussion at the Town Council's meeting on the resolution that the local authority should at once apply to the Board of Trade for a Provisional Order for electric lighting purposes, it is clear that everything was done to induce the members of the Council to support their original decision that the Council should themselves undertake the electric lighting of the district. Notwithstanding this, by a majority of two in a council of twenty, it was decided that the Caledonian Electric Supply Company should be allowed to proceed with their application. The Council instructed the Town Clerk, however, to inform the Company that the Council wished to have an opportunity of making terms with them, and a special committee was appointed to take the matter in hand.

Walsall.—The Board of Trade have provisionally approved of the Town Council's electric lighting scheme, and the Town Clerk has applied to the Local Government Board for borrowing powers to carry the scheme into effect.

West Ham.—A motion was recently carried at the Town Council to adjourn the consideration of the electric lighting question for six months. At the last meeting it was agreed to refer the matter to a committee.

Weston-super-Mare.—A memorial has been presented to the Town Commissioners, calling attention to the present inefficient system of public lighting, and asking the Commissioners to take into consideration the practicability of installing the electric light throughout the district.

Works and Office Lighting.—At the meeting of Spratts Patent (Limited), the Chairman informed the shareholders that at the extensive works at Bermondsey, where the Company are engaged in the making of their well-known specialities, the electric light has been installed throughout.

Worcester.—Mr. Preece anticipates that the public supply of electric current will be ready by October next. This installation will constitute by far the largest water-driven electric lighting works in the country. For many years the Worcester Corporation has discussed the advisability of purchasing the gas undertaking. When the subject of electric lighting came up for discussion recently many members of the Corporation considered the time had come when, failing the purchase of the gas works, they might enter the lists as a healthy competitor to the gas company. The fact that Worcester is well served by the Severn, and that therefore water power would be at the Corporation's command, lent increased force to the arguments in favour of the Corporation's undertaking the supply of electric current throughout the district. Some initial difficulties and objections from the Severn Navigation Commissioners had to be overcome, but these were at no time a serious matter, and finally everything was settled satisfactorily by

Digitized by Google

an offer from Mr. Willis Bund to sell the old water mills on the Teme at Powick. Mr. W. H. Preece was then called in, and with Mr. Purchas, the late city surveyor, and Mr. Thomas Caink, who has succeeded Mr. Purchas in that office, proceeded to prepare a scheme involving an expenditure of over £42,000, of which £23,500 represents plant, machinery and apparatus, and £15,000 the cost of the erection of the central station building. During the progress of the work everything has run smoothly but for for one mishap—the temporary dam gave way, and for some days the whole of the work was submerged. On the water having been pumped out the heavy masonry work was proved to have sustained no damage. The works are not likely to suffer through any scarcity of water power, as there is much more than sufficient for the purpose, although it is not continuous. On this account powerful steam engines have been provided for emergencies. The Brush Company have supplied the electrical plant. The water power is to be developed by four inward-flow Victor turbines, two of 54in., one of 38in., and one of 30in., providing nearly 350 h.p., and capable of developing up to 800. The work is being superintended by Mr. Leonard Wigan, as clerk to the works, who has under his care what will doubtless prove one of the most important installations in the country.

YORK.—The Streets and Buildings Committee of the Corporation have decided to defer coming to any resolution on the subject of electric lighting until they are furnished with further information on the subject, and have been able to visit Oxford to inspect the installation works there put down by the Electric Construction Company.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

February 24, 1894.

3,986. W. P. THOMPSON. Liverpool. Improvements in electric motors. (The Ries Electric Specialty Company, United States.)*

3,994. A. J. BOULT. London. An improved electrolytic process for covering or coating threads, fabrics, feathers, or other articles or materials with metal. (A. Soret, France.)

4,005. K. BEHRENS. London. Dynamometer for mechanical musical instruments.

4,010. W. B. ESSON. London. Improvements in winding the armatures of dynamo machines of the drum type.

4,021. A. C. BROWN. London. Improvements in telephone transmitters and arrangements for same.

February 26, 1894.

4,055. P. E. E. RAVEROT and G. A. HESS. Paris. Improved telephone exchange system. (Date applied for under Patents, &c., Act, 1883, sec. 103, August 8, 1893, being date of application in France.)

4,083. K. SCHLEYDER. London. Improvements in electric arc lamps.*

4,091. F. JEHL and M. VON HARDTMUTH. London. Appliances for the carbons of electric arc lamps for increasing the duration thereof.*

4,096. J. L. COPPING. London. Improvements in cable traction operated by electricity as a motive power.

4,102. H. A. C. SAUNDERS and A. C. BROWN. Improvements in street fire alarms and telephonic combinations for same.

February 27, 1894.

4,113. H. T. BARNETT. London. Improvements in electric batteries.

4,142. A. R. UPWARD. London. Improvements in construction of electrical letters and signs.

4,144. E. O. CLARK. London. Improvements in electrodes for arc lamps.*

4,168. A. W. HUSSEY. London. Improved construction of electric battery.

4,170. W. P. THOMPSON. Liverpool. Improvements in alternating-current electric motors. (C. S. Bradley, United States.)

4,171. W. P. THOMPSON. Liverpool. Improvements in alternating-current electric motors. (C. S. Bradley, United States.)

4,177. W. P. THOMPSON. Liverpool. A new or improved reel device for fire hose, electric cables, suspending cords, and the like. (P. Schneider, Germany.)

4,182. L. HIGGINBOTTOM, T. MANNOCK, and E. HOPKINSON. Manchester. Improvements in overhead electric travelling cranes.

4,190. E. L. BERRY and F. HARRISON. London. Improvements in apparatus for use with electrically-illuminated signs or advertisements, or in other cases where frequent changes of electric circuits are to be made.

4,197. F. W. BUSCH. London. Improvements in or connected with bases or covers for electric switches and fuses.*

February 28, 1894.

4,214. W. L. SPENCE. Manchester. Improvements in or in connection with electricity and other meters.

4,226. R. H. JAHR and C. F. SCHOELLER. London. Improvements in electric arc lamps.

4,235. J. W. EWART. London. A new electric fitting for piano.

4,244. A. DICKINSON. Birmingham. Improvements in and relating to the overhead system of electric tramways.*

4,254. J. C. B. ANDREWS. London. Improvements in electric arc lamps.

March 1, 1894.

4,325. A. H. HARRIS. Birmingham. Improvements in the electro-deposition of aluminium.

4,326. T. BAMBER and O. BAMBER. Accrington. Lamp, answering the purpose for cap and loop lamp (for incandescent lamps).

4,333. W. H. JOHNSON. Bournemouth. Improvements in and relating to apparatus for supporting and suspending electric light and other like fittings.*

4,366. A. J. BOULT. London. Improvements in dynamo-electric machines. (Compagnie de l'Industrie Electrique, Switzerland.)

March 2, 1894.

4,402. H. G. REA. Richmond. An electricity meter.

4,429. A. METZGER. London. Improvements in and in the manufacture of electrical switches.*

March 3, 1894.

4,472. T. PARKER. Wolverhampton. Improvement in electrolytic processes in the manufacture of chlorine alkali and derived products.

4,477. J. HESKETH and T. HESKETH. Blackpool. An improved automatic regulator for electric generators.

4,484. G. MICHAELSON. Berlin. Electro-magnetic switching.

4,485. G. MICHAELSON. Berlin. Correction of an electric bell.

4,522. A. J. BOULT. London. Improvements in electrically-operated clocks. (H. Campiche, Switzerland.)*

4,539. W. DIESELHORST and SIEMENS BROTHERS AND CO. (LIMITED). London. A joint for wires and electrical conductors.*

4,540. SIEMENS BROTHERS AND CO. (LIMITED). London. Improvements in contact bars for the overhead conductors of electrical railways and tramways. (Messrs. Siemens and Halske, Germany.)

4,554. C. ADAMS-RANDALL. London. Improvements in telephony.

March 5, 1894.

4,572. C. ADAMS-RANDALL. London. Improvements in telephonic transmitters.

4,575. E. A. VAUGHTON. Birmingham. Improvements in connection with electrical tramways.

4,610. E. F. MOY. London. An improved temperature regulating device for electricity meters.

4,635. H. WEHMANN. London. Improvements in galvanic batteries.

March 6, 1894.

4,647. T. R. BURRELL and F. FOWKES. Ambleside. Improvements in electric lighting by incandescence lamps arranged in series.

4,691. A. P. LUNDBERG, G. C. LUNDBERG, and G. PEGG. London. Improvements in apparatus for connecting and disconnecting electrical circuits.

4,724. O. MARCH. London. Improvements in and relating to secondary batteries.

March 7, 1894.

4,788. F. H. NALDER, C. W. S. CRAWLEY, and A. SOAMES. London. Improvements in standard resistance boxes.

4,805. J. M. KLINGELSMITH. London. A new or improved method of lighting cycle lamps by means of electricity.

4,828. E. BÜTIKOFER. London. A combined tachometer and telemeter.

4,849. G. ST. J. DAY and S. ALLMARK. Manchester. Improvements in casings, culverts, or means for supporting and protecting electrical conductors.

4,904. R. HACKING, G. BRAND, A. G. HOWITT, and J. JOHNSTONE. London. Improvements relating to electric lamps.

4,909. G. H. COLLINS and C. S. JONES. London. Improvements in or relating to combined targets and electrical indicating apparatus.*

4,910. W. L. WISE. London. Improvements in or relating to the distribution and utilisation of electricity. (E. Modesse, Belgium.)

4,911. W. M. MORDEY. London. Improvements in or relating to electric supply apparatus such as alternators and transformers, applicable also to other purposes.

March 9, 1894.

4,945. E. G. PINK. Dublin. A combined electricity meter and automatic switch, with apparatus for registering the position of an index or pointer.

4,969. S. F. GOUGH-CALTHORPE. London. Improved device for converting and making oil lamps suitable for electric light.

4,987. E. C. DE SEGUNDO. London. An improvement in arc electric lamps.*

4,993. W. WHITEHOUSE and H. PINNELL. London. An improvement or improvements in joints for suspending electroliers.

5,001. A. ESSINGER and T. HARDEN. London. Improvements in connection with electric fuses and switches.

Digitized by Google

5,002. H. G. NICHOLS. London. Electric lamps.
5,003. J. G. W. ALDRIDGE. London. Improvements in regulating electric motors.

March 10, 1894.

5,014. W. S. RICHMOND. Suffolk. Using oil engines, gas engines, and electric engines or motors for working of capstans on fishing or other boats and cranes, &c.
5,025. M. H. SMITH London. Improvements in electric rail or tramway systems.*
5,026. R. H. BEST Birmingham. Improvements connected with the apparatus for raising and lowering the centre lights of chandeliers and electroliers, also applicable to brackets and like fittings.
5,072. G. H. Ricke London. Improvements in hangers for trolley wires.

March 12, 1894.

5,102. G. GILLMORE. Manchester. A new or improved telephonic relay.
5,118. W. E. HEYS. Manchester. Improvements in and connected with electro-locomotion on railways. (J. J. Heilmann, France.)
5,157. M. MAWSON and A. STUART. London. Improvements in apparatus for indicating the height of fluids in tanks or reservoirs by electricity.
5,158. T. J. DAWSON. London. Improvements in splice coverings for electric wires.*
5,164. A. HOFFMANN. London. Improvements relating to fittings for suspended electric lamps.

March 13, 1894.

5,194. T. R. ANDREWS and T. PREECE. Bradford. Improvements in the method of, and apparatus for, starting and stopping electric motors.
5,203. M. H. GALSWORTHY and S. S. GALSWORTHY. London. Improved electric-lit sights for night shooting on sporting rifles and other guns.
5,217. A. C. BROWN and G. R. NEILSON. London. Improvements in phonographs and appliances connected therewith.
5,226. C. P. SHREWSBURY, F. L. MARSHALL, J. COOPER, and J. L. DOBELL. London. Improvements in, or connected with, electric batteries.
5,243. A. D. LEWIS. London. Improvements in electric perforating pens.*
5,253. W. L. WISE. London. Apparatus for electric lighting, ventilating, &c., by means of storage batteries and dynamos driven from car axles or other power of varying speed. (J. N. Lewis, United States.)*
5,254. W. L. WISE. London. Apparatus for electric lighting, ventilating, &c., by means of storage batteries and dynamos driven from car axles or other power of varying speed. (J. N. Lewis, United States.)*
5,271. E. H. BROWN. London. Improvements in or connected with electric railways.*
5,273. R. W. BARKER. London. Improvements in closed conduits for electric railways. (The Lawrence Electric Company, United States).*
5,276. J. F. CUMMINGS and E. M. ENGELMAN. London. Improvements in electric railways.

March 14, 1894.

5,299. W. ROCKLIFFE, A. BEST and A. SUTHERLAND. Newcastle-on-Tyne. Improvements in the construction of brushes for preparing metals for electro-plating and for other like cleansing purposes.
5,340. J. A. FLEMING. London. Improvements in the construction of electrical resistance coils.
5,359. C. BALBIANI. London. Improvements in electrical signalling and in apparatus therefor.
5,363. T. B. GRANT. London. An improved form of alternating-current dynamo.
5,375. J. G. STATTER. London. A new or improved method of regulating or varying the speed and of twisting moment of electro motors and apparatus therefor.

March 15, 1894.

5,417. T. J. COCKERILL and W. E. BENNETT. Rochdale. A method of, and apparatus for, electrically signalling or transmitting a communication in the event of a fire or conflagration.
5,433. H. EDMUNDS. London. Improvements connected with the insulation of electric conductors of armatures or other encased, enclosed, or insulated electric conductors from which it is desirable to allow of the transmission of heat.
5,439. H. JOHNSON. London. Improvements in globes or shades for gas, electric, and other lamps.
5,442. E. P. OKEDEN, of the firm of R. Waygood and Co. London. Improvements in lifts actuated or controlled by electricity.
5,449. G. C. FRICKER. London. Improvements in connection with alternating-current dynamos working in parallel.
5,474. W. J. DAVY. London. Improvements in electric arc lamps.

March 16th, 1894.

5,508. A. MUIRHEAD. London. Improvements relating to the transmission of signals through submarine telegraph cables.
5,509. A MUIRHEAD. London. Improvements in the manufacture of submarine cables.
5,531. F. J. BURRELL. London. Improvements in dynamo supports for portable and traction engines with locomotive-type boilers.
5,537. R. HEATHFIELD and W. J. RAWSON. London. Electrical deposition of zinc and alloys of zinc and apparatus therefor.

March 17th, 1894.

5,572. F. FEARNLEY. Leeds. Elastic ear cushion for use on telephone receivers.
5,579. J. KIRKWOOD. Glasgow. Improved solutions for the electrica deposition, separation, and refinement of aluminium.
5,592. J. GRUBB and W. H. STURGE. Birmingham. Improvements in counterweights for electric light pendants and other similar purposes.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d. each.

1893.

3,477. NEHMER. Galvanic elements.

7,782. HARDINGHAM (Felten and Guilleaume). Electric cables.
8,004. DE PASS (Johannet and another). Electro-motors.
8,087. BROCKIE. Arc electric lamps.
8,315. NEW and MAYNE. Electric switches.
8,331. TYER. Electrical lock and block apparatus for railway points and signals.
9,805. SIEMENS BROS. AND CO. (Limited), and JACOB. Electric contacts.
19,146. O'BRIEN. Telephone book holders, &c.
22,765. MCCRAITH. Multiple telegraphy.
23,186. THOMPSON (Coffin). Welding pipes and tubes.
23,633. PARKIN. Electric motor.
23,744. URQUHART (Ysasmendi). Lighting railway trains by electricity.
24,392. WINKLER. Electric motors for vehicles.
24,871. JOHNSON. Dry batteries.
24,926. BRIERLEY (Weber and another). Arranging wires for electric bell, &c., circuits.
25,016. LAKE (Rand). Rosette for electric wires.

1894.

57. JOHNSTON and others. Electric motor apparatus.
95. ECKERT. Telephonic transmission.
135. PUPIN. Transmitting electric currents.
495. THOMPSON (Coffin). Transformers for electric currents.
1,003. LAKE (Johnson and another). Electric railways.
1,417. WHITTINGHAM. Starting electric motors.
1,473. LAKE (Dieckmann). Dynamo-electric machines.

COMPANIES' MEETINGS AND REPORTS.

Direct Spanish Telegraph Company (Limited).

The forty-first ordinary general meeting of the Company was held at the offices, Winchester House, Old Broad-street, on Tuesday, under the presidency of Sir John Pender, G.C.M.G., M.P.

The MANAGER (Mr. Charles Gerhardi) read the notice calling the meeting, and the minutes of the last ordinary general meeting and of the extraordinary general meeting of September 1st. These minutes having been approved as correct, the report of the Directors was taken as read.

The CHAIRMAN: I will go over the different heads of the reports and make any remarks that I consider desirable. The accounts for the half-year ended December 31st, 1893, show, after providing for debenture interest, a balance to the credit of profit and loss of £4,996 7s. 1d. The traffic receipts show a decrease of £509. 15s. 4d. as compared with the corresponding period of 1892. The decrease in traffic during the last half-year was not only due to falling off in Stock Exchange business, but also to a general depression of Spanish trade. This stagnation in Spanish business was particularly referred to at the general meeting of a bank doing a large business with Spain. I think that all who have anything to do with business, whether in Spain or in any other part of the world, must have felt that we have been passing through very severe commercial times during the past three years. They will not, however, continue for ever. I believe that the old energy, pluck and enterprise of the race still exist, but there has been such serious loss in one way and another, and such great over-production, that everything has become disorganised for the time. When,

Digitized by Google

however, you remember the enormous amount of money that is invested, and the return of interest on that money, you will see that it will only take a very short period, comparatively, to bring us back into the old state of things again. I think there is a little evidence now of an improvement in this direction, and when a better state of things does come about, you may be quite sure that telegraphy will benefit by it. Submarine telegraphy suffers less than most other businesses in a period of depression. When times are bad people require help and facilities, and they have very often to use the telegraph with a view to securing those objects. I am speaking after long years of experience, and I express my own earnest belief that we shall see good times come round again. I believe there is now some evidence of the sun beginning to shine again through the black cloud which has hung over us for so long a period. The working expenses are £35 less than those for the corresponding period of last year. It is a small sum, and is one of those changes which are incidental to this as to other companies. The greatest possible care and attention are given to keeping down the expenses in every way we can. The Company's cables, and the land-lines in connection with them, have, with one exception, continued in good working order throughout the half-year. The Falmouth-Bilbao cable became interrupted on August 16, 1893; it was, however, promptly and effectually repaired by the Eastern Company's cable ship "Electra." The cost of these repairs, amounting to £1,453. 18s. 9d., has been taken from the reserve fund. The total duration of the interruption of the Bilbao cable was only eight days, which is the shortest interruption on record as far as this Company is concerned, and the cost of the repairs is also the smallest amount incurred in restoring any of our cables. The break was occasioned by a submarine landslip or subsidence of ground. The cable, except at the place where it was severed, was found in very good condition. That is, upon the whole, satisfactory, and I may further add that the ships of the Eastern Company—which holds a very large stake in this Company—are very convenient for us in the event of any interruption taking place. A ship is always available and can be used promptly for making any repairs this Company requires; but, as I have said before, the less we are dependent on the Eastern Company or any one else for effecting repairs, the better for our interests. For the last two years efforts have been made to secure an office inside Covent Garden Market, but there was no available place. Last October, however, an opportunity was found to secure a small space in the gallery of the Foreign Fruit Auction Mart. This branch office has proved of great use, not only in securing the traffic with Spain and other places from the market, and insuring prompt delivery of the telegrams for the fruit merchants, but also as a delivery station for general messages for the West End of London. It is a very remarkable fact how the telegraph teaches people to save time when a small office is opened where there is any amount of trade carried on, more particularly with the parts which our submarine system touches; and we find that all small stations generally pick up something extra than was contemplated when establishing them. Such offices afford wonderful facilities to those who use the telegraph, and the public appreciate these facilities which encourage them to send two telegrams when otherwise they might send only one. After adding the usual sum of £2,500 to the reserve fund, the balance of profit and loss amounts to £2,496. 7s. 1d. Out of this amount the Directors recommend the payment of the dividend at the rate of 10 per cent. per annum on the Preference shares, and a dividend at the rate of 4 per cent. per annum (free of Income-tax) on the Ordinary shares, and to carry forward the balance. The reserve fund will then amount to £37,551. 11s. 10d. The rate of dividend on the Ordinary shares is the same as has been paid since July, 1891. The dividend warrants will be issued on March 31st, being payable on April 2nd, the 1st being a Sunday. Out of the reserve fund as it now stands—namely, £37,551. 11s. 10d.—the sum of £33,997. 2s. 2d. is invested in superior securities, yielding an average interest of 3½ per cent. after payment of income-tax. I think I have said nearly all that it is necessary for me to state. I have drawn attention to the leading features in the report, and I can only repeat what I have said elsewhere — that submarine telegraphy has become one of the great features in our life and one of the factors of progress, and I feel quite sure regarding the position of this Company. Although Spain is not as active as she used to be, still she occupies a very prominent and important part in Europe, and I hope that we shall see, with the revival of trade there, a considerable increase in our telegraphic communications with that country. I beg to move—

"*That the report and accounts now presented be and are hereby received and adopted.*"

Mr. EDMUND ETLINGER seconded the motion, which was carried unanimously.

The CHAIRMAN then moved that a dividend at the rate of 10 per cent. per annum (less income-tax) on the Preference shares, and a dividend at the rate of 4 per cent. per annum (free of income-tax) on the Ordinary shares, be declared, which was seconded by Mr. ETLINGER, and carried unanimously.

Mr. J. D. PENDER proposed, and Mr. DYETT seconded, the re-election of Sir John Pender, G.C.M.G., M.P., and Mr. Edmund Etlinger as Directors, and the motion was carried unanimously.

Mr. HIBBERDINE proposed the re-election of Messrs. Deloitte, Dever, Griffiths and Co. as auditors, with a remuneration of twenty guineas, which was seconded by Mr. COCHRAN, and carried.

Mr. COCHRAN proposed a vote of thanks to the Chairman and Directors, which was seconded by Mr. LOWE, and unanimously adopted.

The CHAIRMAN: I thank you on behalf of my colleagues and myself. You may rest assured that whatever we do in a financial direction for the Company we shall act with a view of improving it as much as we possibly can. I thank you very much for the confidence you repose in us.

The meeting then separated.

Eastbourne Electric Light Company (Limited).

The annual general meeting of this Company was held on Monday, at the Clifton Hotel, Eastbourne, under the presidency of Mr. Alderman George Boulton.

In moving the adoption of the Directors' report (which will be found below) the CHAIRMAN congratulated the shareholders on its very satisfactory character. For years past, he said, they had been working under great disadvantages—against apathy and powerful opposition—but these difficulties had been overcome, and he thought great credit was due to their officials for this year's report. He briefly sketched the history of the Company, and reminded the meeting of the first installation put down in 1882, under the high-tension system. It extended for only three miles, and was laid on the Parade, Devonshire-place, and Terminus-road. Now the circuit measured 7¼ miles of double cable, and 3¼ miles of single cable, or close on 18 miles of cable, with eight miles of pipes. The number of 8-c.p. lamps in circuit had risen from 2,896 in 1888 to 8,853 in 1894, and the gross earnings of the Company since 1886 had been as follows:—1886, £1,679; 1887, £2,263; 1888, £3,529; 1889, £4,147; 1890, £4,736; 1891 (five quarters), £6,753; 1892 £5,463; 1893, £6,992. That showed that they were making steady progress. One thing that had exercised the minds of the Directors a great deal was the need of extending the system to Upperton and Old Town. They believed that if this were done a large increase of business would result. But they must have money, and they proposed to raise it by Debentures at 5 per cent., the present Debenture holders having agreed that the new issue should rank with those they held. He did not like saying anything about himself, but he might tell them that so satisfied was he with the stability of the Company that he had taken £1,000 worth of new Debentures.

Mr. LANGHAM seconded the motion. He agreed with the Chairman as to the desirability of extending the system to Upperton and Old Town, and reminded them that, although the estimated cost of the extension was £6,000, that estimate included a new engine and dynamo, and meant the duplication of their machinery, which was desirable as a matter of safety for the existing system.

The motion was unanimously adopted, and a dividend of 5 per cent. free of income-tax on the share capital was declared.

Mr. J. G. Langham was re-elected a Director; and on the motion of Mr. HOLLINS, seconded by Mr. HURST, £200 was voted to the Directors for their services, Mr. Hollins pointing out that for many years the Directors received nothing, and for the twelve years the Company had been in existence they had only received £550. Messrs. Hart Bros., Tibbetts and Co. were re-elected auditors, and votes of thanks were passed to Mr. Towner and Mr. Wilkinson for their services in their capacity of secretary and electrician respectively.

An extraordinary general meeting was subsequently held, and the following resolution was adopted unanimously:—

"*That the present first Debenture issue of £25,000, bearing interest at the rate of £5 per cent. per annum, be extended with the consent of the present holders of Debentures of such issue to £35,000; and that the whole of such extended issue shall bear interest at the rate of £5 per cent. per annum, and that all the Debentures forming part of such first issue of £35,000 shall rank* pari passu, *and without priority, both as to principal and interest, whether the same shall have been issued prior to or after the date of this resolution.*"

The following is the report of the Directors:—

The gross profit for the year ended December 31, 1893, after allowing a further sum of £400 for depreciation of machinery, plant, &c., is £1,981. 2s. 2d., of which sum £1,271. 3s. 8d. has been paid for interest on debentures and mortgages, leaving a balance (including £114. 5s. 2d. carried over from last year's accounts) of £824. 3s. 8d. available for dividend. The Directors recommend a dividend at the rate of £5 per cent. upon the share capital (free of income tax), which will absorb £508. 10s. and leave a balance of £315. 2s. 8d. to meet the Directors' remuneration, and to carry forward a surplus to the credit of the current year's accounts. The reserve fund to meet depreciations now amounts to £1,425.

Last year the Directors mentioned that the extension of the circuits to the Upperton and Old Town Districts was under consideration, and as the suggestion met with the approval of the shareholders, the matter has been carefully thought out, and it has been decided to carry it out. Estimates have been prepared of the cost of the extension, and the necessary plant and machinery for working it, and these show that about £6,000 will be required. To provide this sum it is proposed to issue further debentures, bearing interest at the rate of £5 per cent. per annum. The present debenture holders have been approached upon the subject, and they have kindly consented to the authorised first debenture issue of £25,000 being extended to £35,000, so that the further monies required for the extension may rank, both as to principal and interest, equally with the debentures already issued. They, however, made it a condition that the further issue should not be placed upon the public market, but should be privately subscribed. Upwards of £3,000 has already been so subscribed, but £3,000 further is still required for carrying out the extension. The Directors consider this will be a profitable operation for the Company, and invite the shareholders to contribute to the required capital.

The Company's machinery, plant and mains are in excellent condition. Upwards of 1,300 incandescent lamps have been taken during the year, and a contract entered into with the Eastbourne Town Council for the supply of five additional arc lamps to the Royal Parade, which are now running. The number of lamps at present in use are as follows:—Arcs, 27; incandescents of ten candle-power, 8,454; as against 21 arcs and 7,136 incandescents in use at December 31, 1893.

Digitized by Google

Mr. James George Langham retires from the direction this year, but is eligible for re-election. The auditors, Messrs. Hart Brothers, Tibbetts and Co., also retire, but may be re-elected.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

ANGULAR-HOLE MACHINE COMPANY (LIMITED).—This Company has been registered with a capital of £35,000, divided into 82,000 Preference shares of 5s. each, 44,000 Deferred shares of 5s. each, and 3,500 Founders' shares of £1 each, to acquire the businesses carried on by the Square Drilling Machine Company (Limited) and the Ainley-Oakes Square Drill Syndicate (Limited).

ARDROSSAN FOUNDRY COMPANY (LIMITED).—This Company has been registered in Edinburgh, with a capital of £7,000, divided into 700 shares of £10 each, to carry on the business known as that of the Old Foundry, Ardrossan.

JOSEPH MILLS AND CO. (LIMITED).—This Company was registered on March 12th, with a capital of £2,000, in £1 shares, to acquire and take over as a going concern the electrical business carried on by Joseph Mills, at Sheffield.

KERR, STUART AND CO. (LIMITED).—This Company has been registered with a capital of £60,000, in £10 shares, to carry on business as railway carriage and waggon builders, railway and tramway plant contractors, steel rail manufacturers, locomotive builders, mechanical engineers, consulting engineers, &c.

LONDON REFUSE STEAM GENERATOR AND ELECTRICAL POWER CORPORATION (LIMITED).—This Company was registered on March 16th with a capital of £600,000, in £1 shares, to enter into and carry into effect an agreement with the Atlas Contracting Syndicate (Limited), to acquire certain patents and inventions relating to the disposal of street refuse within the district of London, and to carry on the business of mechanical engineers, boiler makers, suppliers of electricity, electrical contractors, electrical engineers, and contractors for the construction, fixing and carrying out of all necessary cables, wires, lines, accumulators, lamps and works for the generation, accumulation, distribution, and supply of electricity.

TAYLOR'S SMOKELESS BOILER SYNDICATE (LIMITED).—This Company was registered on March 10th, with a capital of £30,000, in £5 shares, to acquire certain inventions for improvements in or connected with self-contained gas-fired steam generators, for which British and foreign Letters Patent have been granted to Mr. Wilhelm O. A. Lowe, and to carry on business as metal manufacturers and merchants, mechanical engineers, machinists, metal workers, fitters, &c.

ELECTROLYTIC CAUSTIC SODA AND CHLORINE TRUST (LIMITED).—The annual return of this Company, made up to November 16th last, has been filed. Out of a nominal capital of £20,000, in shares of £10 each, 1,500 have been taken up, and 500 of these have been issued as fully paid. Upon 750 a call of £10 per share has been made, and upon the remaining 250 shares a call of £6 per share has been made, resulting in a total payment of £9,000.

ELECTRO-PROTECTOR SYNDICATE (LIMITED).—The statutory return of this Company, made up to January 29th, was filed on the 6th ult., when 7,607 shares out of a nominal capital of £10,000, in £1 shares, were taken up; 7,000 of these were issued as fully paid, and the full amount called on the remainder. The calls paid amount to £500.

ELMORE'S PATENT COPPER DEPOSITING COMPANY (LIMITED).—The annual return of this Company, made up to December 6th, has been filed. The nominal capital is £200,000, divided into 91,195 Ordinary and 8,805 Preference shares of £2 each. 91,195 Ordinary and 8,610 Preference shares have been taken up, and 23,300 Ordinary shares have been issued as fully paid. Upon the remaining 67,895 Ordinary and the 8,610 Preference shares a call of £2 per share has been made, resulting in a payment of £152,577. 10s.

ELMORE'S WIRE MANUFACTURING COMPANY (LIMITED). — The annual return of this Company, made up to December 26th, has been filed. The nominal capital is £300,020, divided into 150,000 Ordinary and 10 Founders' shares of £2 each. 67,278 Ordinary and the 10 Founders' shares have been taken up, and the full amount called. The calls paid amount to £13,137 10s., leaving £3,953 10s. unpaid. No less than 1,610 Ordinary shares have been forfeited, together with £515 paid in respect thereof.

ESTON ARC LAMP SYNDICATE (LIMITED).—In reply to inquiries, the solicitor states that the Company did not go to allotment, and no business of any kind has ever been done. The name of the Company is to be struck off the register.

FIBRITE SYNDICATE (LIMITED).—This Company, although incorporated in September, 1891, has never filed any returns, and will be struck off the Register of Joint Stock Companies should the same not be forthcoming.

FOREIGN AND COLONIAL ARC ACCUMULATOR COMPANY.—An agreement dated March 6, 1894, between the above Company, William Wright, and William Baker (executors of Anthony Reckenzaun, the inventor of the patents to be sold to the Company), Henry Edmunds, and Robert W. Winthrop, provides for the allotment of 331 fully-paid shares to William Wright and William Baker, and of 662 fully-paid shares to Robert W. Blackwell (who has bought Henry Edmund's interest) in consideration for the sale to the Company of certain Belgian, French, Australian, and United States letters patent for "Improvements in the manufacture of plates for secondary batteries."

FOWLER-WARING CABLES COMPANY (LIMITED).—The annual return of this Company, made up to January 26th, has been filed. Out of a nominal capital of £200,000, divided into 39,700 Ordinary and 300 Founders' shares of £5 each, 20,000 Ordinary and the Founders' shares have been taken up, the latter being considered as fully paid. The full amount has been called and paid on the 20,000 Ordinary shares.

GORDON ELECTRIC TRACTION SYNDICATE (LIMITED).—The annual return of this Company, made up to November 28th, has been filed. The whole nominal capital of £2,400, in shares of £10 each, was taken up. Of these shares 60 have been issued as fully paid. The full amount of £1,800 has been called and paid on the remainder.

HOPE-JONES ELECTRIC ORGAN COMPANY (LIMITED).—The annual return of this Company, made up to November 14th, has been filed. The nominal capital is £25,000, divided into 1,200 Preference and 1,300 Ordinary shares, of which 695 Preference and 1,300 Ordinary have been taken up, all the latter being issued as fully paid to the vendor and Thomas Threlfall. Upon the 695 Preference shares, the full amount has been called, resulting in the payment of £6,910, and leaving £40 in arrears.

J. E. HOPKINSON AND CO. (LIMITED).—The first annual return of this Company, made up to February 19th, has been filed; 13,007 shares were taken up, and 10,000 issued as fully paid. Upon the remaining 3,007 shares the full amounts have been called and paid.

LAURENCE, SCOTT AND CO. (LIMITED).—The annual return of this concern, just filed, states that of 1,406 shares out of a capital of £30,000, in £10 shares, 500 have been issued as fully paid, and the full amount of £9,060 has been paid on the remainder.

LONDON ELECTRIC WIRE COMPANY (LIMITED).—The annual return of this Company, made up to February 9th, has been filed. The nominal capital is £50,000, divided into 5,000 Preference and 5,000 Ordinary shares of £5 each, and 4,188 Preference and 4,597 Ordinary shares have been taken up; 3,860 of each class have been issued as fully paid, and the full amount has been called on the remaining 328 Preference and 737 Ordinary shares, resulting in the payment of £5,325.

CITY NOTES.

CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).—Letters of allotment for the recent issue of Six per Cent. Preference Shares in this Company have been posted.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended March 18th were £926, as against £880 in the corresponding period of last year, being an increase of £46. The total receipts for the half-year amount to £10,400, as against £10,412 for the corresponding period of last year, a decrease of £12.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY, LIMITED.—Notice is given that the eleventh drawing for payment of the 5 per cent. Australasian Government Subsidy Debentures, will take place on Monday, the 2nd April, at 11.30 a.m., at the offices of the Company, Winchester House, E.C. 371 debentures are to be drawn.

GREAT NORTHERN TELEGRAPH COMPANY.—The ordinary general meeting of this Company is to be held at the Exchange, Copenhagen, on Saturday, the 21st April, at 3.15 p.m.

HOVE ELECTRIC LIGHTING COMPANY (LIMITED).—This Company is making a public appeal for further capital to the extent of £12,500 in Five per Cent. First Mortgage Debenture Bonds.

LONDON REFUSE STEAM GENERATOR AND ELECTRICAL POWER CORPORATION (LIMITED).—A prospectus has been issued inviting applications for shares in this Company, which has a capital of no less than £600,000, in £1 shares. The prospectus states that the Company is formed to acquire the Livêt patents for destroying town refuse, and for the economical and rapid generation of heat in furnaces for electric lighting and other purposes. *The Electrician* for February 16th contained particulars of this system. It would appear that if success attends the launching of the present Company, provincial companies will be formed for working these patents. It is difficult to believe that the Company will be able to earn a dividend on so large a capital in London alone, although the prospectus is crowded with sanguine anticipations. No less than £400,000 is to be paid for the patents which the Company is to acquire. Seeing that the Company may shortly have to share the field with a competitor for which many advantages over the Livêt system are claimed, the investment appears decidedly risky.

WATERLOO AND CITY RAILWAY COMPANY.—The prospectus has been issued this week of this Company. A tunnel line is to be built between Waterloo station and a point nearly opposite the Mansion House, and the motive power used will be electricity. This will give the London and South-Western Railway a much-needed station in the heart of the City. Several of the South-Western Directors are on the Board of the new Company, and the former guarantees a minimum dividend of 3 per cent. out of gross receipts, two-thirds of the net profit also to go to the Waterloo and City Company. The share capital is £540,000.

Digitized by Google

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended March 16th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited) were £3,550.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the two weeks ended March 15 were £2,824, as compared with £3,013 for the corresponding period of last year. The November receipts, estimated at £4,577, realised £4,615.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 828.—Vol. XXXII. FRIDAY, MARCH 30, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

A few weeks ago the Waterloo and City Electric Railway came before the public under the ægis of the London and South-Western Railway Company; and this week the Charing Cross, Euston and Hampstead Railway Company invites subscriptions towards its authorised share capital of £1,416,000, and does so without any ostensible backing, other than the intrinsic merits of the proposed method of construction and working, and the need which exists for such a railway. The line of route is from the Strand, near King William-street, along Charing Cross-road, Tottenham Court-road, Hampstead-road, High-street, Camden Town, Haverstock Hill, to High-street, Hampstead, within five minutes' walk of Jack Straw's Castle; with intermediate stations at Oxford-street, Euston-road, Seymour-street, Camden Town, Chalk Farm and Belsize-park. Hampstead proper, so far as "rapid transit," is concerned, is practically isolated from the West End, and a convenient means of communication will no doubt be much appreciated. The wretched "yellow 'bus" service which infests the streets over part of this route is a disgrace to London, and the fares are higher—that is to say, a penny goes a fewer number of yards—than on any other Metropolitan line. The railway route, moreover, traverses a densely populated industrial quarter, and should secure a large holiday and Sunday traffic whenever meteorological conditions are favourable. The promoters state that it is intended to run "light trains at short intervals," and a 2½-minute service is promised. This looks as if the Liverpool Overhead Railway arrangements, rather than those of the City and South London Line, were to be the pattern. It is to be hoped this will be the case. Our railways suffered somewhat in their early days by following too closely on the lines of the old mail coaches, and those responsible for our electric suburban "undergrounds" will do well to avoid a similar mistake, and to disabuse their minds of the idea that they are building railways, when, as a matter of fact, they are constructing glorified tramways. Railways on our well-developed railway system are well adapted for communication between town and country, or between town and town; but the traffic from one part of a city to another should be arranged on a different principle.

The success which has attended the experiment at the works of Messrs. Mather and Platt has already given a great impetus to the eight-hours' movement, and is destined, we doubt not, to give it a still greater impetus. The experiment was, of course, carried out under exceptionally favourable, though not under artificially favourable, conditions; for it is not every firm that has 1,200 men in its employ engaged in such a wide variety of manufacture, and possesses such an admirable organiser as Mr. William Mather. On the other hand, it must be remembered that the past twelve months have been a period of almost unexampled trade depression, and it is to be noted, moreover, that although every effort was naturally made on either side to ensure the success of the experiment, no conditions were introduced which would not obtain in everyday practice. The net outcome is that the ratio of wages to turnover has increased by 0·4 per cent., as compared with the average of the six preceding years, when better prices ruled; and this increase is exactly balanced by the decreased cost of lighting, fuel, and general wear and tear. Men on piece-work, who might reasonably have been expected to lose considerably by an eight hours' day unless their wages were raised, have in twelve months nearly managed to make up for shorter hours by increased energy. Last, but not least, the proportion of "time lost without leave" to the total time worked has been reduced from 2·46 per cent. to 0·46 per cent. The results obtained at Salford are, perhaps, too good to be reached everywhere else at a bound, but they show that the eight hours' day is not incompatible with our commercial supremacy, and Mr. Mather's report should for ever dissuade Parliament from attempting to legislate mankind into rigid uniformity.

The dispute between the London County Council and the London Street Tramways Company, as to the terms upon which the latter undertaking is to be purchased under the Tramways Act of 1870, is of some interest to electric light undertakers, inasmuch as the purchase clause of the Electric Light (Amendment) Act of 1888 is much on the same lines as the 43rd section of the Tramways Act. Fortunately for those who have invested their money in electric light undertakings, the terms upon which these are to be bought up are far more explicit than is the case with tramway undertakings. The fight now going on in the Court of Appeal, which will in all probability be carried to the House of Lords, relates to the meaning of the expression "the then value of the tramway," the County Council taking it in its plain English sense as the cost of construction less depreciation, whilst the Company

Digitized by Google

takes the view that the then value is to be arrived at by finding what the average earnings of the tramway are, and then allowing so many years' purchase; in which contention the Company has been upheld by the Divisional Court.

THIS particular ambiguity does not appertain to section 2 of the Electric Light (Amendment) Act of 1888, in which it is stated that the then value is to be deemed to be the fair market value of the property of the Company, taking into consideration its nature, condition, suitability to the purposes of the undertaking, and the fact that the plant is in a position ready for immediate working. This explanation, together with the express exclusion of any allowance in respect of compulsory purchase, goodwill, or past or prospective profits, does not seem to us to admit of much doubt as to the basis upon which the arbitrator of the future will estimate the money to be paid by local authorities to Electric Lighting Companies when the former purchase the undertakings of the latter. The terms are no doubt unwisely severe, and are, therefore, open to the objection that they tend to stifle individual enterprise, one of the mainsprings of national prosperity, but with the terms of purchase so clearly set forth, there can be no justification in this instance for the use of that much favoured word "confiscation."

THE *Physical Review* contains in its current number several Papers of interest. Prof. CARHART sends a record of careful experiments carried out for the purpose of confirming or refuting the conclusions of Mr. SANFORD on what he called a necessary modification of OHM's law. We were unable to accept those conclusions, which related to the electrical resistance of wires in dielectric liquids or vapours, and pointed out that the observed effects might very well have been due to changes of temperature. Prof. CARHART's students have repeated the experiments with sensitive apparatus, and have failed to discover any differences too large to be accounted for by errors of observation. A Paper by Mr. E. S. FERRY in the same number describes a series of photometrical experiments with rotating sectors, and arrives at the conclusion that this well-known device for reducing illumination is subject to considerable error if the two lights under comparison differ in colour composition, and if the total aperture between the rotating sectors is less than the area of the sectors themselves. Curves are given, of three sets of tests, showing errors which increase rapidly from about 1 per cent. for 120° total aperture to 4 to 7 per cent. for an aperture of 60°, and from 10 to 15 per cent. for an aperture of 24°. By "errors" the author means the difference between readings obtained by cutting off the more powerful illumination by means of the rotating sector (the photometer box being at the middle of the bar), and by the ordinary method of moving the photometer box. He therefore assumes that his photometer, which is a modification of the Ritchie arrangement, is perfect. With two lamps, the one of 150 c.p. and the other of 13 c.p., and the two identical monochromatic lights, no "error" was found; but the difference was observed when the lamp behind the revolving sectors was forced, that is, when it gave a larger proportion of blue rays than the other. The error is attributed to the lower luminosity of the more refrangible rays. The sectors used by Capt. ABNEY and Gen. FESTING consisted, if we remember right, in two openings of 90°, which can be reduced to nothing by means of adjustable sectors. Before this difference can be attributed to the revolving sectors as an error, comparisons should be made with many different kinds of photometers, and perhaps, with different modes of producing regular and periodic variations and extinctions.

Electrocution.—The dynamo for the electrocution of criminals at Sing Sing has been rewound to give 2,500 instead of 1,000 volts.

Prof. Kennedy.—The Senate of Glasgow University have decided to confer the honorary degree of LL.D. on Prof. Alexander B. W. Kennedy, F.R.S., Emeritus Professor of Engineering in University College, London.

Electric Launches at Bergen.—A Company has been formed at Bergen, says *Engineering*, for the purpose of running electric launches in the harbour for passenger traffic. The plan is to start with eight launches, and to commence running them in June.

Société Internationale des Électriciens.—The legacy of 100,000fr. placed at the disposal of the French Government by the late M. Giffard has been given by the Minister of Public Instruction to the Laboratory of the Société Internationale des Electriciens.

Personal.—Lieut. M. C. Maunsell, R.A., has been appointed Instructor in Electricity at the Royal Military Academy, Woolwich.——Dr. S. Rideal has fitted up laboratories at 28, Victoria-street, Westminster, S.W., in order to facilitate the execution of his analytical and consulting work.

Tram-Car Lighting.—The London Tramways Company is experimenting with an electrically-lit tramcar, on the Westminster and Streatham-hill line. Power is carried in secondary batteries, and the roof of the car is lit by two glow lamps placed in stout structures at each end of the roof. It is said that on any part of the roof the smallest print can be read in the light thus obtained.

Electrically-Driven Machine Tools.—An Exhibition of electrically-driven machine tools is to be held at Buda-Pesth from May 27 to September 30, 1894. Current for working the machines will be supplied, and plant not sold will have the return freight paid on it by the management of the Exhibition. Full particulars can be obtained from Mr. Charles Rath, Director of the Hungarian Commercial Museum, Buda-Pesth.

Electro-Medical Experiments.—Prof. Yarchanoff, of St. Petersburg, finds that if he attaches the terminals of a very delicate galvanometer to the skin in different parts of the body, and then either acts on the nerves of the skin, by means of a brush or needle prick, or acts on the nervous system generally by means of sound, light, taste, or smell, or even by blinking the eyes, a considerable deflection of the galvanometer is produced.

The Belknap Woven Wire and Graphite Brush.—A dynamo brush has recently been placed on the market by the Belknap Motor Company, of Portland, Me., which is a combination of graphite and copper wire cloth. The copper wire is made of selected copper, woven after a special pattern into cloth. The inner folds of the cloth are treated with a compound of graphite so that as the brush wears, the graphite furnishes the lubrication for the commutator.

The Rating of Electric Lighting Undertakings.—The financial progress which so many electric lighting companies are making is beginning to excite the attention of the rating

Digitized by Google

authorities, with the result that assessments, in some instances of a most unreasonable character, are attempted to be put into force. The Eastbourne authorities some time ago raised the assessment of the Eastbourne Company from £150 to £795. No doubt some increase in the assessment was warranted by the progress the Company had made, but the Machinery Users' Association advised that the large increase was altogether unjustifiable, and the result of the appeal has been a reduction to £525, or about two-thirds. In another case, also conducted by the same Association, the Preston authorities have now offered to reduce the assessment of the National Electric Supply Company, from £1,095 to £675, but this offer has been declined, and an appeal to Quarter Sessions is intended.

Dividends, Gas and Electric.—In a letter to *The Times* on the commercial progress of electricity, Major Flood Page writes:—"I can well believe that our gas company friends may say I am easily satisfied, that our dividends are paltry, that we live on hope, and, in the assurance of their own steady dividends, can laugh and pour contempt on our humble efforts. But our progress has been phenomenal when compared with that of gas. On May 13, 1879, Mr. Corbett Woodall, M.I.C.E., engineer-in-chief of the Phœnix Gas Company, gave evidence before the Parliamentary Committee to which I have already referred and said, 'As a rule in early years gas companies did not pay any dividend at all, or a very small one. Before coming away I sought to find the dividends paid by my Company since 1824. I was unable to find them up to 1851, but I believe they never reached 3 per cent. before 1851.' That is, for 27 years. Surely we have good ground for hope."

The Bolometer.—In the report of the Smithsonian Institute for the year ending June, 1893, it is stated that Prof. Langley has continued his important investigations with the bolometer. The instrument, as now constructed, is a minute strip of metal barely $\frac{1}{500}$ of an inch wide, and less than $\frac{1}{5000}$ of an inch thick. Through this thread of metal a current is continually kept flowing. When the spectrum, visible or invisible, is thrown upon it, the thread is warmed and the resistance increased by an amount corresponding to the intensity of the effect received, while instruments specially mounted and constructed are in electric connection with the thread, and now automatically record every minute change in the current. With late improvements these instruments are so delicate that a change of temperature of one-millionth of a degree is readily detected and even measured, and it is easy to see that, as a consequence of this delicacy, the greatest care must be taken in their use.

Viscosity Test.—For testing the viscosity of lubricating oil, the following apparatus is in use on the Philadelphia and Reading Railroad. A cylinder, 2 in. by $1\frac{1}{2}$in. long, is suspended in the oil to be tested, by means of a fine steel wire attached at its upper end to a knob inserted in a stiff frame. By twisting this knob the wire can be subjected to torsion. About the middle of its length the wire has attached to it a horizontal disc, graduated in degrees, which rotates with the wire when the latter is turned, and serves to measure the angles of oscillation. In making a test the oil is surrounded by a bath of water or paraffin to bring it to the required temperature. The disc on the wire is clamped, and the knob at the top turned through an angle of 360°. The clamp holding the disc is then released, and the torsion in the wire causes the cylinder immersed in the oil to move through angles which become less at each succeeding oscillation. These angles are measured by the disc, and form a criterion of the viscosity of the oil.

Electrical Communication with Lightships.—On Saturday morning telephonic communication was opened up between the North Goodwin lightvessel and Ramsgate. In this case the distance is much shorter than that between the Kentish Knock and the shore, being only a little over five miles; but, as this lightship practically commands the Goodwin Sands, her electric connection is likely to prove of much service in affording the means of giving information at the earliest possible moment of casualties in the vicinity of the sands. The arrangements for carrying the electric cable clear of the ship's moorings are in all respects similar to those adopted for the Kentish Knock. The electric cable is taken ashore at Dumpton Gap and then connected with the Ramsgate Post Office. The ships engaged in completing this second lightship were the Post Office cable-ship "Monarch" and the Trinity steamers "Vestal" and "Warden." The Goodwin lightvessel is probably the most perfect and complete specimen of a lightship afloat.

A Big Opening for Small Arcs.—The enormous importance of the ease of sub-division which was afforded by the invention of the glow lamp, says the *Electrical Engineer* of New York, under the above heading, "can be no better brought home to economists than by adverting to the well-known fact that for the same amount of electrical energy expended, the arc lamp produces 10 times as much illumination as the incandescent lamp, and yet the incandescent lamp has triumphed. With this condition of affairs confronting us, it requires no great amount of discernment to predict that the next step towards improvement in arc lighting must be in the direction of arcs of small power, say, from 50 c.p. up." Our American contemporary then proceeds to pin its faith on the "Howard arc enclosing cylinder," which we gather is a device for reducing the rate of consumption of arc light carbons, and points out what can be done in the way of arc lighting on constant potential circuits by instancing the 2,700 lamps now burning in Brooklyn, with 400 more waiting to get on the central station circuit.

Royal Institution.—We have received further particulars of the arrangements for lectures at the Royal Institution during the present session. The following lectures on electrical and allied subjects will be given on Friday evenings:—"Electric Discharges Through Gases," by Prof. J. J. Thomson, on April 13th; "The Splash of a Drop and Allied Phenomena," by Prof. A. M. Worthington, on May 18th; "The Work of Hertz," by Prof. O. J. Lodge, on June 1st; and "The Newtonian Constant of Gravitation," by Mr. C. V. Boys, on June 8th. Courses of lectures will be delivered during the session as follows:—Four lectures on "Electric Illumination," by Prof. J. A. Fleming, on Tuesdays, April 3rd to 24th; three lectures on "The Modern Microscope: an Instrument for Recreation and Research," by the Rev. W. H. Dallinger, on Tuesdays, May 22nd to June 5th; three lectures on "The Solid and Liquid States of Matter," by Prof. Dewar, on Thursdays, May 3rd to 17th; and three lectures on "Colour Vision," by Captain Abney, on Saturdays, May 5th to 19th. The lectures on Fridays commence at nine o'clock in the evening, and the lectures in the courses commence at 3 p.m.

Electric Motors on H.M.S. "Barfleur."—On Saturday, the 10th instant, the battleship "Barfleur" went through her trials. The gun mountings and barbettes of the "Barfleur" are precisely of the same character as those of her sister ship "Centurion," which were tested at Portsmouth on January 4th. In view of the long-expressed desire to simplify as much as possible the handling of the guns, the primary principle of the design has been hand operating throughout; but, as in this case the extreme range of elevation from −7deg. to +35deg. gives a large angle to work through, Messrs. Whitworth and Co. have, in conjunction with Messrs. Siemens Brothers, applied electric motors for the purpose of elevating the gun and actuating the ammunition hoists as an auxiliary to the original hand-power. The trial of these motors attracted considerable attention, as the "Barfleur" and "Centurion" are the first English ships on which such motor appliances have been introduced for operating large guns. The "Capitan Prat" for Chili and the "Jauréguiberry" for the French Government, as well as the "Latouche Tréville" and her sister ships, have been or are being fitted with electricity as a motive power. The current is taken from the electric lighting main. The motors are "ironclad" and watertight. There is a motor provided for each operation—one under the sighting stations for elevating the gun, and connected by gearing with the hand-elevating appliance; while another is placed on the turn-table, and works the ammunition hoists. By means of the electric motors the guns can be moved through the angle of 42deg. in 14sec., and the charges brought to the rear of the gun in 19sec. The motors were used in the fore-barbette on Saturday with such satisfactory results as to afford a promise of their extension to all guns of a like nature.

Sheffield Electric Power Station.—Last Saturday week the new electric power station of the Sheffield Electric Light and Power Company was formally opened. The station is erected in three spans, covering an area of 2,060 square feet. Two spans are allotted to the engines and dynamos, the third forms the boiler house. The walls are lined inside with glazed brick. The present plant includes four Mordey alternators, rope-driven from separate vertical steam engines. In the boiler house there are five Babcock-Wilcox boilers, each capable of evaporating 5,000lb. of water per hour. The tubes are of Mannesmann weldless mild steel, instead of the usual lap-welded wrought-iron type. There is also an economiser which will deal with 3,000 gallons of water per hour. Over the boiler house is erected a tank holding a reserve of 20,000 gallons of water. At one end of the boiler house is a horizontal compound jet condensing engine belted to a countershaft supplying power to three Thomson-Houston arc lighting machines. Each machine will maintain 50 10-ampere lamps in series. The steam mains are 15in. internal diameter, and of wrought steel lap-welded, and are in duplicate. All the engines exhaust into a main exhaust trunk, 12in. diameter, to which is attached an independent condenser. Any engine may be shut off from the exhaust trunk, and relief valves are provided for the engines to exhaust into atmosphere if required. All the alternator fields are excited in parallel. Each exciter carries its own automatic switching gear and electrical governor. All the alternators feed into one pair of bus mains. Each alternator has its own synchronising pillar, with switching gear. The primary circuits are concentric, insulated with vulcanised rubber, and drawn into 3in. cast iron pipes. The arc light circuits are concentric and of paper insulation lead covered. The secondary circuits are laid in iron troughs, and filled in with solid bitumen.

Petroleum in Somersetshire.—It is now some time, says the *Engineer*, since paragraphs began to appear in the daily press concerning the find of petroleum in Somersetshire. The presence of petroleum in the house well at Ashwick, which has suddenly found itself famous, is no new thing. The first considerable outburst which received attention was during the long drought of last year, and immediately subsequent to a slight earthquake shock. Evidence of the occurrence of this outburst has been collected in as trustworthy a form as possible. The spirit of impartial inquiry in which the investigation was conducted was rendered specially necessary by two facts, viz., that the well is situated in strata not usually considered to be petroleum bearing, and that the oil itself is not of the quality commonly characteristic of crude petroleum. The whole matter first passed into expert hands when a small sample of the oil was submitted to Mr. Boverton Redwood some months ago. With regard to the geological situation of the oil, it may be said that the carboniferous limestone in which the oil is found has not hitherto been identified with the occurrence of petroleum. The chemical characteristics of the oil are also different from those of most crude petroleum, the samples examined more nearly resembling a distillate of the crude oil than crude oil of normal quality. The high specific gravity and flashing point of the oil detract somewhat from its value as an illuminant. In spite of this drawback, it is probable that in distilling the oil some 75 per cent. of good burning oil could be obtained. Moreover, there is an increasing demand for high-flash petroleum for small motive power. Of the good quality of the Ashwick oil there can be no doubt, and the value of its discovery consequently depends upon its abundance. With all the facts before us we are of opinion that the quotation of English petroleum in "prices current" is a somewhat remote contingency, but that no stone should be left unturned to bring that possibility about.

Electrically-Actuated Valves.—In an interesting Paper on "Artificial Refrigeration through Street Pipe Lines from Central Stations," which recently appeared in the *Journal* of the Franklin Institute, the author, Mr. Branson, expresses himself as follows:—"In the matter of automatic control we had to solve the problem of supplying all degrees of temperature, not only on the same branch line or street, but often three or four in one building, or even in the different compartments of one refrigerating box, varying from ice-making and fish-freezing up to the very easy task of keeping rooms for furs and woollen goods free from moths, or taking a few degrees of heat and humidity from a restaurant dining-room, a public hall, business office, or hospital. To do this, numerous devices were invented and tested—nearly all with brilliant success at the start, only to be followed by dismal failure when put to the test of time and innumerable changing conditions. They choked up, froze up, gummed up, and broke up in every imaginable way. But one by one the weak points were weeded out, the strong features combined; until, finally, two forms of regulators were constructed, both of which have stood the test of every possible condition we could think of through the changing requirements of spring, summer, autumn, and winter. These automatic valves are operated by electric power supplied from a dynamo through a storage battery at the central station; thence through an insulated copper wire circuit laid in the same conduit which contains the pipe line, and they are caused to open and close by the action of an ordinary thermostat placed in the cooling box and easily adjusted by thumb screws to any required temperatnre. We ordinarily set them to open the valves at 1deg. above and close them at 1deg. below the average temperature required; though, with careful manipulation, they can be adjusted so as to permit of much less variation. In the preservation of eggs, for instance, we do not permit a variation of more than one-half of 1deg.; and, as a consequence, have had remarkable success in the preservation of this most perishable product. In connection with the automatic valve the electric circuit can be used to signal from any refrigerator on the line to the engineer at the station; and one form of valve is so constructed that, if it should get out of order, an electric bell would ring in the engine room until the valve is attended to."

The Use of Electricity in Metallurgical Operations.—In a recent number of the *Comptes Rendus*, M. Jules Garnier states that he has carried out in the workshops of M. Hillairet some experiments with a view to utilising electricity for the purpose of observing the various phases of certain metallurgical operations, and, thinking his method might be generally applicable, he gave the following account of it to the Académie des Sciences:—I placed in a tube of refractory earth some powdered oxide of nickel mixed with charcoal, two soft steel rods penetrated into the tube at either end, pressing the mixture, the thickness of which was a few centimetres, between them. This arrangement was placed horizontally in a small reverberatory furnace heated by coke, whilst the two steel rods formed part of an electric circuit. At first the resistance offered was perfect, the current being zero with the voltmeters 50, but after 15 minutes heating, the needles began to move, the current gradually rising, and the voltage diminishing so that at one time there were nearly 50 amperes passing, and hence next to no resistance. After remaining steady for an instant in this position, the needles of the ammeter and voltmeter slowly returned towards their original position, finally becoming steady at one or two amperes, at about 45 volts. These variations of the current first in one direction and then in another exhibited the reactions which went on in the mixture of oxide of nickel and charcoal. To begin with, the mixture stopped the passage of any current; at the moment when the oxide was beginning to be reduced to the metallic state, the current flowed at first feebly, then more and more freely so that at the precise moment when the reduced nickel formed a sort of interrupted chain from anode to cathode, the voltage was zero. It was then that the carburisation of the metal began, a phenomenon was exhibited on the voltmeter and ammeter by the reverse movement of their needles. The resistance, indeed, became considerable at the moment when the particles of carburetted nickel, which are easily fusible, united together in globules. In another experiment, in which I operated on a mixture of oxide of copper and nickel of iron, in spite of the complexity of the mixture, the variations in the current only showed the successive phases in the reduction of the three metals. One of the consequences to be drawn by these experiments is that we can follow electrically the progress of a certain number of metallurgical operations, especially the refining of metals, the conducting powers of which vary as their composition is altered.

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(Continued from page 519.)

Compensators or Regulators.

The Thomson-Houston Company use in particular cases a compensator, whose functions are similar to those of the "regulator," referred to in a previous portion of this series, with two-wire continuous-current feeders and multiple-wire distributors. It may be of use for power work in cases where the regulation of the supply pressure presents difficulties. The plan of connection is shown in Fig. 91, the "compensator" being simply a choking coil with its circuit divided into as many parts as there are sub-circuits. Each of the distributing circuits are assumed to be at 125 volts.

When the load is evenly divided between the circuits the choking coils will carry practically no current, owing to the impedance of its coils which are wound round soft iron wire. But if the load be removed from one of the four circuits, the compen-

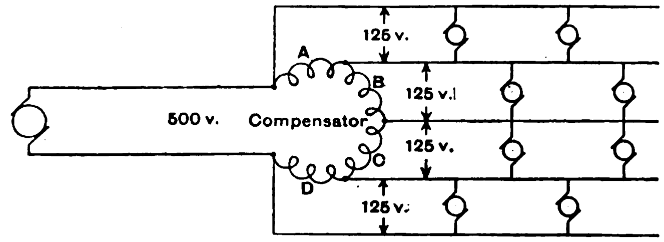

FIG. 91.—Prof. Elihu Thomson's "Compensator" system applied to a Power Circuit.

sator coil, say coil A, in parallel to it will act as the primary of a transformer, and induce in the remaining coils of the compensator B, C, D, a secondary current in the same direction as the main current. In this particular case the ratio of conversion will be 1:3, and therefore the coils B, C, D will supply $\frac{i}{3}$ amperes, i being the current for two motors (assuming them to be equally loaded), and the alternator will supply $\frac{2}{3}\,i$ amperes. If the two circuits A and B were opened then the coils C and D would supply $\frac{i}{2}$ of the current, and the alternator an equal amount. The regulating capacity of the compensator is therefore seen to be in this case equal to four times the current it is designed to carry. It is evident that small differences of load between the various circuits are readily compensated by this ingenious device, which may be defined as a combination of a transformer and a direct system of distribution.

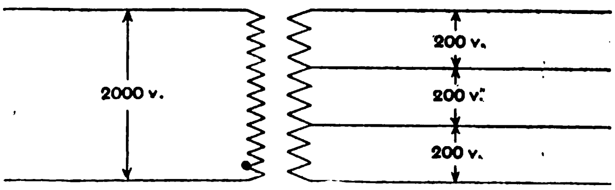

FIG. 92.

As far as the author is aware this method of multiple-wire distribution with alternate currents has not been applied to power work, although it has been used to some extent for lighting in America. The evident objection to it is that it brings the high pressure of the primary circuit into the consumers' premises, and, therefore, constitutes a source of possible danger. A better arrangement for power work, when it is desired to use a multiple-wire distributing system, is to divide the secondary circuit of a large transformer at the sub-station into as many circuits as may be required, and at suitable pressures for the work (they need not be of the same value) *see* Fig. 92. This separates the high-pressure mains from the distributing circuit, and the total secondary pressure can be made of any desired value. A transformer thus loaded will work as well as if the secondary circuit were not divided, and it will maintain the same ratio of pressure between the distributors, neglecting the drop due to the resistance, if the primary circuit, as a whole, adjusts the power according to the output. Difficulty, however, may be found if more than one transformer be used unless both the primaries are coupled in parallel, and also both the secondaries; or better still if the primaries are coupled in parallel, and the secondaries in series. This latter arrangement requires for four-wire distributors three transformers, the middle wires being coupled to the junctions of the secondaries.

It must be understood that these proposals offer no advantages as regards the transformers, they simply permit the use of a multiple-wire distribution, which is a point of some importance in power work.

Coupling Free-running Alternators in Parallel.

Before an alternator is coupled parallel it should be ascertained to be as nearly as possible in step with those already in circuit. The practical methods of judging this condition vary with the types of machines and their relative sizes and speeds, but in most cases there is no difficulty. If the alternators are of similar make, all that is necessary is to raise the pressure to the omnibus voltage and to notice that the frequencies are approximately the same before closing the

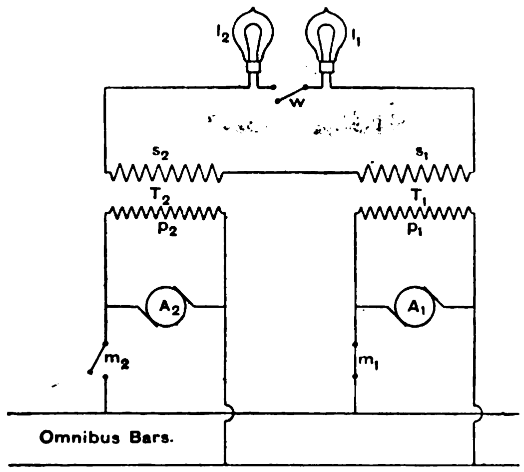

FIG. 93.—Diagram of Phase Indicator or Synchroniser.

parallel switch. At the instant of making circuit, there may be a comparatively large rush of current and then the bank of alternators will drop into step and the load may be adjusted between them, if necessary, by their excitation. The author has seen Mordey and Gülcher alternators put parallel without further precautions; but, of course, the lamps pulsated until the machines were in step.

It is customary, however, in most lighting stations to use a phase indicator. This consists of two transformers, one of the primaries being coupled to the alternator running the load, and the other to the incoming machine. The secondary circuits are coupled in series with two incandescent lamps of suitable pressure. The arrangement of details is as shown in Fig. 93.

The procedure is usually as follows:—The incoming alternator, A_2 say, is run up to proper speed and its field excited, so that it gives the terminal pressure of the omnibus bars. Sometimes it is coupled to the station lamps or an artificial resistance, but this is not essential in most cases. The synchroniser switch W is then closed, and the lamps l_1 and l_2, being fed with the joint currents from the transformers T_1 and T_2, will be black or luminous, according as the alternators A_1 and A_2 are in similar or opposite phase. The instant the two are in step the lamps will become steadily black or luminous (according to the coupling up of the secondaries), and then the main switch m_2 may be closed without disturbing the lamps on the outer circuit. During the short interval of time required for the machines to get into step, the lamps pulsate with luminous

"beats" as the lagging machine overtakes the leading one. The synchroniser can be coupled successively to any pair of the alternators.

It is found convenient with the Ganz alternators, and most of the Continental alternators, to run the incoming machine on an artificial load to approximately the same current as it is required to give on the main circuit before using the synchroniser, and closing the main switch. This precaution seems to be only necessary with armatures of large self-induction, in which the terminal pressure varies considerably with changes of current. In England it is not customary to use an artificial load.

The Thomson-Houston Company insert a variable impedance coil in the armature circuit of the incoming alternator in order to check any in-rush or out-rush of current. The method of using these impedance coils with the synchroniser is shown in Fig. 94.

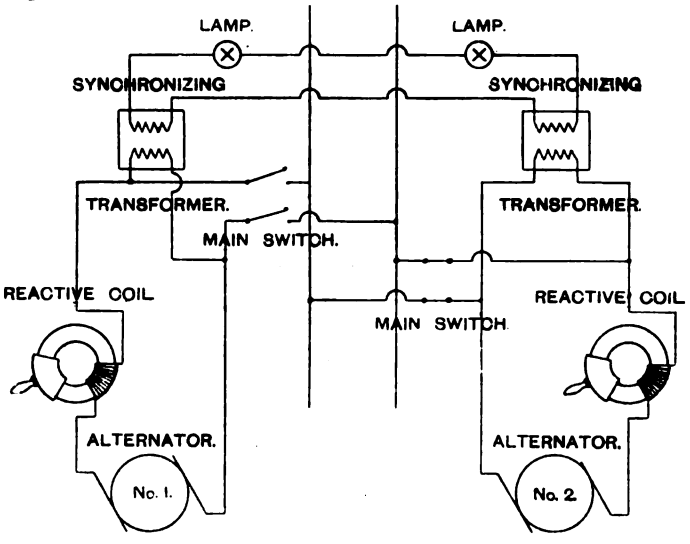

FIG. 94.—Arrangement of Reactive Coils, used in putting Thomson Alternators in Parallel.

The impedance coil is shown separately in Fig. 95. It consists of a laminated iron ring, with a few turns of well-insulated wire wound round about one eighth of the circumference. A copper sheath is arranged so as to be capable of rotation about the centre. The sheath is of such width as just to surround the coil. When the winding is covered, the device corresponds to a transformer with the secondary circuit short-circuited, and the impedance is then very slight; as the sheath is gradually removed the impedance increases; when the stationary coil is entirely uncovered the device has its maximum effect. In some forms the impedance coil is short circuited when the sheath completely encloses it These impedance coils are useful for balancing loads between machines, varying the pressure of feeders, and generally act the same as rheostats with continuous currents; but have the advantage of consuming less power.

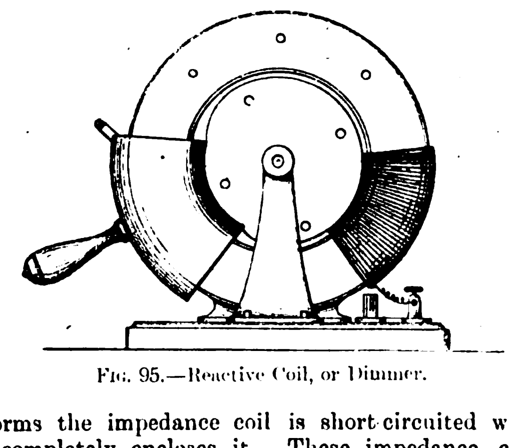

FIG. 95.—Reactive Coil, or Dimmer.

Parallel working is without doubt assisted by using a moderate rate of frequency, say, not more than about 100 ∿. but there is no gain in reducing it below about 50 to 60 ∿, It is also necessary to synchronise the engines as well as the alternators if the running is to be perfect. This points to high-speed engines with flywheels and moving parts of small inertia, so as to readily lead or lag as the conditions of working may require. For the same reason the engine should not be governed directly, as the better the governor the greater the difficulty of varying the rate of speed. The station governor should be designed to control the steam admission to the bank of engines, and the load should be distributed proportionately by varying the excitation. A "trip" governor should be used on all engines of this class to check racing in the event of a belt breaking or slipping off, a fuse blowing, or other similar accident.

Alternate-Current Measuring Instruments.

It has already been stated that the energy of an alternate-current circuit is proportional to the $\sqrt{\text{mean square}}$ value of the instantaneous values of the current, and it has also been stated that this $\sqrt{\text{mean square}}$ is equivalent to that of a continuous current that will produce the same heating effects. Therefore, alternate-current measuring instruments are calibrated by direct currents, and the readings on the scales are accordingly proportional to the $\sqrt{\text{mean square}}$ of either continuous or alternate currents. A few hints of a practical nature will assist engineers in selecting suitable instruments.

Precautions to be observed in Alternate-Current Working.

Owing to induction and capacity effects, it is usually necessary in alternate-current circuits to observe certain precautions in starting and stopping alternators, in opening and closing circuits, and in adding or withdrawing feeders from omnibus bars. It is proposed to suggest a few of the more common difficulties which may arise in practice. It must be recollected, however, that these effects are largely the result of the self-induction of the alternators, and that generally there will be no difficulty when the armatures have comparatively small reactions; as is the case with the Mordey Alternator, for example.

The chief danger to be apprehended is a sudden variation of pressure which may be sufficiently large to break down the insulation of the circuit at one or more points or to seriously affect the load. This is due both to the change of conversion ratio in the transformers and to the variations of impressed pressure in the alternators.

The precautions to be observed are:—

Never *open* a high-pressure circuit containing self-induction or capacity, without first slowing the alternator or weakening its excitation, or reduce the load by an impedance coil.

Never switch an alternator into parallel with another machine without first adjusting its excitation so that the *coupled* alternators will give the proper omnibus pressure.

Never switch an alternator out of parallel without adjusting its excitation (and that of the remaining machines if necessary) so as to leave the omnibus pressure unaffected.

An alternator of large self-induction requires to be excited to a higher pressure than that of the omnibus bars before coupling parallel as the terminal pressure will fall considerably when the circuit is closed. In taking such a machine out of parallel the excitation may be reduced until the current is nearly zero; or the speed may be lessened until the same end is attained. The switch under these conditions may be opened without a dangerous spark.

If, however, the conversion ratio of the transformers be effected by the capacity of the circuit (such as occurs with step-up transformers and concentric mains) then the incoming alternators with large self-induction must be under-excited in order to bring it into such a condition that it can be coupled to the active machines without affecting the pressure at the far end of the feeders; and conversely in taking it out of parallel, the excitation must be raised a little in order to avoid serious sparking on opening the circuit. These facts have been noticed in practice, and are explained by an alteration of the capacity and self-induction of the circuit affecting the conversion ratio of the transformer.

(To be continued.)

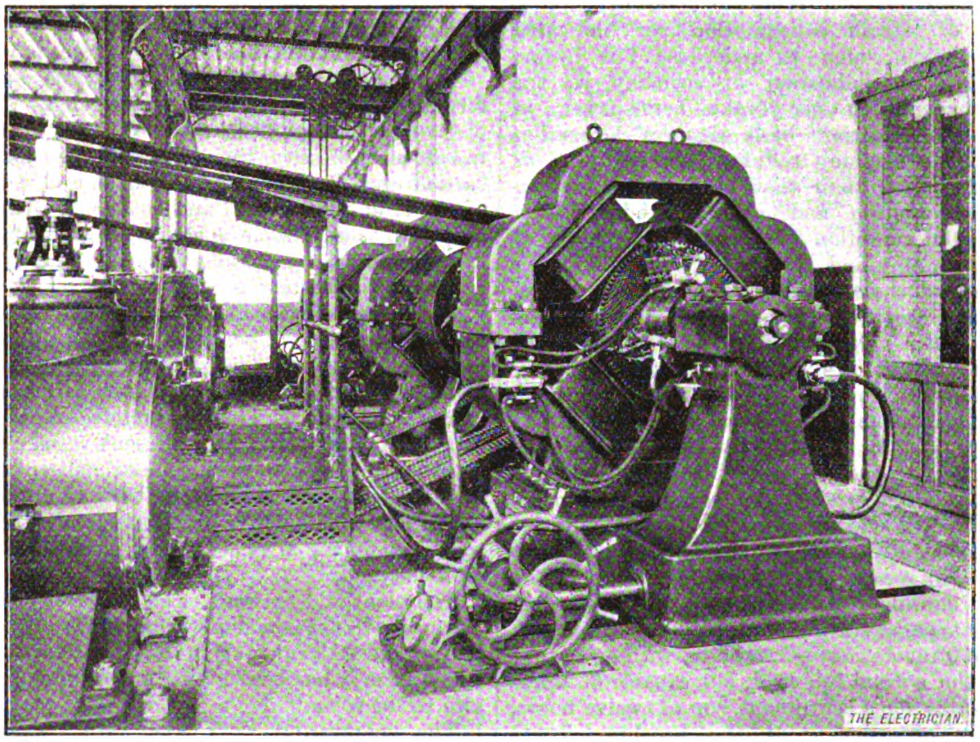
BRUSSELS CENTRAL ELECTRIC LIGHT STATION.

The electric lighting of the city of Brussels has been under the consideration of the Municipal Council for many years. The question of whether a concession should be granted to a company, or the enterprise be retained by the municipality in in its own hands, after having been much discussed, was eventually decided in favour of the latter alternative. Accordingly, in April, 1891, a general specification was drawn up and tenders were invited for a complete scheme of private and public lighting, the contractor selected to carry out the work being required to undertake the working of the station for two years, and to submit to heavy fines in the event of the actual working costs during this period exceeding their estimated costs.

Of the schemes submitted, including both alternating and continuous current plants, a three-wire low pressure distribution worked in conjunction with accumulators was selected; and on the 5th December, 1892, the India-Rubber, Gutta Percha and Telegraph Works Company, of Silvertown and Persan Beaumont, represented in Belgium by M. Boty, was entrusted with the execution of the contract, on the understanding that—as far as possible—all machinery, &c., should be constructed in Belgium. The site selected for the power station was that occupied by the old church of St. Catherine, Rue Melsens, in the lower part of the town, adjoining the main boulevard.

The station building includes a boiler and machine room on the ground floor, and on the first floor a battery room, repairing shop and stores over the machine room, whilst the coal store, water purifiers, and tanks are placed over the boiler room. The chimney is 190ft. high, and 8ft. 4in. internal diameter at the top. The coal store, of 200 tons capacity, being on the first floor; an electric lift has been constructed to convey the fuel to it. From the coal store the fuel is conveyed by suitable shoots to the stoke hold, these shoots being telescopic, so that they may be lowered to avoid the making of dust when coal is being discharged and raised out of the way at other times. The coal is hand-fed on to the grates. The water supply, both for condensation and feed, is obtained from the canal, which is distant about 350 yards, two 18in. pipes having been laid with a slight fall from the canal to a small reservoir under the machine room, to which are brought the suction pipes of the condenser pumps. A certain quantity of the condensing water, according to requirements, is pumped up to the water purifier, from which it is discharged into the main tanks. The water purifier, of the Dervaux type, is capable of dealing with about 2,500 gallons of water per hour, and the capacity of the main tanks, two in number, is about 22,500 gallons.

When complete the station will contain plant of 3,000 I.H.P., the unit adopted being a 500-H.P. engine driving two 250-H.P. dynamos. Provision is made for placing six such units, one being for reserve; but as the specification of the municipality stipulated that the machinery should be capable of working at 25 per cent. in excess of its normal full load, the ultimate maximum working capacity of the station may be taken as 3,000 H.P., not including reserve. The present boiler plant consists of three Babcock and Wilcox boilers, constructed by Brouhon of Liege, each of 2,440 square feet heating surface, and capable of evaporating 7,500lb. of water per hour with a good quality of Belgium coal. The boilers are of the usual type, working at 130lb. pressure, but with specially large grate surface (56 square feet) to allow of coke being used for firing, instead of coal. These boilers are fed by one Worthington pump, another being held in reserve, each pump capable of supplying to the boilers 2,600 gallons of water per hour. The feed water passes from the pumps through a Green's economiser, of which two have been provided, each of 2,160 square feet heating surface, and thence to the boilers. All the feed piping is in duplicate. All the steam piping is also in duplicate, two main pipes running across the tops of the boilers being carried through into the machine room, and running in a subway the whole length of it. Each boiler is connected to each of the two main pipes by a branch provided with a stop-valve; and a branch is taken from each main pipe to each engine.



Brussels Electric Light Station.—Engine Room; showing Dynamos, part of Engines, &c.

The machine room, which is 120ft. by 52ft. by 28ft., contains the engines, dynamos and switchboard, and is fitted with a traveller running its whole length, and capable of lifting 15 tons. To fulfil the stringent conditions as to the absence of vibration, a block of concrete, about 6ft. thick has been laid as a sub-foundation, which extends over the whole surface of the engine room, but is entirely independent of and isolated from the foundations of the building; and on this block the brickwork foundations for the engines and dynamos have been built; also separated from the walls of the building. The engines, two in number, are of Sulzer horizontal, side by side, compound condensing type, with adjustable cut-off supplied

by Carel frères of Ghent. The low-pressure cylinders are 40in. diameter, and the high-pressure cylinders 26in. diameter, the length of stroke being 4ft. The speed is capable of variation between 62 and 75 revolutions per minute, the higher speed being necessary for charging the accumulators. Each engine is fitted with two nine-grooved fly-wheels 20ft. in diameter, and weighing 20 tons. The most economical load for each machine is arranged at 400 H.P.; in order that over a range of 250 to 625 H.P. the consumption of steam per B.H.P. may be small, and a good efficiency be assured on the average working load throughout the year. For engines of a similar type, constructed by the same firm, tests carried on by the Association for the Supervision of Boilers, are said to have given the following results:—With an engine constructed for a normal output of 500 H.P. at 60 revolutions, when working at 138 H.P. with 84lb. pressure, the steam consumption on a test of eight hours was rather less than 13lb. steam per indicated horse-power-hour. With a similar type engine, 400 H.P. size, working at 85lb. pressure, and indicating 250 H.P., the steam consumption was 13·1lb. The same engine, tested $5\frac{1}{2}$ years later, had, it is said, a consumption of rather less than 14lb., working at 100lb. pressure and indicating 330 H.P.

With regard to these tests, it is to be observed—firstly, that the estimate of steam consumption per indicated horse-power in an engine which is under-loaded is by no means so satisfactory an indication of economy as the estimate of the consumption per brake horse-power, in any given time. The former basis ignores altogether the large proportion of engine friction, and merely shows an economy a little worse than that at full load, on account of extra condensation and other cylinder losses. When we take the consumption per brake horse-power at reduced loads we invariably find that it is very much higher than at full load, because the engine friction is practically constant. In the second place, it is to be observed that these tests tell us nothing about the performance of the engines at full load; and further, that the tests can only be properly appreciated when the details of the way in which they were taken are given. As they stand, the figures are so vastly superior to any practice in electric light engines with which we are acquainted, that we are quite unable to accept them on the mere statement of the Association to which reference has been made.

The engines are erected side by side with the cylinders at right angles to the length of the hall, and each engine drives two dynamos, by means of eighteen $1\frac{5}{8}$in. ropes. The dynamos, which are shown in the accompanying illustration, are of the four-pole type, shunt-wound with drum armature, running at 300 to 360 revolutions per minute, with an output of 145 kilowatts as the normal full load, but capable of working up to 180 kilowatts for a continuous run of twelve hours, without overheating or sparking at the brushes. These dynamos are carried on slide rails, to allow of the tightening of the rope drive as required, and are fitted with self-oiling bearings. They have been constructed, as also has the switchboard, by the Société Electricité et Hydraulique, to designs and plans supplied by the Silvertown Company. The switchboard, fitted for six pairs of dynamos, a battery of accumulators, and twenty-four feeders, is mounted on a gallery at a height of about 14ft. above the floor, so that the attendants have an uninterrupted view of all the machines. The general scheme of connection of the switchboard is as follows: each set of connections being the same for each pair of dynamos. The + pole of No. 1 dynamo is connected permanently to the − pole of dynamo No. 2, and both are connected by a cable, and a fusible cut-out to the neutral omnibus bar of the switchboard. The − pole of No. 1 dynamo is connected through a fusible cut-out and an ammeter to the fixed terminal of a two-way switch, by means of which the circuit can be made either on to the charging circuit of the accumulators, or on to the negative omnibus bar. The + pole of No. 2 dynamo is connected in the same way to the accumulators or positive omnibus bar. The exciting circuit of the dynamo is arranged as follows:—The + terminal of the shunt on dynamo No. 1, and the negative of No. 2 dynamo are permanently connected to the corresponding main dynamo terminals, and therefore to the neutral omnibus bar on the switchboard. The negative terminal of the shunt on dynamo No. 1 is connected to a switch fixed on the dynamo through which the circuit is connected to the negative omnibus bar, and adjustable resistance fixed on the switchboard being interposed to permit of variation in the exciting current. The + terminal of No. 2 dynamo is connected in the same way to the + omnibus bar on the switchboard. The shunt circuit switches on the dynamos are specially arranged to close the circuit of the shunt on that of an auxiliary resistance at the moment of rupture, to diminish the sparking and strains on the insulation.

For the main feeder circuits, 24 in number, each + feeder is connected through a separate adjustable main resistance and fusible cut-out with the + omnibus bar, the − feeder being connected in the same way to the − omnibus bar. The intermediate feeder is connected directly to the intermediate omnibus bar. To each distributing centre is led a three-core potential cable, 7/20 L.S.G., connected at one end to the three main cables in the distributing box at the "centre" and the other ends to a pair of voltmeters mounted on the switchboard, to indicate the pressure between the + feeder and the intermediate, as also between the − feeder and the intermediate. The pressure is kept constant on each side of the intermediate cable by varying the absorbing resistances in the main feeder circuits. The main resistance is of platinoid strip and fitted with contacts, to allow of separate adjustments of $\frac{1}{2}$ volt.

The accumulators, of the Julien type, are 140 in number, forming two batteries each of 70 cells. Each cell is capable of giving a normal discharge of 350 amperes for 10 hours, and in case of necessity the discharge may for a short time be carried up to 1,400 amperes without undue deterioration. The cases are of alloy of lead and antimony. The plates are widely separated, and ample space is left at the bottom for all material that may become detached during work. The total weight of the battery is 80 tons.

For the three-wire distribution each cable is drawn into a separate cast-iron pipe, with the exception of the potential cable, which is drawn into the same pipe as the intermediate cable. All the cables are continuously insulated, all joints being vulcanised. The conductors are of high-conductivity copper, 100 per cent. Matthiessen's standard, tinned and insulated with pure under-vulcanised indiarubber, taped overall, and the whole vulcanised together and strongly braided. The insulation resistance is 1,500 megohms per mile, tested in water at 60°F., after 24 hours' immersion and one minute's electrification.

The plant and network of mains having been duly examined and passed, the station was formally opened by the Burgermaster and Aldermen of Brussels on November 9, 1893, since which time it has been giving a continuous night and day service to the town.

The engineering work has been carried out under the superintendence of Mr. Stuart A. Russell, the contracting company's engineer; and the laying of the network and cables were carried out by Mr. Daubeny, the assistant engineer.

ON THE PROBABILITY OF IDENTITY BETWEEN SPECIFIC ELECTROSTATIC CAPACITY AND SPECIFIC ETHER DENSITY.

BY EDWIN J. HOUSTON AND A. E. KENNELLY.

The following simple consequence of Maxwell's electromagnetic theory of light may have escaped notice, or if noticed and already published, does not appear to have found its way into current literature.

Assuming that the magnetic permeability of ordinary transparent dielectrics is sensibly equal to that of the ether in free space, it was pointed out by Clerk Maxwell that as a necessary result of his electromagnetic theory of light, the specific electrostatic capacity of an isotropic dielectric medium should be equal to the square of its optical index of refraction for radiant energy waves of greatest length. This prediction is well-known to have been fairly well verified in quite a number of

transparent, solid, and liquid dielectrics, with notable exceptions in animal and vegetable oils.

But the index of refraction of a substance for a given wavelength is known to be the ratio of transmission velocity for such waves in free space to their transmission velocity within the body, and there is experimental evidence tending to show that it is the ether within a transparent substance which transmits light, and not the molecules of the substance itself.

The mechanism by which ether transmits radiant energy is not known, even though it be granted to be electromagnetic, especially since the exact nature of the ether is itself problematical, but Fizeau in 1859* first demonstrated experimentally that the velocity added to light traversing a moving transparent body was not the full component velocity of the body in the direction of luminous transmission, but a fraction thereof; namely, $(n^2-1)/n^2$, where n is the index of refraction. This experimental result was verified by Michelson and Morley in 1886.† The natural interpretation of this observation appears to be that the ether is denser within the substance of a body than in free space, and that this mean specific density must be the square of the index of refraction. Such a relation is in conformity also with the ordinary formulæ for the transmission of disturbance through material bodies; namely, $v \propto \sqrt{E/D}$.

If this indication of the Fizeau-Michelson-Morley experiments be admitted, it then follows that the numeric representing the specific electrostatic capacity of a body must be equal to the numeric representing the mean specific density of the ether in that body. Or in current notation, $v = 1/\sqrt{K\mu}$, and if $\mu = 1$, $n^2 = K$ and since $D = n^2 \therefore D = K$. If the ether possesses inertia, this deduction appears to favour the view that electrostatic displacement and stress are of kinetic nature, *i.e.*, that they involve motion, whirling, for example, of the ether particles. On the other hand, if the ether be devoid of inertia, the argument is, perhaps, reversed.

A further inference from Maxwell's verified theory and Fizeau's interpreted experiment is that crystals have different mean ether densities in different directions.

The following are a few specific ether densities according to the above view, and Klemencic's values:—

Air	1·000293
Hydrogen	1·000132
Carbonic acid	1·000492
Carbonic oxide	1·000347
Nitrous oxide	1·000579
Olefiant gas	1·000729
Marsh gas	1·000476
Carbonic disulphide	1·000450
Sulphurous acid	1·004770
Ether	1·003720
Ethyl chloride	1·007760
Ethyl bromide	1·007730

CORLISS COMPOUND ENGINES FOR ELECTRIC LIGHT WORK.‡

BY E. L. DEBELL.

The question of the utility of slow-speed Corliss engines for electric light work has been discussed at length among those interested in the subject, and a unanimous verdict has apparently not yet been arrived at. It is claimed by some that their motion is not steady enough for the work, while others believe they are suited for arc lighting, but not for the more sensitive incandescent lamp. Without attempting comparisons with other types, the writer will endeavour to give the conclusions arrived at from their use in the plant at Sheboygan, leaving such of you as are interested to compare them with results or knowledge obtained of the other types.

In our plant we have been running steadily for the past 15 months a Corliss cross compound, 24in. by 48in. high-pressure cylinder; two 46in. diameter low pressure; speed, 74 revolutions per minute; rated capacity about 650 h.p. We use a syphon condenser, supplied by a duplex pump with two 18in. steam and two 12in. water cylinders, 12in. stroke. We carry constantly 25in. of vacuum, which, however, can be readily increased to 28in. should the load be very heavy. When the load is light we consider it the best practice to keep it at 25in. and reduce the steam pressure.

A good Corliss engine of this size and type should handle its rated economical load on 18 pounds of water evaporated per horse-power-hour, and within a range of 20 per cent. above or below that point, or not over ½ pound additional. With good boilers properly fired and allowing 7½ pounds of water evaporated per pound of coal, this would equal 2 4-10 pounds of coal per horse-power-hour.

The first cost of the Corliss engine may be placed at one-third more than an equally well-made one of the high speed type, and it takes up about one-third more room. Its life, however, is generally conceded to be 50 per cent. longer, on account of larger wearing surface and slow speed.

The cost of attendance and oil and waste is practically the same as on any other good engine, while the cost of and the facility of making repairs seems to be in their favour. The latter feature is particularly true of the cross-compound, as the valves and valve gears can be readily overhauled in either cylinder without disturbing the other.

In the tandem compound, one cylinder being directly back of the other, the pistons and heads have to be removed from both to get at the cylinder next the engine frame. In an engine the size of ours it would be practically impossible to do this and make repairs between shutting down and starting time, which is a serious matter in plants depending upon one engine.

The cross-compound being connected to both ends of the shaft divides the wear between two sets of cranks, crossheads and bearings, while the tandem being connected to one end only the wear falls all on one set.

Another feature of the Corliss engine is that trouble usually develops slowly, in most cases giving warning of its existence in time to permit of the proper remedy before it becomes serious, sometimes saving a shut down of more or less duration.

The selection of proper sizes is a very important consideration, as the addition of an extra cylinder reduces the range of economy.

The load in nearly every electric light plant is so variable that one engine cannot do the work profitably, and it is probable that in most cases three engines of one size will give the best results. They should be large enough so that one will handle the light load, two of them the heavy load, leaving one always in reserve.

The cost of three engines will not be very much greater than the same capacity in one or two engines.

We are able to furnish a good light with our Corliss engine, and it is so regarded by our customers. At any time it is found otherwise the trouble is soon traced to some fault in operation and readily subdued. The conclusion we have arrived at is that these engines are well adapted for our work, economical in the use of fuel, durable and easy of repair.

‡ Abstract of a Paper read before the North-Western Electrical Association, Milwaukee, January 18, 1894.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, March 30th.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at the St. James' Hall Restaurant.

MONDAY, April 2nd.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture. "Photometry," by Capt. W. de W. Abney.

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

8 p.m. Smoking Concert at the Palatine Hotel, Hunt's Bank, Manchester.

TUESDAY, April 3rd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Electric Illumination," by Prof. J. A. Fleming.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Monthly Ballot. The following Paper will be read: "The Construction of Gas Works," by Charles Hunt.

WEDNESDAY, April 4th.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Conversazione at St. Martin's Town Hall.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. The following Paper will be read: "The Elements of Beauty in Ceramics," by C. F. Binns.

FRIDAY, April 6th.

ROYAL INSTITUTION.

9 p.m. Friday Evening Discourse. "Destructive Effects of Projectiles," by Prof. V. Horsley.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

COAL AND "COAL."

Ever since the old school of engineers began to reckon the "duty" of engines in foot pounds, per pound, hundred pounds, or per bushel of coal, it has been recognised that the quality of coal varies widely in different parts of the country. The voltmeter and ammeter afford to the engineer of to-day means for measuring the output of an engine with an accuracy undreamed of by the older engineers, who reckoned the work done by their pumping engines the diameter, length, and number of strokes and lift. While they used to speak of millions of foot pounds, simply because half a dozen cyphers had to appear in the value, some engineers of to-day run to an unnecessary number of decimal places simply because long division is so easy. The corrections which must be considered if the third figure, that is, the hundredths of a pound of coal per horse-power hour, or per Board of Trade unit, is to have any value, would probably entail more work than all the rest of a coal test. It is the custom, whenever coal consumption is recorded, to disparage the coal. "Stuff that they call coal," "slack," "duff," "smudge," or some other ill-favoured word is used; on rare occasions a chemical analysis with a merry row of decimal places gives tone to the test, but as a rule we are merely told that the calorific value is so much per cent. of the best Welsh coal.

The scientific method would be to state the duty of an engine in watt hours per unit of thermal value, thus eliminating the quality of the coal. A more practical way would be to assume a standard fuel, and this, for international comparisons, should be carbon. The use of the "carbon value" of a fuel was first suggested by Prof. UNWIN. Thus, one pound of best Welsh steam coal is equal to 1·104lb. of pure carbon; one pound of average British coal may be taken at 0·987lb. of carbon; an average sample of coke is only worth 0·934lb. of carbon, while an average sample of patent block fuel is worth

Digitized by Google

about 1·040lb. of carbon. Instead of quaint examples of local dialect, we should be simply informed that a kilowatt hour was obtained from the equivalent of so many pounds of carbon. To explain details of grate surface or stoking, the precise kind of rubbish may be described in suitably abusive terms.

In the first of two lectures delivered by Prof. A. B. W. Kennedy at the Finsbury Technical College in December last, the subject of boiler testing was considered from a thoroughly practical point of view. Many ridiculous reports have been made on tests of engines and boilers by engineers who, if ignorant of the principles as well as the numerous details which must be attended to in such work, were at the same time unconscious of their ignorance. We are glad to be able to give our readers a report of these lectures, and print the first one in our present issue. Tests of this kind consist in nothing more than scrupulous attention to carefully arranged details. No great skill or theoretical knowledge is necessary, and no expensive laboratory instruments and standards are required. The measure of efficiency of the plant of an electric supply station is for all practical purposes to be ascertained from the pounds of coal, or more accurately, the carbon value of the fuel, burned per supply unit sold. The relative cost of management is, of course, affected by the output of the station, but the fuel per unit has but little to do with the size of the station, though it depends on the conditions of working as shown by the load factor. Ample excuses have hitherto been found and granted for the greater coal consumption with alternate-current supply than with continuous currents; but now that the fixing of transformers in each house is admittedly old-fashioned, and the efficiencies of transformers have been greatly improved, it becomes the more important to discover where any waste of fuel may occur.

Useful work has been done by the Committee on Data, of the American National Electric Light Association, which has recently held its session in Washington. This committee exists for the purpose of collecting and comparing statistics of the cost of running electric power stations in the United States. It is particularly interesting to compare the figures given in its Report with the figures representing electric generating practice in this country. A list of 65 power stations, with the performance of each, accompanies the report; and it appears that an average of 91·7 watt-hours is obtained in these 67 stations for every pound of coal consumed. This is equivalent to 8·14lb. of coal per horse-power per hour, or nearly 11lb. per Board of Trade unit generated. The report further shows that where stations have been running continuously a very much higher coal duty has been obtained than where the loads on the stations have come irregularly. For example, in a station running the full 24 hours at fairly even load, 208 watt-hours per pound of hard screenings were obtained; while in a station doing an irregular service for 7 hours per day, only 85 watt-hours were obtained per pound of soft coal. The report also states that even in the best instances available the performance does "not compare favourably with the results secured in generating power for manufacturing purposes."

It is a pity that something more definite than the name of the class of coal used in each station could not have accompanied the report. A little, but nothing very exact, can be learned from such memoranda as "slack," "soft," "screenings," &c., which are tabulated under the head of "kind" of fuel. American coal is generally inferior to British coal, and it would be foolish to expect so high a duty from it. This will partly account for the large consumption of fuel per unit of energy generated, as compared with English results. On the other hand, in comparing American electric generating stations with American mills, all questions of fuel are eliminated. We may take it, then, that the American generating station engineer has a long pull and a strong pull to make before he can fully realise the best commercial duty of the fuel available to him. He seems to be troubled about small load-factors as much as we are.

THE TESTING OF ENGINES AND BOILERS.*

BY PROF. ALEX. B. W. KENNEDY, F.R.S.

Lecture I.—BOILER TESTING.

From the commercial point of view—that is, from the point of view of the engine or boiler user—the chief thing to be measured in connection with engines and boilers is naturally the ratio between the amount of coal used at one end of the scale and the amount of useful power obtained at the other end. Not forgetting that the working of engines and boilers entails expenditure in water, in lubricants, in stoves, &c., still the fact remains that fuel is the largest single source of expense which can be very certainly measured, and in which there is the greatest room for economy.

From our point of view we have to consider not merely coal and power—we must sub-divide the matter very much further. We must in the first place keep clearly separated the three matters: coal, steam, and power. We must, then, further remember that in each of these three sections a further subdivision must be made. In the case of the coal, for instance, we may have to distinguish between the total put on the fire and the total actually burnt, because really if all the coal that is put on the fire is not burnt, the remainder must be wasted. The steam, similarly, has to be divided into two parts, the total steam actually formed, and the portion of this steam which gets to the engines. Unfortunately it is quite possible to use steam pipes and valve chests and other parts of the engine as condensers only, and so to liquify a large part of your steam before it gets to the engines at all. Lastly, the power has to be subdivided into indicated power and useful power, because it is quite possible to have an engine which will waste as much in the difference between its indicated and its useful power, as may more than make up for any economical advantages for the use of steam, which it may have. I shall have something to say about each of these subdivisions, as we go on.

Looking now again at the three principal subdivisions we see at once that they give us to important ratios, viz., the steam per coal and the power per steam. The former is mearured as pounds of steam formed per pound of coal burnt, the latter is invested and measured as pounds of steam used per horse-power. The steam evaporated per pound of coal is the measure of the economy of your boiler alone. The steam used per horse-power is the measure of the economy of your engine alone. I have already pointed out that naturally the steam-owner may chiefly want to know the amount of coal used per horse-power, and this is the product of the other two ratios. Notwithstanding the practical importance of this, still for any purposes of testing, it is absolutely necessary to measure the two ratios separately, otherwise it is impossible to say whether any defect is due to the engines or to the boilers, or to say whether either by itself is working to the greatest advantage.

Perhaps no measurement of any kind is quite so simple as it appears at first sight, and to-night I am going to speak to you mainly about the first section of the work, that is to say, about the method of measuring the steam evaporated in a boiler by a certain weight of coal, in other words, about methods used for testing boilers. Now, although, of course, the great matter is to ascertain the weight of the water and coal accurately, this of itself is not sufficient, for two reasons. In the first place the coal is or may be of very varying quality, and it is no use for

* Two lectures delivered at the Finsbury Technical College, Dec., 1893.

the purpose of comparison to put together an evaporation by good South Welsh coal, and another by the sort of rubbish that you get in Scotland; it is necessary to have some standard of comparative value. Secondly, it is not sufficient merely to weigh the water going into the boiler, because, as you know, it requires much more heat to evaporate water to a high steam pressure than to a low one, so that we must have a standard for the value of steam.

Leaving this for the present, let us consider the standard for value of fuel. Several have been proposed, before examining them let me first remind you of the constitution of coal by writing down a typical analysis of a Welsh coal:—

Carbon	87·8 per cent.
Hydrogen	4·1 " "
Ash or incombustible matter	2·2 " "
Nitrogen, sulphur and oxygen	4·9 " "
Water (moisture)	1·0 " "
	100·0 per cent.

An analysis of this sort, of course, can only be determined by a chemist. Examination of it shows at once that coal consists of practically only two combustibles—carbon and hydrogen. The ash is not only no good to us, it is altogether undesirable. The water, of course, is absolutely no good. Of the other constituents, sulphur is the only one which has any thermal value. Our work is seldom so extremely accurate throughout as to justify us in taking the calorific value of the sulphur into account. Let us omit it, therefore, and take only the carbon and hydrogen into account:—

	Thermal units.
The thermal value of a pound of carbon is	14,500
That of a pound of hydrogen	52,500*

And the thermal values corresponding to the percentages of the combustibles in our sample are:—

	Thermal units.
Carbon	12,700
Hydrogen	2,130
Add these together and the thermal value of the coal is...	14,830

Now what have we got to compare this with? I need not spend time in telling you of all the proposed standards, and will simply say that the only one which appears to me really satisfactory is the thermal value of 1lb. of pure carbon. Measure the coal in terms of its "carbon value," a most useful expression, introduced, I believe, by Prof. Unwin. Treat the coal first as *dry coal*, deducting the water, much of which may be present merely accidentally. This would bring the value given above to 15,000 thermal units. The "carbon value" is then, of course, simply 15,000 divided by 14,500, which is = 1·034. In other words, the value of the coal is in this case 3·4 per cent. above that of pure carbon.

It may occur to you that it is rather a discouragement from the engineering point of view to suggest that at the very start we depend on the chemist. I fear I cannot help it! But note that there are three ways in which you can estimate the value of coal. The first and best is, of course, by having an analysis made, unless you can make it yourself. The second method is by the use of a calorimeter, that is to say, making a direct experiment on the thermal value of the fuel without analysing it. A calorimeter of a very practical kind is on the table, and Mr. Legros has kindly undertaken to explain it to you after my lecture. It is an apparatus in which a sample of coal can be burnt perfectly, and the heat which a definite weight gives out in combustion accurately measured. That will not, of course, tell you anything about the analysis, but it will give you the final figure (as 14,830 above) as the thermal value for the coal, and the apparatus is one which can be placed in the hands of an engineer. Or thirdly, very often you can find out from where the coal was got, what pit it came from, &c., and then find out from the numerous published analyses that of the particular coal in question.

Whether for analysis or for calorimetric determination you must make sure that you have a fair sample of your fuel. This is a thing which cannot be obtained without a little trouble. I

* This is the value of perfectly-burnt hydrogen, *exclusive* of the latent heat of the water formed in combustion, which passes away, of course, as vapour, not as liquid.

of the whole bulk of the fuel used. The whole quantity must afterwards be broken up and reduced to powder for final sampling.

Coal Measurement.—On one or two trials I have had the luxury of having the coals weighed beforehand into bags, each bag numbered and labelled ready for use. In 19 cases out of 20, however, you will have to weigh your coal as the trial proceeds. You should, therefore, have a weighing machine on the stoke-hole floor, or close to it. The coal is conveniently weighed in wheel-barrows, and the arm of the steelyard in the weighing machine should be set so as to correspond to an even weight of coal, plus the weight of the barrow itself. You should always weigh the coal itself to an even figure, and keep on weighing and tipping the coal down on to the stoke-hole floor as it is wanted. There is no rule for the amount that should be weighed at one time. It is often convenient to let it be such as will keep the stokers going for half-an-hour. I have, however, known cases in which there was nothing for it but simply keep on weighing continuously; in an ordinary boiler trial, however, there is no pressure of that kind. From 100lb. to 400lb. at a time, according to the size of the boiler, is generally the figure. Have a log sheet ready prepared, somehave on my own trials made it a rule that with every lot of 2cwt. or 3cwt. a handful is pitched on one side of the stokehole. Altogether these portions may amount to 40 or 50 pounds, and are fairly representative under ordinary conditions thing in the following form, for the purpose of marking down the coal as it is used.

Number of barrows.	Time started.	Time finished.	Total coal on fires.

I do not apologise for giving you such details as these headings, as it is most important for the log sheets to be thoroughly convenient. Let me point out one thing here, do not write down 10:5 in the time column; it is very apt to be misleading. Put 10:05. You must never have any mistake about your times. It is important to remember, as you will see at once on plotting a coal line, that the starting times and the finishing times form two completely separate series of observations. You may probably not finally use, or plot, both, but it is advisable to have both logged, as one is an excellent check on the other. One definite rule affects these observations, as all others, and it is simply this, that having once been started the observations must go straight on from beginning to end. Do not let the observer be flurried or bothered by anything extraneous to his work; let him simply write down at once any special circumstance that occurs, without in any way discontinuing the particular set of observations which he is making.

One question occurs at the start. How long are we going to go on? What shall be the duration of a boiler trial? As to this there is, of course, no absolute rule, but I should say that as a minimum, under very special circumstances, and in the hands of those who are very much accustomed to make boiler trials, you might get one in six hours, but that from eight to ten hours is the proper minimum. It is only after making a very great number of trials that you can shorten it. One occasionally hears of boiler trials which last two hours, or less. These are absolutely and entirely valueless, even when they are not simply frauds. No engineer who was at the same time both honest and experienced would ever put forward figures based on such trials. If you wish to get a really average boiler result, in such a case as that of an electric lighting station, a period of eight or ten hours is much too short, you will probably have to make the trial 24 hours or even 48.

Water Measurement.—There are three ways of doing this. You can, in the first place, measure water by meter, and on the wall I have shown the arrangement of meters which was used for measuring water on board the paddle-steamer "Ville de Douvres." It was a trial carried out by the Marine Engine Committee of the Institution of Mechanical Engineers. In this case we had duplicate meters and such an arrangement of pipes and valves as would enable us to run either meter in case of a breakdown of the other. Under ordinary

Digitized by Google

circumstances this is quite unnecessary. The meters used in this case were those of my namesake, Mr. Kennedy, of Kilmarnock, and are very satisfactory. But there are other meters—the Schönheyder meter, for example—which are well adapted for measuring large quantities of water. You cannot always get a water meter, however, and it is often a good deal of trouble to check it. There are then still two ways open to you. One very simple method is to weigh the water through a small tank placed upon a weighing machine, letting it run from this into a reservoir tank from which the feed pump takes its supply direct. The object of having this auxiliary tank is that your feed pumps may work continuously, otherwise you would have to stop while you were filling up the measuring tank. The method is a very good one, for the scale on which you weigh can easily be checked by standard weights. In some of the largest feed-water measurements which have been made, viz., for the engine trials of the Marine Engine Committee of the Institution of Mechanical Engineers, we used simply two measuring tanks, emptying and filling them alternately. At their sides were glass water gauges of their full depth. The top of each was made slightly conical, and carried an over-flow pipe 1½in. diameter open at the top. These tanks serve to measure enormous quantities of feed water. Nothing, of course, is directly weighed, the tanks are simply filled up alternately until they overflow at the top. If you use this method—the volumetric method—of measuring feed water, you must, of course, have previously checked the capacity of the tanks carefully by weighing water into them, at the right temperature, for which purpose it is convenient to use a standard ten-gallon can such as I have placed on the table.

The log sheets required for water measurements by the first method may be something like this:—

Time.	Number of weighed tanks finished.	Level in auxiliary tank.	Total water to boilers.

Of course, practically, you will keep the level in the auxiliary tank always the same. If you are going to use the double-tank method, you really want something like this:—

Right-hand tank. Number.	Time.	Left-hand tank. Number.

In a case of that kind, where you have to measure feed water continuously and "against time," you cannot have your log sheets too simple. You use simply numbers, and refer them to right and left hand, about which there can be no mistake. In the case of marine engines, such as those on the "Ville de Douvres," the water is going back to your boiler, surface condensed, and the level in the boiler ought to be constant except for the unavoidable loss of water. In ordinary land boilers the engine has no condenser, or if it has, it has not a surface condenser, and the water is therefore discharged to waste, so that the steadiness of the water level in your boilers depends on your stoker. As it is rather a nuisance to have to correct for the alterations of the water level, it is convenient to adopt the following methods: First, make the stoker keep the water a little too high, especially at the time when you have finished a tank. Stop the pump when the auxiliary tank is right, and then take for the time at which the measuring tank is finished the moment when you see that the water level has fallen to the proper point in the gauges.

This point must, of course, have been marked at the start, and it is not to be forgotten that the glass should be blown out before reading it. For marking the level, you can either tie a little bit of yarn round the glass so that the stoker can see it, or jam a piece of chalked wood between the nuts and make a good black mark on it. Do all you can to make the stoker keep his level as near right as possible continuously, and also to stoke as regularly as possible. You will then have the happy result that after the minimum time has passed, your trial cannot be wasted whatever happens. There is another thing to be done before the trial is started, namely, to go round and examine all the pipes, pumps and tanks and the boilers themselves, and to see that they are all tight, note all joints that are at all doubtful, and in any case where possible leakage might spoil your results, do not hesitate for a moment to use blank flanges. Look out for blow-off cock leaks. See that the boiler itself is not leaking anywhere, if you can possibly get at it. Make quite sure that the fittings and the feed pipes are not leaking. Of course, it is no use testing if the boiler is in bad order. During the trial do not let the safety valve blow off.

I think that after all these preliminaries we may now begin our trial. I remember there used to be a great deal of fuss made about the starting and finishing of a trial; it was thought to be necessary to draw all the fires and re-light them at the start, and then at the end to burn them down until they had practically gone out. This is unnecessary. Make sure that the boiler is at work two hours or more before the trial begins, the longer the better, so that everything may be hot and in normal working before you begin. After everything thus has been in full work for a time, then a little before you wish to begin (say, 10 or 15 minutes), stop stoking altogether. Clean up your stoke-hole floor and your ash pit. Necessarily your pressure will begin to drop. When it has dropped, say, 10lb., if you are working at 150, 5lb. if at 100, that is, when it has dropped so much that the fires cannot keep the work going any longer, mark the level on the water gauges, note the pressure, and commence the trial, calling this moment the time of start. (The full load must have been on the boiler all this time.) Note whether your feed pumps are on or off at the start—it is perhaps better that they should be off. As soon as the time of start has been definitely marked down, commence stoking your first lot of weighed coal.

When you come to the end of the trial do not try to finish at a particular instant fixed beforehand. Finish as you started, in this way:—Having made up your mind for a trial, say, of 10 hours, find out how long each weighed lot of coal lasts you, let us say half an hour. Then, when you have run for 9½ hours simply refrain from putting any more coal on the floor. Let the stokers make what they can of the last weighed lot. See that you keep the pressure as long as possible steady. Eventually, of course, it must go down, and the instant when it has fallen to the point at which you started is the real end of your trial, although, of course, except by chance, it will not be exactly 10 hours. By this means you have ensured that the fires at the end are as nearly as possible in the condition in which they were at the start. At the end of the trial the water level should also be the same as at the start, but sometimes it requires a little dodging with the pumps to get both the coal and the water measurements to finish exactly at the same time. In case it has proved impossible, as it sometimes does, to get a good start with your coal and a good start with your feed water at the same time, you can always get the average of each with sufficient accuracy from the plotted results, if your log sheets have been properly kept, and if your trial is of sufficient duration.

We may take it that we have now measured the total water and the total coal, and are able to standardise the latter. As to the standard for water you have simply to reduce the quantity that you have actually evaporated to the corresponding quantity, supposing the evaporation had taken place from and at 212°F. In general you will find that you have to multiply by 1·1 or 1·2 in order to bring the water to standard.

You have measured how much coal was actually put on the fires; how much has been actually burnt is got at by sampling the ashes and clinkers afterwards, and carefully finding out how much combustible there is left in them. It is quite possible that the waste material sent away as incombustible may be twice the weight of the ash, which would correspond to the original analysis of the coal. This, of course, means that you have wasted so much good burnable stuff, in addition to the real incombustible matter in the fuel.

Digitized by Google

The next question is, Did you evaporate all the water as steam, and not pass it away as water, because you must not credit your coal with evaporating anything which simply passed as water into the steam pipes? To find this out it is necessary to measure the priming, if there be any. There are two or three methods of doing this. In the United States, I believe, an apparatus is often used which is really a steam superheater, and the amount of wetness in the steam is determined by passing it through a narrow orifice, and measuring the rise of temperature above that of saturation. This method has several drawbacks. One is, that it is very difficult to measure accurately the increase in the temperature of the superheated steam. Another is, that extremely little is known of the properties of steam when only slightly superheated, and that the constants used in the determination have been calculated rather than found experimentally. But even if the method could be trusted it would not really give priming, but only *wetness*, which is quite another matter. Steam may be wet because of condensation in pipes, or other such causes, and yet there may have been no priming whatever. I have often found this to be the case, and the distinction is, of course, a very important one.

There is another and a very old method, which consists of blowing a certain quantity of the steam to be examined into a vessel of water, measuring its increase of weight and its increase of temperature, and calculating the wetness (for here again the priming proper is not determined) from these data. I have found this to be a most difficult and unsatisfactory method, and do not believe that under ordinary conditions it is possible to get anything by it beyond a general indication as to whether wetness is practically absent or is excessively large. The quantity looked for is so small, and the measurements are so liable to error, that the method is, in fact, quite useless.

The method which I have most often used myself (not that it is by any means perfect, but because it is the best I know of) is one for which the apparatus is on the table, and which will be shown by Mr. Burstall after the lecture. During the trial samples of steam are passed through a little surface condenser, and so collected as water, and taken away. An equal number of samples of water are taken out of the boiler at the same times as the steam samples. Use is made of the fact that chlorine can be detected in solution when present in very minute quantity by means of its reaction with silver nitrate solution in the presence of potassium chromate. The quantity of chlorine required is so small that in general it is unnecessary to add salt to the boiler water, but where this is extremely pure an addition of as much as 2lb. of salt per ton, or 0·1 per cent., is sufficient to enable the test to be carried out with an accuracy of within 0·5 per cent. in the determination of *priming*. If silver nitrate solution is added to a solution of any chloride in water, in the presence of potassium chromate, a white precipitate of silver chlorine is formed until no chlorine is left in solution. Immediately after the whole of the chlorine is precipitated silver chromate is formed, which is a deep red-coloured precipitate. The change of colour is very well marked, the addition of one drop of the solution of silver nitrate used being sufficient to produce a marked change of colour. As the addition of silver nitrate proceeds an indication of the degree of completeness of precipitation of the chloride is given by local reddish colouration, which disappears on shaking or stirring, some silver chromate being formed and decomposed on meeting the remaining chloride on mixing. If equal volumes of the steam and water samples are then treated with the silver nitrate solution the relative volumes of standard silver nitrate solution required to produce the red colouration will indicate the quantities of chlorine in the two samples, and therefore the amount of the boiler water which has been carried over as priming, so that if the boiler water required 100 c.c. of silver solution to produce the red colouration, and the same volume of condensed steam required 1 c.c. to produce it, then the quantities of chlorine present are as 100 to 1, and the priming is 1 per cent. It will be seen that the strength of the standard solution does not come into the results, the quantity of priming being read off on the scale of the burette used. The test is, as far as it goes, absolutely accurate, but it has two drawbacks: first, that it is very difficult to sample the steam, and, secondly, that it is not easy to sample the water. You can sample the steam by putting a little bent pipe (with its nose turned towards the steam) into the steam pipe, but you do not know that the steam obtained through this represents the average of the steam, and it is open to this objection. To sample the water in the boiler is also a little difficult, because you cannot say absolutely that the water taken from the gauge, and therefore near the surface in the boiler, fairly represents the average of that contained in the boiler, but it is most likely to be this water that is thrown up in priming. If you find 1 per cent. of priming by the test you can only say that it is about that amount, but if you find no salt present in the condensed steam you can say definitely that there is no priming, and this may be the case, although the steam at the engine is found to be very wet, owing to condensation in the steam pipe.

We may now assume that the total coal burnt and the total water evaporated have been measured, and further that by reducing both to standard we have been able to measure the thermal unit which the coal ought to have given up in its combustion, and the thermal unit which the water actually has taken up in its heating and evaporation. The ratio between the two quantities of heat is the "efficiency of the boiler," of which the value may be anywhere between 60 and (exceptionally) 80 per cent. There remains, therefore, a balance of 40 or 20 per cent. with which we have not as yet dealt. Clearly until we have found where this has gone the test cannot be considered complete. As to this, I can only in a few words point out where you have to look for it. First of all, most of it has gone up the chimney. For every pound of coal burnt you have probably sent 20 lbs. of gases up your chimney and away to waste. But this huge weight of material does not go up the chimney of its own accord. You must expend some energy to send it up, and this is the heat which carries it off. The exact determination of this quantity of heat is to a large extent a chemical matter. First, clearly you must find the weight of the gases. To do this you must sample them during the trial and then have them chemically analysed. When you have got their chemical composition, you can easily find the proportionate weight of the carbon in them. You already know the weight of the carbon which was put on the fire, and as this is the carbon which has gone up the chimney, it is only a matter of arithmetic to find from it the total weight of the gases. If for instance you have burn five tons of carbon, and you find, by analysis, that 4 per cent. of the total weight of the gases is carbon, then clearly the weight of the gases carried up the chimney is sensibly equal to $(\frac{100}{4} \times 5) = 125$ tons.* The rise of temperature of the chimney gases you can measure. It is not perhaps, quite easy, however, because it is very difficult to put your thermometer in such a place as to get the real average temperature of the chimney gases. Further, if that temperature be at all high, it is not easy to get a thermometer to measure it. An ordinary mercury thermometer would not do. I have used a thermometer in which there is compressed nitrogen over the mercury. You can measure temperatures up to 900°F. with such a thermometer, and at present I believe it is the best ordinary method available. No doubt, it will be superseded presently by thermo-electric methods. Let me caution you against one thing if you are measuring the furnace gases, take care of air leaks! Brickwork is very apt to prove anything but solid with a considerable difference of pressure on its two sides, and air holes and cracks only too often exist. This is a matter which has to be most carefully examined before you can at all make sure that the gases which you have got in your samples are not mixed with air that never went through the furnaces at all!

The second cause of waste is one that is clearly avoidable. It is that the carbon is not completely burnt to carbonic acid, but has partly passed away as carbonic oxide. This you can also only find out from a chemical analysis.

The third cause of waste is that you may not have burnt some of the coal at all, that your ash and clinker carry away a

* I have said here "sensibly equal," because in an exact calculation the question of the steam in the gases (formed by combustion of the hydrogen) must be considered. This matter would take me beyond the present limit altogether.

Digitized by Google

lot of combustible matter with him. This I have already mentioned. To find out how much this waste is you have to sample and analyse your ash, and find out how much combustible there is in it, again a chemical rather than an engineering process.

Lastly, there remains the continuous loss by radiation from the front of your boiler and all parts of its setting. I have made various attempts to measure this loss directly by finding the amount of coal which must be burnt in the boiler simply to keep the pressure up without any steam being made, but I must say, reluctantly, that the method is not a trustworthy one, and I do not know how to measure the radiation of a boiler. It may very often be a matter of 8, 10, or 12 per cent. As a matter of fact it comes in in the "heat account" really as a difference only, a quantity "unaccounted for," but necessary to make the heat expended tally with the heat taken away.

In my next lecture I shall have to speak of methods of testing *engines*.

ON CATHODE RAYS IN GASES UNDER ATMOSPHERIC PRESSURE AND IN EXTREME VACUA.*

BY PHILIPP LENARD.

(Continued from page 577.)

Cathode Rays in Vacuo.

12. When a discharge tube is exhausted to the highest degree the electric discharge is unable to pass through it. It is impossible to produce cathode rays in a perfect vacuum. It is, therefore, equally impossible to decide the question with an ordinary vacuum tube, whether the pressure of matter is necessary for the propagation of rays or not. But if we transfer the perfect vacuum from the discharge tube into the observing space, the corresponding experiment can be performed. Experiments to be detailed further on (18) showed that at moderate exhaustions in the observing space rays can be separated which increase in sharpness and length with decreasing pressure, and are affected by the magnet. For the highest vacua the apparatus was given the following form (Fig. 6):—

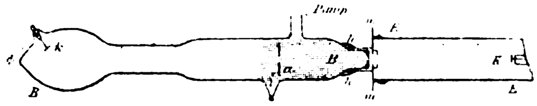

FIG. 6. (One quarter Size.)

To the windowed wall *m m* of the discharge tube E E (part only shown) is soldered the metal case *h h*, into which the glass tube B B, designed to enclose the observing space, is cemented. The tapered and cemented end of this tube is reduced to an aperture of 1·7mm., and over it is stuck the window (as usual, aluminium foil 0·0027mm. thick). The opening in *m m*, which before carried the window, is now free, and allows the rays to fall upon the window, while they are cut off by its cementation. This arrangement offers the advantage that the tube B B to be completely exhausted is not closed by any cementation except the inevitable fastening of the window. Into this observing tube are introduced the electrodes *a* and *k*. The electrode *a* is an aluminium disc, nearly filling the cross-section of the tube, and provided with a central hole 2·5mm. in diameter; it is also used as a diaphragm for cutting off some rays. The electrode *k* is a small disc of aluminium. The tube is joined to the same Geissler air-pump which also exhausts the discharge tube, but both spaces may be separately closed by cocks. The observing tube maintains the highest vacua unimpaired for hours, even when the discharge tube is filled with air. Hence the window must afford a perfectly tight joint. A case and screen are attached to the discharge tube as before.

If in the first instance the exhaustion in the observing space is about equal to that always maintained in the discharge tube, *i.e.*, equal to that used in Crooke's experiments, the following phenomena were observed. Between the window and the electrode, *a*, with the hole (now only acting as diaphragm), the whole glass wall glows bright green, while in the interior of the tube no light is perceptible. The green phosphorescent light of the glass also extends a little beyond the electrode, and penetrates a little into the tube leading to the pump, as shown in the figure by cross-hatching, and as required by a rectilinear propagation of cathode rays in all directions from the window. The window itself glows in the usual manner (3). From behind the electrode *a* up to the end of the tube the glass is dark except a pretty sharp patch Φ at the extreme end, about 9mm. across. Between the two electrodes *a* and *k* the air glows faintly blue.† If we bring a magnet near the observing tube, the distribution of the glass phosphorescence is altered, notably through the migration of the green patch Φ. If the south pole of a horse-shoe magnet is in front of the tube, and the north pole behind it, the patch is displaced downwards; on reversing the magnet it is displaced upwards. If the patch falls upon the electrode *k* it becomes invisible. The displacement of the patch is largest when the magnet is held between the diaphragm *a* and the window near the tube. The patch then approaches *a* pretty closely, and at the same time the glass phosphorescence is concentrated in front of the diaphragm more towards the side on which the patch falls.

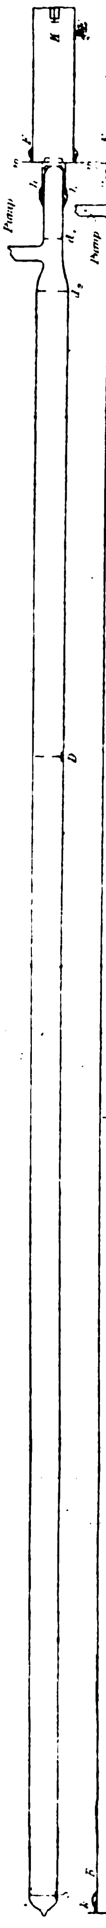

FIG. 7. (One quarter size.)

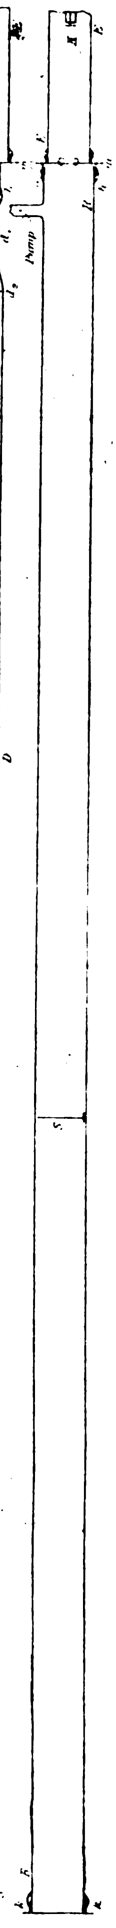

FIG. 9. (One quarter size.)

After the elimination of the greater portion of the turbid air, the rays have thus become nearly rectilinear, and have been propagated to much greater distances (30cm.) nearly without loss of intensity. Their behaviour in all cases, including that of the magnet, was quite the same as that characterising cathode rays in ordinary discharge tubes under equal exhaustions. Now, the chief interest of the experiment lies in the decision whether on further exhaustion of the observing space a reversal will take place, as it would if the discharge tube were further exhausted, viz., whether the glass phosphorescence will decrease in intensity and finally disappear. We disconnect, then, the discharge tube from the pump, and further exhaust the observing space alone. At the same time we connect the induction coil with the electrodes *a* and *k* of the observing space, to make sure that that exhaustion is reached at which reversal takes place. It takes several hours before the exhaustion is so far completed that the ringing impact of the mercury upon the cock of the air-pump indicates extreme exhaustion. At the same time the discharge between *a* and *k* becomes intermittent, the glass phosphorescence under the cathode *k* only flashes out now and then and in a few places, and shortly afterwards the discharge only takes place on the outside, in sparks running along the glass wall between *a* and *k*. The observing space is now exhausted so far that the reversal takes place, that it is impossible to *generate* cathode rays in it. If we now connect the induction coil in the usual manner with the discharge tube, we have the same phenomena as before in the observing space. Only the blue glow of the air between the electrodes is now absent; the interior of the observing space is now quite dark. The phosphorescence patch at the end of the tube can, therefore, be observed all the more easily. It is, perhaps, somewhat better defined than before, but not less bright. Between the diaphragm and the window the glass also glows very brightly. The deflection by the magnet is, in direction and estimated amount, the same as before. Granted the impossibility of *generating* cathode rays in this vacuum, yet that fact is no impediment to their *propagation*. The rays, also, do not introduce any perceptible amount of gas into the observing space; after the experiment the vacuum is entirely unaltered, the discharge between *a* and *k* failing, and the sound of the mercury in the pump being the same as before.

* *Wiedemann's Annalen.*

† As will be shown later on (17), this glow has no direct connection with the cathode rays.

Digitized by Google

13. In a yet more perfect and successful manner the same experiment was performed as follows:—The brightness of the glass phosphorescence just observed led me to expect rays a metre long. The glass tube enclosing the observing space was now made 1·5m. long, and 2·5cm. wide (Fig. 7). It was provided with a window, and joined to the discharge tube as before, only the window now had a double thickness (0·0045mm., instead of 0·0027mm., as before); it closed perfectly air-tight. The observing tube was without any ground joints or cocks blown on to a Tœpler-Hagen air-pump; the connecting tube was 1cm. wide. The Geissler pump now only served the discharge-tube. To exclude any disturbing reflection of the cathode rays at the somewhat long tapered end of the observing tube (near the window), two diaphragms of zinc, d_1 and d_2, with central openings 3mm. in diameter, were permanently fixed in the observing tube at distances 6cm. and 12cm. from the window. Thus only a small pencil of rays is produced, which proceeds along the axis of the tube, and only meets its walls near the end. From this pencil a movable zinc diaphragm, D, with an aperture of 2·1mm., picks out yet narrower rays, which are observed on the movable screen S as bright circular spots. The movable diaphragm is shown in Fig. 7*a*, natural size (perspectively); its base *e e* is a bent piece of sheet iron, which can be moved up and down in the tube at pleasure by means of a magnet. The phosphorescent screen* is similarly equipped.

After exhausting the observing space and freeing the glass walls by repeated heating from the larger portion of the condensed gases—an operation which took several days—the pump, in spite of intervals of a quarter of an hour between one stroke and the next, only showed gas bubbles which were too small to fill the section of the capillary into which they passed from the pump vessel. For some time further it was possible to urge these bubbles into the expansion of the capillary by various artifices, but after that the efficiency of the pump had reached its limit. But

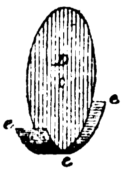

Fig. 7a. (Full Size.)

even this exhaustion, which was certainly higher than that attained in the previous experiment, offered no difficulty to the passage of the cathode rays. They were to be observed in remarkable purity, intensity, and definition. While the walls of the observing tube and its interior remained perfectly dark behind the first diaphragm, the phosphorescence patches on the screen were very bright and were in all positions of the diaphragm and he screen of the same size and definition, as might have been expected in the case of light radiated from a surface as large as the window. Only the strong deflection of the spots by the magnet indicated that the latter was not the case. As an example, we will give the diameters of the patches as found on the average when the diaphragm was placed at a distance of 50cm. from the window.

Table I.

Distance between screen and window.	Diameter of patch.	Calculated diameter.
Cm.	Mm.	Mm.
60	2·5	2·9
70	2·5	3·6
80	3·0	4·4
90	4·8	5·1
100	5·3	5·9
110	6·0	6·7
120	7·0	7·4
130	8·0	8·2
140	7·8	8·9
150	10·0	9·7

By the side of the observed diameters of the phosphorescence patches, in the third column, are placed the diameters as calculated under the assumption of rectilinear propagation, *i.e.*, the diameters of those circles to whose points straight lines lead from one point, at least, of the window surface (diameter, 1·7mm.) through the opening of the diaphragm (diameter, 2·1mm.).† It is seen that the observed patches are almost all a little smaller than the calculated ones, a circumstance which may be explained by the intensity decreasing gradually to zero at the margin of the patches, and which I have found to happen in the same manner in measuring patches of light. In a perfect vacuum, therefore, the propagation of cathode rays is not sensibly different from that of light.

It is to be noted that the patches did not always appear centrally on the screen, that often indeed they had to be brought on to the screen by the approach of a magnet. This is, however, not surprising, if we bear in mind that the iron supports of the diaphragm and screen acquired alternate permanent magnetism during use, as was shown by testing with a magnetic needle.

In this experiment also I tested whether the continued passage of cathode rays might be attended by increase of gas pressure in the observing space, but such an increase was not discovered. The volume of the small gas bubbles to which the 1,140 cubic cm. of the pumping vessel had contracted was estimated as before at 1 cubic mm., when a mercury column of 10mm. stood on these bubbles, communicating on the other side with the barometric vacuum. The gas pressure remaining in the observing space in this experiment comes out, therefore, as 0·000009mm. of mercury, or $0{\cdot}01 \times 10^{-6}$ atmosphere. The pressure of the mercury vapour from the pump at the temperature of the room would have been much larger (0·001mm.). But in this case the phosphoric acid tube between the observing space and the pump, together with a large empty sphere attached near the pump, was cooled down to − 21°C by a freezing mixture, so that the mercury vapour in the observing space could only have the pressure corresponding to this temperature, *i.e.*, 0·00002mm.*

14. We see, therefore, that cathode rays are also propagated in spaces which only contain matter in those states of extreme tenuity in which all its known effects vanish. Not to the traces of matter —whose more or less perfect removal was indeed without influence— but to the ether alone, which we are not able to banish from any space, must we therefore ascribe the causation of the intense effects

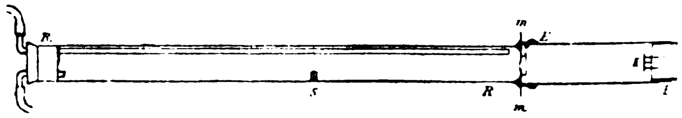

Fig. 8. (One quarter Size.)

observed. If this be granted, our experiment concerning the nature of the cathode rays will decide in favour of their being occurrences in the ether. This view is well known to have been adopted some time ago on other lines of reasoning by E. Wiedemann (*Wied. Ann.* 9, p. 159, 1880; 10, p. 251, 1880; 20, p. 781, 1883), and Hertz (*Wied. Ann.* 19, p. 816, 1883). It is also contained in Goldstein's views concerning the nature of electric discharges (*Wied. Ann.* 12, p. 264, 1881).

Cathode Rays in Various Gases.

15. The permeability of different gases for cathode rays is very different; it shows a connection with the densities of the gases. If coal-gas issues between the window and a phosphorescent screen, a perceptible brightening is noticed, best when the screen is already so far away from the window that it just remains dark in pure air. If the screen is to remain dark in the case of the coal-gas, it must be removed further from the window. The transparency of this gas, which is so opaque for infra-red and ultra-violet light, is truly surprising.

On filling the whole observing space with the gas to be tested, the results become purer, and the limiting distance of the screen from the window at which its luminosity just ceases gives a relative measure of the transparency of the gas investigated. For the performance of such experiments the glass tube R R, Fig. 8, 40 cm. long and 3cm. wide, is attached to the window wall, *m m*. At the other end it is closed by a stopper with two holes, through which are introduced a long and a short glass tube, as shown in the figure. The heavier gases are introduced through the lower and shorter, the lighter gases through the upper and longer tube, until they have completely displaced the air. From that time all gases enter by the long tube, so as to ensure having pure gas between window and screen. The screen S is again magnetically movable (13), Fig. 8*a* shows its natural size as seen from the window. On the window side it is completely covered with aluminium foil, so as to exclude all deception by light, especially the phoporescent light of the glass tube. Over the aluminium

* The ketone paper described in (4) can safely be employed, as special tests indicated—and this experiment confirms it—that the cathode rays separated from the electric discharge do not produce the usual decompositions accompanied by the evolution of gases.

† The diameters of those smaller circles, which are illuminated from all the points of the window surface would increase from 2·2mm. to 2·9mm. from the top to the bottom of the table.

* Calculated by Hertz's formula, *Wied. Ann.* 17, p. 198, 1882. Only after using the freezing mixture did the interior of the tube remain dark. This experiment was made in the summer; in the previous experiment (12) it was very cold, and the luminosity of the air disappeared, as stated, after simple exhaustion. The last trace of luminosity, or, as will be seen further on, the last trace of conductivity of the space, appears therefore to depend upon the presence of mercury vapours

Digitized by Google

lining is also laid a mica strip, *g g*. The screen is observed from the uncovered side, away from the window, and is alternately displaced and irradiated until the black shadow of the strip of mica, and hence the illumination of the screen altogether, has just vanished. This limiting position may be fixed with astonishing definition; by approaching it by 1mm. towards the window, traces of the mica shadow may be made to appear on the screen. This assumes, of course, that the cathode rays issuing from the window have constant initial intensity; that, in fact, the conditions of production are the same. Amongst the conditions of production special attention must be paid to the vacuum in the discharge-tube;* it was so adjusted that between the spheres, B (Fig. 1), now always placed 3cm. apart, sparks passed every now and then. This applies to all the following experiments, where nothing else is specified. The distances from the window of the screen in its limiting positions, read off on a strip of paper attached to the tube, are termed "radiation lengths" for the various gases (mean values).

Table II.

Gas.	Density.	Radiation length.
Hydrogen	1	29·5†
Nitrogen	14·0	6·5
Air	14·4	6·0
Oxygen	16·0	5·1
Carbonic acid	22·0	4·0
Sulphurous acid	32·0	2·3

The gases are arranged according to increasing densities. As is seen, this arrangement is also that according to increasing absorption. Large differences in density are attended by large differences in radiation length, and in accordance with the small differences between the densities of nitrogen, air, and oxygen we have only slight differences in radiation length. But that these differences do really exist I have proved to my satisfaction by repeated comparison of the three gases. Coal gas also ranged itself in the series, showing much longer rays than nitrogen, but not any lengths approaching hydrogen. Whether the air was free of dust, carbonic acid, or steam, or whether it was at rest or moving through the observing space, made no perceptible difference.

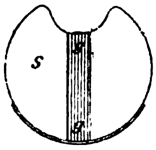

FIG. 8a. (Full Size.)

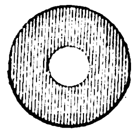

FIG. 9a. (Half Size.)

All the gases were illuminated by the cathode rays, like air (3). the light in this case is also limited to the vicinity of the window, and in hydrogen, for instance, does not extend anything like so far as the phosphorescence effect on the screen; in carbonic and sulphurous acids the light sheaf is very small, being larger in the less absorbing gases. Colour differences have not been observed in the various gases, but the apparatus is really little adapted to the purpose, owing to the bright phosphorescence of the glass walls. The much more visible luminosity of the window itself was always the same, in accordance with the explanation given above (4). The aluminium covering of the screen remained dark at all distances, and in all gases.

16. With increasing exhaustion the transparency of the gases increases; with great exhaustion the differences between the gases vanish. The transparency is again judged by the radiation length, but the observing space is arranged for exhaustion, and is made much longer and wider (Fig. 9). A glass tube 1·5m. long, 4·5 cm. wide, is cemented into a cup soldered to the window, and closed at the other end by a metal cap; a connecting tube leads to the Tœpler-Hagen pump. (The discharge tube is, as usual, connected with a Geissler pump). From this connecting tube another tube branches off, which terminates in a mercury valve (the lower part of a Bottomley‡ connecting piece), so that observing space and pump are closed against the air, and can also be connected with gas-generating apparatus without opening to the air. Everything closes tight enough to maintain the high vacua specified below. The phosphorescent screen, S, is constructed just as before; only its aluminium covering had now to be chosen especially thick, so that the observing space, 1·5m. in length, should be available for the higher exhaustions; this amounts to the use of a less highly phosphorescent screen. The covering consists of four aluminium films of 0·0133mm. total thickness (five times that of the window, 38 times that of aluminium foil). Across it is again fastened a strip casting a shadow.

As we exhaust the observing space through the various stages, find in each case the limiting position of the screen, and note its distance from the window as radiation length, we obtain for air and hydrogen the following table:—

Table III.

Air.		Hydrogen.	
Pressure.	Radiation length.	Pressure.	Radiation length.
mm.	cm.	mm.	cm.
760·0	2·35	760·0	10·6
331·0	4·53	335·0	21·1
165·0	8·38	167·0	32·4
83·7	12·1	88·0	38·8
40·5	17·1	42·2	56·1
19·3	27·2	20·3	74·9
10·0	49·5	10·3	96·8
2·7	73·0	3·3	122·0
0·78	107·0	0·65	125·0
0·074	127·0	0·065	126·0
0·019	140·0	0·030	131·0
0·0083	133·0	0·0164	130·0

It is seen, firstly, that the radiation length, and hence also the transparency, steadily and strongly increases with decreasing pressure; secondly, that it finally reaches the same limit in both gases. While the gas pressure is counted by millimetres of mercury the greater transparency of hydrogen is always strongly marked (approximately equal pressures are placed side by side in the table); but when the pressure has decreased to hundredths of a mm., the difference between the two gases has disappeared, and at the same time further exhaustion remains without influence. The differences of the radiation lengths contained in the last four lines of the table are not larger than their probable error, which I estimate at 5 per cent.* It is evident that the latter radiation lengths are no longer determined by the infinitesimal absorption due to the gaseous residuum, but the disappearance of the rays at the distances indicated is now only due to their rectilinear propagation in all directions from the window, according to which their intensity varies inversely as the square of the distance. In other gases it will be seen (18) that the transparency increases with diminishing pressure, whilst the differences between the various gases disappear.

How extraordinarily absorbent is air, and even hydrogen of ordinary pressure, will be gathered from a comparison of the lowest with the highest lines of the table: 130cm. radiation length in a vacuum, only 2cm. in air, and 10cm. in hydrogen. Quantitative conclusions derived from such observations will be more fitly reserved for a special communication to be devoted to absorption; but I might here introduce the observation forming the basis of such conclusions, viz., that the radiation lengths of the table are not perceptibly influenced by the presence of the glass walls of the observing space, that in fact they would not have been different if obtained in an open observing space. For two reasons the influence of the tube walls is thinkable. In the first place, the walls may, with a curvilinear propagation of the rays, make the screen appear darker than if they were absent, since they intercept a portion of the curvilinear paths between the window and the screen. Again, the walls might brighten the screen by reflection of the cathode rays. The first effect is only to be expected at higher pressures of gas (*see* 18); the second must, therefore, show itself in its greatest purity at the lowest pressures. To decide concerning the presence of an appreciable influence, a movable aluminium foil partition (Fig. 9a) was placed between the window and the screen, which, nearly touching the wall of the tube, left free a central hole 17mm. wide, *i.e.*, less than half the width of the tube. Let this partition at first be close to the window, where it must be quite ineffective, and let the screen be brought near its limiting position, where it only just distinctly shines out. If we now move the partition closer and closer to the screen we cut off more and more curvilinear paths from the window to the screen. Yet at first no distinct darkening of the latter is perceived. It is only when the partition has traversed more than half the way towards the screen, *i.e.*, when it also begins to cut off rectilinear paths, that it darkens the edge of the screen. The experiment was performed with equal success in air of 117, 15, 2·8 and 0·035mm. pressure.

* The E.M.F. of the accumulators feeding the induction coil was very constant, and was tested at regular intervals by means of a glow lamp.

† In my first communication, *Berl. Ber.* 1893, p. 7, this length is given as only 20cm. I had then not yet paid much attention to constant initial intensity. Under the precautions adopted, I have never, even in repeated experiments with constantly renewed hydrogen charges, obtained such a short radiation length.

‡ Bottomley. *Proc.* Roy. Soc., 40, p. 249, 1886.

* This comparatively great uncertainty is not attached to the limiting position of the screen, but is due to slight periodic variations of the initial intensity of the cathode rays connected with the state of the mercury interruptor.

Digitized by Google

At the three higher pressures the darkening of the screen edge was blurred, at the lowest the partition cast a nearly sharp, circular shadow. This experiment shows, at the higher pressures, that curvilinear rays (although actually present) have no perceptible effect upon the screen in its limiting position. At the lowest pressure, where the rays are already rectilinear, the experiment shows that reflected rays are likewise imperceptible. For when the partition is midway between window and screen it casts into shadow the portion of the tube wall lying behind it up to the screen (as may also be seen by the absence of the glass phosphorescence), so that this portion cannot reflect at all. At the same time it prevents all rays reflected from the unobscured portion of the tube nearer the window from reaching the middle of the screen; yet this centre does not appear obscured; it is only the edge which shows the shadow of the partition. The assumption above enunciated is therefore proved (compare also the experiment (4) with the glass and tinfoil tube).

(To be concluded.)

LEGAL INTELLIGENCE.

Wise v. Metropolitan Electric Supply Company.

This action, which relates to alleged vibration caused by the Manchester-square Station electric-lighting plant, came on for hearing before Mr. Justice Stirling on Tuesday, March 13th. Mr. Graham Hastings, Q.C., and Mr. Beaumont appeared for the plaintiffs, and Sir Richard Webster, Q.C., Mr. Phipson Beale, Q.C., and Mr. Vernon Smith for the defendants. Mr. Graham Hastings opened the case for the plaintiffs, and called witnesses in support of his statements.

Prof. SILVANUS THOMPSON, examined by Mr. Graham Hastings, stated he attended at Mr. Wise's house, 43, Manchester-street, on November 16th last, Prof. Kennedy and Mr. Bailey, the defendants' engineer, being present at the time. There were ten machines in the station. No. 1 was still, and No. 10 was running light. The others were running and supplying current. The vibration at the house on that occasion was not nearly so strong as he felt it in the same house on subsequent occasions. Slight intermittent tremors were observable at Nos. 44 and 45. The time was about 6:45 p.m. They then crossed the road to No. 8, where he noticed a "howling" noise from the alternators. At No. 9, getting on for eight o'clock, there was a tremor which could be felt by leaning against the wooden partition. There was also a hum. His next visit was on December 14th, about six o'clock. He went to No. 43 first. In the second-floor sitting-room there was a perceptible tremor and an occasional rattle. Down to the basement there was nothing perceptible. In the back he noticed nothing; in the front nothing perceptible. In the cellar reaching out under the street the noise of the alternators was distinctly perceptible. Then he went across to No. 17, Mr. Grant's house, about 6:50 to 7. In the ground-floor front sitting-room there was a tremor perceptible; in the bed-room behind, the window rattled, though it was wedged up, and the "screaming" of the machines was perceptible in another building built out further behind the house. The next visit to No. 43 was on the 26th; the vibration felt on floor, table, and chairs of second floor front was most unpleasant. He went across to No. 17 at 5:37. The windows were rammed up with wooden wedges, so that the occupants could not open them. His next visit was on December 27th, it was earlier in the afternoon, at a quarter past 3; it was was a grey day, but it was daylight. He went to 43, Manchester-street. The second-floor front room was quieter than on any previous occasion, but tremors were perceptible in the floor and the table, and there was a slight rattle on the small side-board between the windows. In the third-floor front bed-roqm there was a slight rattle in the window, but the back bed-room was quiet. On the first-floor front room, the drawing-room, there was a tremor in the floor, faint, but quite perceptible. On the ground-floor front room, the dining-room, the window chattered incessantly, though fastened and tightly wedged. He then went across to No. 8, and he found faint tremors all over the house. He then went to No. 9. Similar visits with similar results were paid on December 23th, January 11th, and February 21st. On March 1st he inspected the Works to see what had been done in the way of alterations to the bed plates of the machinery, and the trench that had been cut. Before going to the Works he visited two of the houses, Nos. 43 and 17, and after the inspection he went back to them. Mr. Wise stated that the vibration was strong till 5 p.m. His next visit was on March 6th, to No. 17, at 4:34; to No. 43, Mr. Wise's, at 4:40; there was a perceptible vibration, but less than on any other previous occasion. He again visited the houses the same evening about 11:30. He went again the next day, March 7th, at five o'clock to No. 43, vibration was perceptible. He then went to No. 44, Mr. Leighfield's, and in the first-floor front room he found all the floor vibrating gently, the centre part strongly, the leaf of the palm-tree vibrating incessantly with an amplitude varying from an eighth of an inch to half an inch. He went down into the basement and crossed in the basement into No. 45. In the back basement, which had a stone floor, there was a sink inset in the back wall at a part where it appeared to be about 21in. thick. Standing on this sink was a small tub and the water in the tub showed a regular periodic ripple. The front basement of No. 44 was used as a parlour, he found the window rattling with intermittances of about nine seconds. He went across to No. 9; on the ground-floor front the floor was in vibration, which he found unpleasant when sitting in an armchair. On Friday, March 9th, he made some experiments with a phonograph. He had a little apparatus made, to enable him to distinguish as far as possible between any casual vibration due to motions in the house, and the kind of vibration that was set up by machinery, the continuous tremor. There was a pane of glass in a frame with a marble bullet held close to it on the end of thin wire. The little bullet could be set at various heights. One put this apparatus down in a house that was shaking and adjusted the stem until one found the position that responded best to the vibrations in the house. Then the little ball rattled against the pane of glass as long as there was regular vibration. As soon as the vibration died away the knocking of the bullet against the glass died away also, and a cab or even a heavy cart passing in the street could not produce any effect at all, because it required the repeated impulses coming one after the other to set the bullet in motion. He (the witness) then procured a phonograph to record the sounds. The records were in Court, so that his Lordship could listen to the tapping as recorded in the house. He made two records on the night of March 9th. One was in No. 46, the pane of glass being set up on the top of an iron safe standing in one corner of a room close to the wall. [His Lordship then listened to the phonograph records.] When he first went to the Manchester-square station on November 16th alterations were in progress. The bed plates originally stood on brick piers 12ft. high. They had now put them on iron cylinders intended to go 40ft. into the ground. He doubted whether what they had done would remove the noises and vibrations. In the first place, because the perpendicular cylinders passed through intermediate layers of sand, clay, gravel, and so forth, and unless they were isolated from the surrounding soil their vibration would certainly be communicated to the surrounding soil. In the second place, because, having regard to the very uncertain nature of the bottom there, he thought it extremely doubtful whether they had really got all the pillars footed on the same stratum. The fact that one could hear the actual sound of the station through the soil of the roadway showed that the soil admirably carried vibration.

Cross-examined by Mr. Phipson Beale, WITNESS stated he found differences not only in the same houses at different times, but between the different houses at the same time. He could not explain why in two houses, side by side, in two corresponding rooms he found the effect different. Something might be due, of course, to the structural defects of the house itself. He attributed the fact that a room that was comfortably quiet on one day was vibrating unpleasantly on another to some difference at the station. His impression was that upon his first visit to station the vertical columns at the station had all been put in. Witness had heard of alternators which made less noise than those at Manchester-square, though any alternator would probably make some noise. He thought the site of the station was unsuitable. They were not bound to put the station in the area at all.

The Rev. GEORGE WILLIAM SANFORD, examined by Mr. Beaumont, stated that he had from time to time stayed at either 8 or 9, Manchester-street (Mr. Gillam's houses) during the last ten years. He last stayed there in April, 1893, from the 11th to the 20th. He had had no reason to complain of the rooms before that time, but then the vibration was very serious. It varied considerably, but was practically always slightly perceptible. He had hitherto recommended Mr. Gillam's rooms, but would not feel at liberty to do so now without mentioning the vibration and noise.

Cross-examined by Mr. Phipson Beale, WITNESS said that he stayed at Mr. Gillam's before April of last year—in the spring of 1892—when the electric works were going. The annoyance then was nothing to complain of.

Mr. MACKENZIE, examined by Mr. Graham Hastings, said that he had stayed in Mr. Gillam's second floor, No. 8, for five years, from October, 1888, till October 29, 1893, when he left on account of the vibration, which he had noticed in the previous April had seriously increased.

Miss FLORENCE MARIAN COLLIER, examined by Mr. Graham Hastings, stated that she and her sister had stayed in one of Mr. Gillam's houses in Manchester-street from time to time during the last four years, very often for six or seven months at a time. She had had no reason to complain of the rooms except from the vibration. She was there in April, 1893, and found it very bad. She returned in October, November, and December; it was much worse still when she returned in October. It was almost like being on the sea.

Cross-examined by Mr. Phipson Beale, WITNESS stated she had stayed at Mr. Gillam's from October, 1893, till February last, with the exception of two or three weeks at Christmas.

Mr. REGINALD BRUCE FELLOWES, examined by Mr. Beaumont, gave evidence to the effect that the noise and vibration proved very tiresome when he tried to work. He left Mr. Gillam's in February.

Mr. FREDERICK HENRY THORNE and Mr. ERNEST WILLIAM ESSELL gave similar testimony.

Mr. FREDERICK WILLIAM HUNT, examined by Mr. Graham Hastings, stated that he was the agent for Lord Portman's Marylebone estate. The lessee of the site upon which the Manchester-square Station stood was a Mr. White. Witness objected to his transferring the agreement to the Electric Light Company. But he (witness) had every assurance from the Company's representatives that they were confident there would be no annoyance. Finally, the lease was taken over subject to all the covenants being observed. In 1891 the tenants began to distinctly complain, and had continued to do so up to the present time. On December 23, 1892, a meeting of petitioners took place at the Portman office. The secretary of the Company was present. Mr. Owen said the Company were making inquiries and asking advice as to what they should do to stop the annoyance. The annoyance was not denied. The plaintiffs' houses were very fairly substantial houses, and were put in very good repair by all the tenants from 1885 to 1888.

Cross-examined by Mr. Phipson Beale, WITNESS stated that the Vestry Clerk asked him if he could help him as to a site for electric light works. He (witness) was very glad that all the tenants should have the electric light. He did not recollect saying that in his opinion the present site was the most suitable of any place between Oxford-street and the

Digitized by Google

Marylebone-road. He had never looked upon the site as being unsuitable for buildings requiring good foundations by reason of the Tyburn Brook, or anything of that kind.

Mr. MILES WALKER, examined by Mr. Beaumont, said he was assistant to Prof. Silvanus Thompson and agreed with his evidence.

Col. JAMES FREDERICK PEARSON, examined by Mr. Graham Hastings, stated that he resided at Eastbourne, and on coming to London had on several occasions taken rooms at Mr. Wise's house at 43, Manchester-street. He recollected staying there in January, 1889, for about three weeks, and on subsequent occasions. He first noticed vibration in November or December, 1892. He considered the vibration an intolerable nuisance.

Mr. JAMES WISE was examined by Mr. Beaumont, and stated that he first began to notice the vibration caused by the works in March, 1891. In the autumn of 1892 it began to be felt very strongly in the two upper floors. He did not make complaints till about the end of October or November. On November, 17, 1892, he and his neighbour went to the Manchester-square Station, and spoke to an official of the Company. An official there and then came over to his house, and admitted the vibrations. On November 21st, and on subsequent occasions, Mr. Bailey came and inspected his house. The nuisance had quite upset his nervous system, and he had had to consult Dr. Broadbent and also Dr. Jackson of Manchester-square. He had lost customers through the vibration. His receipts had fallen off considerably since September, 1892. He attributed this partly to the nuisance and partly to the bad times.

Cross-examined by Sir Richard Webster, WITNESS denied that he had told Mr. Bailey, or anyone else connected with the Company, that the vibration had been better during the last part of 1893. What he had said was that it affected his house differently from other houses, because it had been more felt through his house; but other years it had been confined to his two upper floors.

Mr. WILLIAM HENRY GRANT, examined by Mr. Graham Hastings, stated that he had been in 17, Manchester-street, since April, 1886. He first noticed vibration in June, 1890, and received complaints on the subject from lodgers in that year and in that month, and since.

Cross-examined by Sir Richard Webster, WITNESS stated that although the vibration was the main cause of complaint, the smuts would in time have become a nuisance.

Mr. F. G. Leighfield, Mr. W. Gillam, Mr. W. Barrell, Mr. W. Hales, and Mr. Frank Hudson Leighfield were then examined and gave evidence to the same effect as the other plaintiffs. Sir Richard Webster then opened the case for the defendants, and the Court adjourned over the Vacation.

Selfer and Meux's Brewery Company v. the City of London Electric Lighting Company (Limited).

These two actions, which came before Mr. Justice Kekewich last week, are by the tenant of the Waterman's Arms, Bankside, Southwark, and his landlords, and arise out of alleged detrimental vibration from the defendant Company's works. Counsel, representing all parties, asked that a day should be named for the trial, and for instructions as to their procedure. After some conversation, his Lordship said his experience was that affidavits, of which it seemed a considerable number had been filed, were of very little use in arriving at a conclusion in a case of this kind, and there would have to be a proper trial with witnesses. This was assented to on both sides.

CORRESPONDENCE.

TESTING IRON OF TRANSFORMERS BY A WORKSHOP METHOD.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your number of March 23rd there is a misprint in the formula regarding the eddy-current loss per cubic centimetre for iron wires. Of course, this loss is smaller than that in iron sheets of equal thickness b (in mms.) The formulæ should be :—

for sheets, $$\left(\frac{b \cdot p \cdot \mathbf{B}_{max}}{2{\cdot}5 \times 10^6}\right)^2 \text{ watts,}$$

and for wires, $$\left(\frac{b \cdot p \cdot \mathbf{B}_{max}}{4 \times 10^6}\right)^2 \text{ watts.}$$

The values of the tables on *p.* 582 are calculated from these formulæ.

You would oblige me by publishing this correction in your esteemed journal.—Yours, &c.,

CLARENCE P. FELDMANN.

Cologne, March 27, 1894.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Directors of the Lancashire and Yorkshire Railway Company are prepared to receive tenders for the supply of a quantity of stores for the twelve months ending April 30, 1895. Some particulars are given in our advertisement columns, and further information and forms of tender can be had on application to the Stores Department, Osborne-street, Manchester. Tenders must be lodged with Mr. C. W. Bayley, the secretary, not later than 10 a.m. on Monday, April 9th.

TENDERS ACCEPTED.—The Vestry of St. Pancras has accepted the tender of Messrs. Crompton and Co. for the supply of engines and dynamos required for the new station at King's-road, for the sum of £6,917. 9s.

———— The School Board for Hanley have received the following tenders for lighting the Higher Grade Schools by electricity (Mr. E. Scrivener, Hanley, architect) :—

	£	s.	d.
B. Verity and Sons, Manchester Branch (accepted) ..	£398	11	6
Spagnoletti and Crookes, London	436	17	0
J. Blackburn, Nottingham	466	14	8
Maunsell Mercier and Co., Manchester	475	10	0
Fowler, Lancaster and Co., Birmingham	557	13	0
Laing, Wharton and Down, London	586	8	9
Brush Electrical Engineering Company, London	588	19	9
Ball and Co., Bristol	661	7	3

SALES BY AUCTION.—Messrs. G. A. Wilkinson and Sons announce the sale by auction at the Mart, Tokenhouse-yard, London, E.C., on Monday, April 23rd, at 2 o'clock, of the important freehold property, situated at Hammersmith-road, West Kensington, lately in the occupation of Messrs. Woodhouse and Rawson United (Limited). The premises comprise three large factories, engine and boiler houses, offices, stabling, &c., portions of which are let off at rentals amounting to £525 per annum. Further particulars are given in our advertisement columns, and all information can be obtained of Messrs. Langbourne, Stevens and Powell, 7, Lincoln's Inn-fields, W.C.; Messrs. Maddisons, 1, King's Arms-yard, E.C.; Messrs. Robinson and Leslie, 74, Coleman-street, E.C.; or the Auctioneers, 7, Poultry, E.C.

———— Messrs. Fuller, Horsey, Sons, and Cassell will sell by auction at the Dockyard, Chatham, on Monday, April 2nd, and following days, at 12 o'clock, a quantity of old and surplus stores, including six tons of india-rubber, 500 tons wire rope, 35 tons rivets, 50 tons brass, 19,550 yards electric cable, &c., &c. Catalogues can be obtained at the Dockyard, and of the Auctioneer, 11, Billiter-square, E.C.

APPOINTMENTS VACANT.—The Salt Lake and Ogden Gas and Electric Light Company (Limited) require a general manager at their works at Salt Lake City, Utah. A liberal salary is promised to a first-class man. Applications must be made by letter, to Mr. J. A. Kelman, secretary, Winchester House, London, E.C.

———— A clerk of the works to superintend the laying of the cables and fitting up of the central station equipment is required by the Corporation of the Borough of Southport. Applications must be sent in to Mr. J. Davies Williams, Town Clerk, Town Hall, Southport, not later than April 9th. Some further particulars are given in our advertisement columns.

LIQUIDATIONS.—The creditors and shareholders of Newington, Priddle and Co. (Limited) met before Mr. Warley, assistant receiver, on Thursday. Mr. Warley reported that the whole of the property and goodwill of the business had been sold for £330, and with the exception of the collection of the book debts, there was little more to be done under the liquidation proceedings. The case was left in the hands of the Official Receiver to be wound up in the usual manner.

———— A meeting of the members of the Orient Electric Lighting Company (Limited) will be held at 43, Finsbury-square, E.C., on April 21st, at 11 a.m., to receive the liquidator's account of the winding up.

———— Claims against Blakey, Emmott and Co., Limited (in voluntary liquidation), must be sent in to the liquidator, Mr. James Lakeman, 30 and 31, St. Swithin's-lane, London, E.C., by April 7th.

REMOVAL.—On and after May 1st the executive offices in New York of the Commercial Cable Company will be permanently located in the new Postal Telegraph Building, a huge block situate at the corner of Murray-street, 253, Broadway, where will also be located the executive offices and main operating department of the Postal Telegraph-Cable Company.

PERSONAL.—The Corporation of Kingston-upon-Thames have increased the salary of the Borough Electrical Engineer (Mr. J. E. Edgcome) to £250 a year, and have appointed him advising

Digitized by Google

engineer to the Drainage Committee with regard to the machinery at the sewage works.

Mr. K. Schall.—We are in receipt of an illustrated price list giving particulars of new and second-hand batteries and instruments for sale by this firm.

Messrs. Baxendale and Co.—This firm's electrical department have recently obtained contracts for lighting the Bromley-street Mills, at Manchester, for which a complete plant is to be supplied. Included in a number of other contracts recently secured are the wiring of the Wesleyan Chapel, at Nelson, and of Messrs. W. Thompson and Co.'s two establishments at Spring-gardens, Manchester. The list of recent installations carried out by the firm number about seventy.

The Forty-Eight Hours' Week.—Mr. W. Mather, M.P., has just published a report of a year's trial given by Messrs. Mather and Platt (Limited), at their works at Manchester, of the forty-eight hours' week. After stating that the full complement of men employed at Salford is 1,200, subject, of course, to the various exigencies of business, Mr. Mather points out that during the period of trial no overtime was worked except for breakdowns and repairs. In the course of the report very full support is given to the advantages claimed for the eight-hours' system. The report concludes:—"Our year's trial has convinced us that we have found the happy medium in the number of hours during which only one meal and one stoppage are needed, and this resolves itself in the eight hours day or forty-eight hours' week."

Mining Plant.—The *South African Mining Journal* contains an account of the new electrical plant recently installed at the Crown Reef Mines. Electric pumping is being carried on and the electric light is in full working order. Electric locomotives have been run experimentally, with very satisfactory results; and Mr. Hubert Davies, who has designed and erected the plant, is congratulated on all sides. There are three 90-unit shunt-wound Elwell-Parker generators for power purposes and two alternators and two exciters for lighting. In the lighting eight 2,000-c.p. arcs are used, and 28 200-c.p. and 500 16-c.p. incandescents. Two sets of electric pumps are ultimately to be fixed at the dam pumping station to supply water to the mill. One of the pumps is already at work capable of supplying 60,000 gallons per hour through more than 3,000ft. of piping, under a vertical head of about 250ft. Trial runs have been made over the electric tramway, which is worked on the overhead system. The total weight of the locomotives (of which there are two) is about 10,000lb., and which will be capable of moving about 25 empty trucks from the mill to the mine at one run. This is the first instance in which electrical haulage has been adopted on the Rand, and is on a large scale.

"Willing's British and Irish PressGuide."—The new edition of this very handy list of newspapers and publications is just issued. Those likely to require the names of books or journals which are regularly published throughout the country will find them here set out in a very handy way. There is one complete alphabetical section in which everything, either daily, weekly, monthly, or quarterly, is combined, rendering the task of finding any particular publication a simple one. So far as we have tested the list, it is quite up to date.

Launch.—A new passenger steamer was launched last week from the shipbuilding yard of Messrs. W. B. Thompson and Co., of Dundee, named the "Fingal." The electric light has been adopted throughout, and has been installed by Messrs. W. C. Martin and Co., of Glasgow. The plant includes two sets of direct-acting engines and dynamos, and each section of the ship will be lighted by interchangeable appliances. The mast and side lights are on Martin's patent duplicate electric system.

Building Trades' Exhibition.—This annual exhibition has been held during the past ten days at the Agricultural Hall, Islington, and was chiefly noticeable for the almost complete absence of electric lighting exhibits, the only show worthy of the name being that made by Mr. Harry South, of Garrick-street, Covent-garden, who, in conjunction with the Coalbrookdale Company, had on view some handsome fittings and apparatus. Altogether this stand was an admirable one. A large group of exhibits interesting to those connected with building trades were on view, and there seems no reason why, with liberal treatment from the organisers of the exhibition, electric lighting firms should not be induced to lend their support, which is much needed. There was an absence of life which a few artistic electric light displays would do much to improve. Mr. Joseph Lewis, of Great Winchester-street, showed a number of lightning conductors, bells, and electrical sundries.

Brisbane (Queensland).—A deputation from the Brisbane Municipal Council recently waited upon the Hon. H. M. Nelson, chief secretary, to ask that the Government would introduce a bill giving the Council control of the electric wires in the city. There are already a large number of wires stretched over the city under no control whatever, except in the case of the telephone wires, which are controlled by the Electric Telegraph Department. The electric light wires are becoming so numerous that the Council think some authority should be exercised before the matter becomes more serious. The question of the municipal authority taking up the question of electric lighting was pressing, and with the Government's assistance it was proposed that a bill should be brought forward dealing with the subject. It was pointed out that the Tramway Company intended to introduce electricity as the motive power for their lines, which would necessitate the opening up of the roads, over which the Council has at present no control. Mr. Nelson has promised to introduce the matter on the earliest possible occasion.

Cheltenham.—After considerable delay, a special meeting of the Town Council, held last week, definitely decided to accept the tenders of Messrs. Galloways (Limited), Manchester, for two boilers at £438. 15s. each, and the tender of Messrs. Siemens Brothers and Co. for high-speed engines (Willans) and alternators at £4,610 (less £365 for boilers). The resolution was not, however, carried without considerable opposition.

Coatbridge.—Lord Kelvin has consented to open the central station which has been erected here by the House-to-House Company. The ceremony is to take place to-morrow (Saturday), when a large gathering is expected. The Town Council are negotiating for the light for the Municipal buildings, and it is expected that current for 500 incandescents and 8 arcs will be required. The wiring and fitting of the buildings has been entrusted to Messrs. Anderson and Munro, of Glasgow.

Church Lighting.—Messrs. H. F. Joel and Co. forward us neatly printed particulars of the lighting of the church of St. Nicholas Cole Abbey, Queen Victoria-street, London, E.C.—It has been decided to light Christ Church, Blackpool, by electricity.

Dundee.—Mr. Mitchell, Chairman of the Finance Committee of the Gas Commissioners, has reported that for the year ending the 15th inst. the revenue from the electric lighting works had amounted to £2,644, including £92 from meter rents, £2,384 of this sum had been realised from private lighting, and £167. 10s. from public lamps. At the time when the electric lighting scheme was gone into, a revenue of £2,000 and meter rents £35 was estimated, so that the result shows a considerable increase in revenue.

Finchley.—The scheme for lighting the Finchley Board Schools by electricity, at an estimated cost of about £700, has been abandoned.

Glasgow.—Messrs. D. and G. Graham have just completed an arc lamp installation in the grounds of the Celtic Football Club at Park Head, consisting of sixteen 2,000-c.p. arcs, arranged in three rows of four lamps, and two lamps at the top and bottom of the football field. This plan will enable the lamps to be swung round and used for illuminating the cycle and running tracks which encircle the football ground.

——— The Barony Parochial Board have rejected the proposal to adopt the electric light for the recreation hall and dining hall of the Asylum at Woodielee, which was estimated to cost £562. 13s. 8d., the estimate having been prepared by Messrs. Anderson and Munro. An amendment that gas be used was carried by 15 to 4.

Hanley.—In reply to questions as to the probable date for the completion of the electric lighting works, the Mayor informed the members at the last meeting of the Town Council that delays had occurred which they had not anticipated, but it was hoped that the scheme would be completed by the end of March.

Kingston.—The Lighting and Market Committee of the Corporation at their last meeting resolved to purchase a dynamo and connections for use during the daytime, at an estimated cost of about £240. Messrs. Willans and Robinson have written the Corporation alleging infringement of their patents in regard to the bed plate and crank chamber of the engines in use at the electricity works, and Messrs. Siemens Bros. and Co. have written acknowledging their liability to guarantee the Corporation against any claims in respect of patent rights and royalties on the plant.

Llandudno.—The electric lighting question has recently been under the consideration of the Llandudno Commissioners, who, whilst approving the general idea of the formation of a local company, have requested the promoters to submit a draft of their Provisional Order, together with a draft agreement showing the terms upon which they propose the Commissioners should ultimately have power to purchase the undertaking, upon receipt of which the Commissioners will give the matter further consideration.

London County Council.—At its next meeting a motion is to be made that the Highways Committee consider the advisability of widening the footways of the Victoria Embankment, in order to allow the electric light standards to be placed on the sides of the carriage-way. It will be remembered that the Council rejected the proposal to have the lamps in the centre of the roadway.

Digitized by Google

MANCHESTER.—The question of lighting the workhouse at Crumpsall by electricity is under the consideration of the General Purposes Committee of the Board of Guardians.

MEDICAL QUACKS.—Another medical quack has been laid by the heels, this time at Liverpool. At the recent Assizes Francis M'Conville, trading as "Professor Hamilton," was charged with obtaining money under false pretences. It appeared from the evidence that an Irish labouring man had been induced by the specious representations of prisoner to part with £52. 12s. of his earnings, in order to procure relief by means of a so-called electro-pathic belt. After a patient hearing prisoner was sentenced to five years penal servitude, the maximum penalty. An investigation of his books showed that he was making between £3,000 and £4,000 per year, and was spending large sums on advertising.

NEW SWINDON.—The General Purposes Committee of the Local Board have received the report of Mr. Aldridge on the electric lighting question, which has been referred back to the Electrical Committee for their report as to the advisability or otherwise of applying for a Provisional Order.

SCARBOROUGH.—It has been decided to light the theatre at Scarborough Spa by electricity, and the general adoption of the electric light at the Spa is under consideration, and is likely to be carried out immediately.

SOUTHPORT.—At a special meeting of the Southport New Infirmary Committee to consider the question of the lighting of the buildings now in course of erection, a strong effort was made to induce the Committee to install the electric light, which it was estimated would cost about £1,500 in excess of the estimate already provided for gas lighting. It was, however, ultimately decided that gas lighting should be adopted.

SUNDERLAND.—A resolution will be moved at the next meeting of the Board of Guardians recommending the appointment of a committee to consider the advisability of lighting the whole of the workhouse buildings by electricity.

WESTON-SUPER-MARE.—An influentially-signed memorial has been presented to the Town Commissioners asking that body to immediately take in hand the lighting of the district by electricity. The memorial was discussed at the last meeting of the Commissioners, and an Electric Lighting Committee was formed to take the matter into consideration.

COMPANIES' MEETINGS AND REPORTS.

W. T. Henley's Telegraph Works Company (Limited).

The 15th ordinary general meeting of this Company was held at the offices, Martin's-lane, Cannon-street, on the 22nd inst., Mr. Sydney Gedge presiding.

The SECRETARY (Mr. G. H. White) having read the notice convening the meeting, the report was taken as read.

The CHAIRMAN: The report and balance-sheet are in your hands, and are signed by the auditors. The summary thereof is printed and annexed to the report, and you see the auditors' certificate at the foot. I think, considering all the circumstances of last year—the general depression of trade and the want of enterprise, resulting, apparently, from a want of confidence—we may congratulate ourselves that this Company has so good a report and balance-sheet to show as has been presented to you. There is very little in either to which it is necessary for me to call your special attention. You see that we have reduced the "B" debentures, which were £30,000 only two years ago, to £12,000 only, £4,000 having been paid off within the year. You see that we are able to pay 7 per cent. on the Preference shares, and a dividend of 5 per cent., free of income-tax, on the Ordinary shares, and that there is a very large sum which stands to reserve against investments, etc.—£46,019. The reason of that is this, that we have a very large investment in the International Cable Company, the liquidation of which is now nearly completed, and we thought it right, not knowing exactly how much would come back to us, to make a very liberal reserve. That matter will now be settled in the course of a few weeks, and we shall then know exactly how we stand. The other item of reserve under cable repairing contract, £1,723, represents the accumulation of the sum of £700 a year paid by the Government of the Bahamas, and invested in the joint names of the Crown Agents of the Colonies and your Chairman, in order to provide a fund wherewith to make the repairs of that cable should it be necessary to do so. It is very gratifying to us to know that the cable, which has been laid for two years, has not required to be repaired. The cable which we laid some time before that, between Halifax and Bermuda, has also never required the expenditure of a shilling on repairs, and we hope that the same will be the case with the other cable. If so, a very large proportion of our accumulations will at the end of twenty years come back to the Company as a good "plum," which I hope some of us will live to enjoy. The competition during the past year has been very great indeed, and with 2¾ Consols at or above par, it is not to be wondered at that there is great competition to make small profits of 4 per cent., 5 per cent., or 6 per cent., consequently, our profits are not quite so large on orders as they used to be. And there is another thing that makes our returns not so good as they would otherwise be. We do nothing but the best work, and are determined that as far as we are concerned there shall be no danger of our work being badly done. If we would give inferior work we should get more orders, but we feel that we are doing our duty to our shareholders and ourselves in maintaining the character of our work. The extension of our works has cost just under £16,000, for which £15,000 was raised by issue of Preference stock. The works are now in very first-class order. We are using electrical motors for a great portion of our new works, and although there are larger works, there are no more complete or efficient anywhere. This brings me to the question of finances. We should be glad of rather more capital, and the question is how can it best be obtained? The Directors have not come to any formal decision on the matter, but it has been talked of, and the consensus of opinion is that the best mode will be as follows:—The shareholders are aware that we have applied to the Stock Exchange for a quotation. The application has gone in; all the necessary alterations are made in our Articles of Association, everything in the way of declaration, statutory or otherwise, which the committee of the Stock Exchange require has been duly made, and the papers are lodged. Therefore, when it pleases the committee to take the matter into consideration we hope to get a quotation. Our shares, which a few years ago were a drug in the market at 3, it is now difficult to get at 7, or 8. I have lately bought some for a friend and have found it difficult to get them at between 7 and 8; and I believe that if we can put them in the ordinary way on the Stock Exchange, and get a quotation in the papers, they will soon arrive at par or very nearly par. I want to show you how we can bring them over par. The indebtedness of the Company is £10,000 on mortgage at 4½ per cent., and £15,000 of "A" debentures at 5 per cent. which have to be paid off in September, 1899. We shall, therefore, just finish the century by paying them off. There were £30,000, but there are now only £12,000 of "B" debentures at 6 per cent., which have to be paid off on September 1, 1896—two years and a half hence. The total, you will see, is £37,000, and the total interest paid on this amount is exactly £1,920. In considering the large sum expended on the works extensions you will remember that that is a sort of net sum, because there have been no contractors' profits. The additions have been effected by our own workmen, under the control of our manager at the works, Mr. Hatton, and they therefore really represent in that way more than the £16,000 which they have cost. We consider that our works and undertaking would form an exceptionally good security for a loan of £50,000 in debenture stock, which stock can be issued most certainly at 5 per cent. and, I hope, at 4½ per cent. We shall consult our brokers on this. Our idea is that we should take power when the thing is ripe by applying to the shareholders for authority to issue £50,000 on debenture stock redeemable at a small premium at the option of the Company in a certain number of years, as we may be advised by our brokers, and with the money pay off our first mortgage and our "A" and "B" debentures. The result would be this—that even supposing we could only get this loan at 5 per cent., 5 per cent. on £50,000 is only £2,500 as against the £1,920 we are now paying, or £580 more, but we should have £13,000 ot additional capital, by which we could make more profits. If we could raise the loan at 4½ per cent. the amount of interest would be so much less. Having this capital we shall be able to increase our business and avail ourselves of opportunities that present themselves of buying gutta percha, india rubber, and copper when the materials are favourable in price, instead of having to get supplies in when we want them. Then we should get this advantage—that we should only have to pay out of our profits the interest on our debenture stock, amounting to about £2,250, and the dividends on our Preference shares. The Ordinary shareholders would divide all the surplus profits. At present they cannot do so, because when the "B" debentures were issued, it was agreed that only 5 per cent. should be paid to the Ordinary shareholders, and that all the rest should go to replacing the debentures. Gentlemen present will see what a difference it would make next year or the year afterwards if we were to make £11,000 whether we were limited to paying 5 per cent. or could divide the balance over and above the interest on the debentures and Preference shares. Taking it at £2,250 a year for the one and £2,100 for the Preference shares, that would make £4,350, and all the balance would go as dividend to the Ordinary shareholders; and every £700 of additional profit would be 1 per cent. more. If we were to pay 7 per cent. on our Ordinary shares it ought to make them stand at a premium. I have thought it best to prepare the shareholders' minds for this proposal, because so much can be done by themselves. I know of an hotel company that raised £100,000 by Four per Cent. Debenture stock, and nearly the whole of it was taken up by their own shareholders, and we hope that when a financial operation of this kind comes on you will assist in subscribing for what you will know is a very first-class stock. This is pretty nearly all that I have to lay before you, but before I sit down I wish to say two things—first, that our profits have been made out of ordinary commercial business. You would be surprised if you saw the extent to which our connection has increased and the number of orders that come in each week from different quarters. It is not well that I should state the amount of the orders, but I may say that over 100 orders from different people come in each week, so you see that the average amount of each order is not very large. It is by paying attention to details that we are able to make our profits; and if we get some first-class cable-laying job, as we have had before, we shall have a very good state of things indeed to submit to you. Since the 1st January orders have come in which show that if they maintain the same rate we should exhibit an increase of 30 per cent. in our business, which would mean a good deal more profit. The next thing that I desire to mention is this—that the Board could not have set before you the satisfactory result they do had they not been ably assisted by all the officials of the Company, both in London and at North Woolwich, and the thanks of the shareholders are due to those gentlemen. With these remarks I move—

"*That the report and balance sheet now presented to the meeting be received and adopted.*"

Digitized by Google

Mr. R. J. JENKINS, C.E., seconded the resolution. The Chairman had laid great stress on the advantage which would accrue to them if they were to issue one solid stock to replace the mortgage and debentures which at present existed. That must be apparent to all of them. The Board had been considering this matter for some time. The proposal would increase the capital of the Company by £13,000, but the Company had not a reserve which was a money reserve at the moment, and they required capital in order to enable them to make purchases and get discounts. Their Managing Director (Mr. Sutton) had told them that he could have secured parcels of gutta percha and other things required in the course of trading on advantageous terms had he had the means. The financial operation to which reference had been made would not injure, but would strengthen them, because they would feel themselves perfectly safe with this Debenture stock rather than with debentures which they might be called upon to pay at perhaps an inconvenient time. They had done a considerable amount of work, but it was not as profitable as the making and laying of cables. When they got into larger enterprises — such as the Bahamas, and the Halifax and Bermuda cables—there were profits which they were entitled to on account of the greater amount of risk. There were, at the present time, one or two cable projects before them, one of a rather important nature for a Foreign Government, and in the course of the present year they hoped they might obtain the order for one of these. They would all regret the absence of General Hutchinson, who had been seriously ill.

Mr. MICHELL said he thought the financial scheme shadowed forth would commend itself generally to the appreciation of the shareholders.

The motion was then adopted unanimously.

The CHAIRMAN next proposed the payment of dividends mentioned, that on the Ordinary shares to be free of income-tax.

The Hon. RANDOLPH STEWART seconded the motion, which was carried.

Resolutions were afterwards passed, re-electing the retiring Directors: Mr. Fredk. Newton and General George Hutchinson; and the Auditors: Messrs. Ball, Baker, Deed, Cornish, & Co.

Votes of thanks were then passed to Mr. R. J. Hatton, and the staff at North Woolwich and London, and to the Chairman and Directors, and the proceedings terminated.

House-to-House Electric Light Supply Company (Limited).

The sixth ordinary general meeting of this Company was held at the works, Richmond-road, on Thursday last week.

Mr. HENRY R. BEETON presided, and in moving the adoption of the report, stated that there was a steady growth in the business, and greater progress was made last year than in 1892. The general depression in trade had affected them, as possible consumers held back from adopting electric light. The income per lamp had fallen off, this being partly due to the absence of fog and partly to consumers being more economical in their use of current. It was satisfactory, however, that the Company had earned £1,421 more than in 1892, while the working expenses were £19 less. The capacity of the station, exclusive of reserve, amounted to 45,000 8-c.p. lamps, which was considerably in excess of the immediate demand. The nothern division of the area of supply had been transferred to the local authority.

The motion was carried unanimously, and a dividend of 7 per cent. on £25,000 Cumulative Preference shares was declared.

The following is the Directors' report:—

The revenue account for the year ended December 31, 1893, shows a credit balance of £4,231. 4s. 2d., which, with the sum of £525 guaranteed by the Leeds and London Electrical Engineering Company (Limited), referred to in another paragraph, and the balance, £40. 14s. 3d., brought forward from the previous year, makes a total of £4,796. 18s. 5d. After deducting £1,800 for interest paid on £30,000 Debentures, it is proposed to deal with the balance as follows:—In reduction of preliminary expenses, £500; in reduction of suspense renewals account, £100; depreciation fund, £700; dividend of 7 per cent. on £25,000 Cumulative Preference shares, £1,653. 10s. 2d.; balance carried forward to next account, £43. 8s. 3d.—£2,996. 18s. 5d.

That the Company's business has continued to increase is shown by the following table from January 1, 1890:—

Date.	Equivalent of 35 watt lamps ctd.	No. of houses connectd.	Ordinary revenue.	Revenue from construction business.	Total revenue.	Expenditure.	Profits.
Dec. 31,			£ s. d.	£	£ s. d.	£ s. d.	£ s. d.
1890	13 665	248	5,010 9 2	—	5,010 9 2	4,624 6 5	386 2 9
1891	19,383	373	8,328 3 11	—	8,328 3 11	6,077 14 10	2,250 9 1
1892	23,700	471	10,688 13 6	525	11,213 18 6	7,851 19 6	3,361 19 0
1893	28,429	599	12,063 10 10	525	12,588 10 10	7,832 6 8	4,756 4 2

It is most satisfactory to observe that, whereas the revenue derived from the sale of current shows an increase of £1,421 over last year, the working expenses show a decrease of £19.

Since the issue of the last report another engine and alternator have been laid down, bringing the capacity of the station, exclusive of reserve, to 45,000 8-c.p. lamps.

The balance of the issue decided on, of £25,000 Seven per Cent. Cumulative Preference shares, has been subscribed during the past year.

The guaranteed sum of £525 has been credited in account by the Leeds and London Electrical Engineering Company (Limited), for the year 1893, in connection with the business of Central Station Construction which that Company took over.

The Directors are pleased to report that the application to the Board of Trade to revoke that portion of the Company's Provisional Order which referred to the Northern division of the area of supply has been successful, and the Company are now released from their obligation to lay mains in that district.

Mr. Robert Hammond has retired from the Board, and has been appointed consulting-engineer to the Company. The Directors received with regret last year the resignation of their Manager, Mr. Albert Gay, on his appointment as Resident Engineer to the Vestry of St. Mary's, Islington. They have appointed Mr. Henry W. Bowden as chief engineer, and have every reason to be satisfied with their selection. Mr. W. F. Leese and Mr. W. R. Davies retire from the Board by rotation, and being eligible offer themselves for re-election. Messrs. Theobald Bros., Miall & Company the auditors of the Company, retire, and submit themselves for re-election.

Chatham, Rochester, and District Electric Lighting Company (Limited).

The annual general meeting of this Company was held on the 20th inst. at the works, Whittaker-street, Chatham, Mr. Henry Jasper presiding.

The CHAIRMAN, in moving the adoption of the report, said they had anticipated that a large number of lights would have been taken up, but it would seem that many people did not care to go to the expense although the cost had been much reduced. They would see by the report that a large number of consumers had adopted the meters, and had found them very satisfactory and very reliable, so much so that those who had them had put in additional lights. Consumers also felt they were not paying for the light unless they used it, which was as it should be. He had no hesitation in saying that before the close of the year every one of their customers would have meters. The price of lamps had much reduced owing to royalties falling through, and they were also supplying a much superior lamp, which was also of advantage to the consumers. Those items all tended in the direction of making the light more in favour with consumers than it had been in the past. They had no doubt heard at different times people expressing their doubts about the undertaking. He was happy to tell them that they had turned the corner—in fact, they had done a great deal more, as they had a great number of new customers since December 31st, and had a very fair number coming in now. They were young yet; they had not been in existence six years, and although it might be thought that it had taken them a long time to get themselves in order, it must be remembered what had been done in those six years elsewhere—what had been done in London and other parts of the country. The electric light was becoming very popular in London; there the companies had very large outputs, and were charging very much higher prices than they were. Their position was therefore very favourable, as their charge was 4½d., whilst the lowest price in London was 6d. and 7d., and even more, and yet the light was making great progress. The Directors had been somewhat disappointed with regard to the effort to obtain money on debentures. They wanted more money in the concern, so that they might extend it. They had the plant and machinery there, and felt justified in hoping shortly to make such extensions that their income must be increased very considerably. The Chairman then alluded to the ability of the Managing Director (Mr. Hurrell), who had brought them to the excellent position they were in. If they had been better guided in the first few years they would have been in a much better position, and had they had the benefit of his skill and ability they would have paid a dividend in two or three years. The Directors had decided not to recommend the payment of a dividend, although they had earned sufficient to pay 2½ per cent. They did so from the fact of the Debenture stock not being applied for, which showed rather a want of confidence on the part of investors.

Mr. GEORGE CHURCH seconded the motion, which was carried.

Motions for the re-election of Mr. W. King as Director, and of Messrs. G. F. Butts and J. E. Ratcliff as auditors, having been carried, a vote of thanks to the Chairman concluded the proceedings.

Hastings and St. Leonards-on-Sea Electric Light Company (Limited).

The annual general meeting of this Company was held on the 20th inst. at the Brassey Institute, Hastings, Mr. H. M. Baker presiding.

The CHAIRMAN, in moving the adoption of the Directors' report and balance-sheet, said those who were present at the last meeting might remember that attention was called to the fact that during the current year it would be necessary to call up a considerable amount of capital to carry on the largely-increased business. If they compared the balance-sheet with that of last year they would find that the Directors had called up £5,230 during the year, and that their revenue had increased from £4,276 to £5,390, or an increase of £1,114, a little more than 25 per cent. Although that was satisfactory so far as it went, it was only fair to say that it would have been very much more so if it were not that a considerable amount of expenditure would be realised during the current year, and notably that in connection with the lighting of the whole of the Front. As they were aware, the Front would not be lighted to the full extent until midsummer, and he would like to take that opportunity of publicly stating the fairness with which the Corporation had met them in all their transactions, and notably as regarded the increased electric lighting on the Front.

Digitized by Google

The next point that he would refer to was, to the minds of the Directors, a most important one—in the interests of the Company they had decided to engage the services of Prof. Kennedy. They had appointed their sub-manager, Mr. M. G. Ross, to the vacancy caused by the unfortunate death of Mr. Mercer; and they had also been fortunate in retaining the services of their secretary. At the end of that meeting a special meeting would be held to consider the best means of coping with the increased demands for the electric light they were receiving on all hands. Under the Provisional Order granted them by the Board of Trade, by which they had to supply the whole of the district, there were certain conditions which, sooner or later, they would be called upon to fulfil.

Mr. SHORTER seconded, and the motion was carried.

The retiring Directors, Messrs. Langham, Reeves and Woodhams, were re-elected; the auditors were reappointed; and a vote of thanks to the Directors concluded the proceedings.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

ALTRINCHAM ELECTRIC SUPPLY (LIMITED).—This Company was registered on March 22nd, with a capital of £50,000, in £1 shares, to take a transfer from the Manchester Edison-Swan Company (Limited) of a Provisional Order granted to them by the Board of Trade, and confirmed by the Electric Lighting Orders Confirmation (No. 4) Act, 1893, authorising the undertakers to produce, store, supply, and sell electricity, electric current, and other like energy for public and private purposes within the Local Board districts of Altrincham and Bowdon, in the parish of Bowdon, in the county of Cheshire; to adopt, complete, and carry out a provisional agreement to be made between the Manchester Edison-Swan Company (Limited) of the one part, and this Company of the other part, for such transfer; and to carry on the business of electricians, electrical engineers, and suppliers of electricity in accordance with such powers. The subscribers (with one share each) are:—W. J. Crossley, C. C. Dunkerley, W. P. J. Fawcus, H. T. Gaddum, W. O'Hanlon, W. Warburton, and W. A. Arnold. The first Directors are:—William J. Crossley, Charles C. Dunkerley, William Paul, James Fawcus, Henry T. Gaddum, William O'Hanlon, and E. J. Sidebothom.

ELECTRIC TRACTION COMPANY (LIMITED).—This Company was registered on March 22nd, with a capital of £300,000, divided into 29,880 shares of £10 each, and 1,200 shares of £1 each, to enter into contracts for the construction, repair, and maintenance of and to construct, equip, repair, and maintain any works, including railways, and other roads and ways, to be used for traction by electricity, steam or other power, to lay down pipes for the distribution of electricity, or for telegraphic or telephonic communication, and to carry on the business of electrical engineers, mechanical engineers, railway and tramway proprietors, suppliers of electricity, and other like business. The subscribers (with one share each) are:—E. T. Botwright, F. P. Shuckard, W. H. Adams, H. D. Brooke, W. B. Butler, W. Y. Yeoman, and G. Dewdney. The first Directors are to be appointed by the above-named signatories to the Memorandum of Association.

ROWLAND BARNETT AND CO. (LIMITED).—This Company was registered on March 20th, with a capital of £20,000, in £1 shares, to purchase, or otherwise acquire, the business of an electrical and mechanical engineer, carried on by Rowland Hill Barnett at Walker Gate, Northumberland, and 8, Moseley-street, Newcastle, under the trade style of Rowland Barnett and Co., with a view to such acquisition, to enter into and carry into effect the agreement with the vendor referred to in Clause 3 of the Articles of Association, and to carry on the business of electricians, electrical engineers, mechanical engineers, suppliers of electricity, the general business of an electric company, manufacturers of, and dealers in, all apparatus and things required for or capable of being used in connection with the generation, distribution, supply, accumulation and employment of electricity, iron and brass founders, tool makers, metal workers, millwrights, machinists, &c. The subscribers (with one share each) are:—R. H. Barnett, H. A. Westmacott, C. A. Woods, F. R. Fenwicke, C. Liddell, J. Cowper, A. W. Dixon, and J. R. Glass. The first Directors are Messrs. R. H. Barnett and H. A. Westmacott.

CITY NOTES.

ANGLO-PORTUGUESE TELEPHONE COMPANY (LIMITED).—The seventh ordinary general meeting of the shareholders of this Company was held yesterday at the offices, 53, New Broad-street. Representatives of the Press were not admitted. The Directors' report for the year ending December 31st last states that the amount to the credit of profit and loss is £6,171. 16s. 9d., which is carried forward to the current year's account, the declaration of a dividend being, on the advice of the Company's solicitors, postponed for the present. The report shows an increase of 80 in the number of subscribers, and in value of £721 over the preceding year.

CENTRAL LONDON RAILWAY.—It is announced that the prospectus of the Central London Railway Company is to be issued immediately by the Exploration Company. The Company is to construct two tunnels from the eastern angle of Shepherd's Bush Green, *viâ* Oxford-street, to Cornhill, E.C., and to connect the Mansion House to the Great Eastern Railway Station at Liverpool-street, giving a total of 6¾ miles. There are to be 14 stations on the line, which is to be worked entirely by electricity.

CHARING CROSS, EUSTON, AND HAMPSTEAD RAILWAY.—The prospectus is issued inviting applications for £1,416,000, in £10 shares. The Company has, in addition, power to raise £472,000 in Four per Cent. Debentures. The railway is to be about five miles in length, and is to run from Charing-cross, passing under King William-street, Charing-cross-road, Tottenham-court-road, Hampstead-road, Haverstock-hill, to the junction of High-street with Heath-street, Hampstead; a short branch from the Hampstead-road is to connect the Euston Station with the new line. Two separate tunnels are to be constructed under the Greathead system, and the motive power to be employed is electricity. The list of applications closes on Tuesday next.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended March 25th were £792, as against £859 in the corresponding period of last year, being a decrease of £67. The total receipts for the half-year amount to £11,191, as against £11,271 for the corresponding period of last year, a decrease of £80.

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY (LIMITED).—The prospectus will be found elsewhere of this Company, which is formed with a share capital of £800,000, divided into 40,000 Preference and 40,000 Ordinary shares of £10 each, and the Directors have, in addition, power to raise £400,000 of Debentures. The present application is for 19,900 Ordinary shares of £10 each, offered for subscription at par by the Electric and General Investment Company (Limited), on behalf of the County of London Company. The instalments are payable £1 on application, £1 on allotment, and £2 on June 30, October 1, and December 31, 1894, and March 30, 1895. The Company was registered in June, 1891, for the purpose of undertaking the supply of electricity in certain districts in the county of London, and in the United Kingdom, where capital may be profitably employed in electric supply. The Provisional Orders already obtained include the united parish of St. James and St. John, Clerkenwell, St. Luke, Middlesex, the district served by the Wandsworth Board of Works, and the parish of St. George the Martyr, Southwark. In addition, the Company will undertake the erection and equipment of power stations in provincial towns where municipal authorities have obtained Provisional Orders, which they are prepared to transfer to a responsible company; and, in addition, the Company proposes to assist local companies with capital, &c. Work is to be at once commenced in the St. Luke, Clerkenwell, and Wandsworth districts, and a controlling interest is to be acquired in the local electric supply companies at Bournemouth, Dover and Canterbury, whilst at Shrewsbury, Bedford, Weston-super-Mare, and other towns, negotiations are in active progress. All contracts entered into by the Company are fully disclosed in the prospectus, which contains no waiver clause. Applications for shares must be made on the form accompanying the prospectus, which can be obtained from the bankers, Messrs. Glyn, Mills, Currie & Co., 67, Lombard-street, E.C.; the brokers, Messrs. Foster and Braithwaite, 27, Austin Friars, E.C., and at the offices of the Company, 49, Queen Victoria-street, E.C.

EDISON GOWER-BELL TELEPHONE COMPANY OF EUROPE (LIMITED).—The eleventh ordinary general meeting of this company was held at the offices, 53, New Broad-street, E.C. yesterday. Representatives of the Press were not admitted. In their report the Directors state that to December 31st last there was a balance to the credit of revenue account of £120. 6s. 10d., which it was proposed to carry forward.

MESSRS. EVERED AND CO. (LIMITED).—The Directors of this Company recommend that, after payment of Debenture interest and writing off the usual amount for depreciation, a dividend at the rate of 7½ per cent. per annum be paid for the half-year ended December 31st last, making 7½ per cent. for the whole year. £2,000 is placed to the building fund, £2,026 carried forward.

LONDON REFUSE STEAM GENERATOR AND ELECTRICAL POWER CORPORATION (LIMITED).—Interesting correspondence and articles dealing with the prospectus of this Company (which was referred to in our last issue) have appeared during the week in the *Pall Mall Gazette*. It is noticeable that no indication has been given by the Company as to whether the subscription to the issue of capital was sufficiently large to warrant the Directors in proceeding to allotment.

ROCKHAMPTON (QUEENSLAND).—The Directors of the Rockhampton Gas and Coke Company have issued their report, and announce that their electric light operations for the past year show an actual loss of £21, to which is added £294 brought forward. During the year they have carried out the lighting of the Fitzroy Bridge, and have received a notification from the Governor in Council expressing his satisfaction at the electric lighting work carried out by the Company. A similar approval has been received from the Rockhampton Municipal Council, and, as such a proof is necessary under the Companies Act for supplying the electric light in the district, the Directors express their satisfaction. From the profits of the general business of the Company a dividend of 10 per cent. has been declared.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED). It is stated that the whole of the £30,000 Four per Cent. Debentures, recently issued by this Company, have been applied for and allotted.

WEST END LIGHTING.—The following delightfully vague paragraph appears in the *Glasgow Herald*, and shows the enterprise of its London correspondent:—"A powerful syndicate is about to be formed, with the support of one of the Rothschilds, with the view of applying for and putting into operation provisional orders for lighting by electricity some of the large and fashionable suburbs of London."

Digitized by Google

WATERLOO AND CITY RAILWAY.—The capital of this Company has, we understand, been satisfactorily placed, the shares applied for being largely in excess of the number required. Letters of allotment and regret have been posted.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended March 23rd (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited) were £2,735.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 829.—Vol. XXXII. FRIDAY, APRIL 6, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

Our New York Correspondent has already prepared our readers for the epoch-making discovery of Mr. C. F. Scott. He has evolved a system of alternate-current working, which consists of the combination of a two-phase with a three-phase arrangement. In another column we print an abstract of this Paper, the abstracting having been done with such reverence as befits the importance of the subject. It is difficult to appreciate the value of land-marks of history until time has allowed a true perspective view to be obtained, but Prof. Rowland joined with Prof. G. Forbes in the discussion at the National Electric Light Association, in proclaiming Mr. Scott's device as "one of the finest things that have come out in recent years in this [*i.e.*, U.S.A.] country." The "exceedingly interesting Paper," the "beautiful arrangement," "an extremely beautiful idea" which "appears on the face of it to be a feasible method" (a little bathos here), for which Prof. Forbes expressed his admiration, must, of course, be studied by alternate-current men in its entirety. Meanwhile, we hope that our abstract will suffice for plain continuous-current men, who may be thankful to see what they escape.

The Paper by Mr. Mordey on parallel working of alternators was justified as a "personal explanation" in reply to a statement made some time ago by Prof. Forbes. Neither the Paper nor the discussion has added anything to the subject, except, indeed, an analogy or two, which is always useful. We described the original experiments three years ago, and the recent tests have done nothing more than to confirm them. The suggestion that the hunting was due to the decrease of resistance of the lamps is interesting, and is quite as likely to point to the true cause as the more commonplace reference to the governor. If a fraction of the time and trouble spent over this Paper and its discussion had been devoted to the consideration of alternators, which, on account of the engines which drive them, or for other reasons, cannot be run in parallel, something more useful than clearing the character of the Mordey alternator from an unimportant imputation would have been achieved. We shall be interested to learn whether the gas-engine-driven alternators at Coatbridge will be habitually run in parallel on the ordinary lighting load. We shall not be surprised to hear that parallel running is not wanted at Coatbridge.

We are glad to learn that a Committee of the Trinity House has recently visited the French coast for the purpose of examining some of the important developments which have been made in the use of the electric light for lighthouses. One of the chief characteristics of the French system is the use of *feux éclairs*, or quick flashes, which were described in our leading article on September 1, 1893. On that occasion we pointed out the great advantage of rapid revolution of an optical apparatus of few panels, as compared with the slowly revolving arrangement of many panels as used on our coasts. The importance of the French system can only be fully appreciated during fogs sufficiently thick to obscure the light itself, and to leave only a general diffused light in the direction of the lighthouse. Another feature of French practice is the use of genuine arcs of 45 volts, exposing the bright surfaces of the carbons, instead of the 35 to 38 volts used at St. Catherine's Point. Besides these two highly-important details, there are many other points on which co-operation is desirable, and it is gratifying to learn that the Committee was received by the Lighthouse Department of the Ministry of Public Works with great cordiality.

In our issue for March 16th (p. 557) we gave the charges for telephone service in many of the more important cities of Europe. We have received further information confirming most of the figures already published, but partly supplementing and partly contradicting them. Besides the £8 service in Paris, which appears to be for overhead lines, there is a £16 service for underground lines, and, as in many continental cities, a charge per kilometre for lines extending beyond the local exchange area. In Marseilles there is a £12 underground service in addition to the £8 service. The tariff in Italy for districts with more than 100,000 inhabitants is £12, and for other districts £6. The items which go to make up the charge at Vienna amount to £10, and not £5, as was given by mistake in our recent article. The charges in Russia vary from £39 to £23. 15s. per annum. The rates for the Metropolitan are £20, but under a five years' contract which contains several stringent conditions, a rebate of £3 is allowed. Second and additional connections are made for £15, or for £12. 10s., under a five years' contract; private house connections £12 and £10 respectively. These rates are for connection within one mile of the nearest exchange, and enable a subscriber to speak to any other in the Metropolitan system, which extends over 500 square miles, equivalent to a circle of about 12½ miles radius. We willingly publish this information, but cannot

Digitized by Google

admit that the rates compare favourably with those in other countries. It is true that a Metropolitan subscriber enjoys a vast potentiality of communication with any one of thousands of subscribers; but he generally wants to speak to only 50 or 100, as is evidenced by the list which is, as a rule, to be found hung up near a telephone. He has to pay for the privilege of unlimited talk whether he avails himself of it or no.

It has been suggested to us that in Paris and elsewhere, the subscribers have to purchase their instruments, while in this country they are provided by the telephone company. We cannot admit that this is a valuable concession. A telephone is such a nuisance, though perhaps a necessary nuisance, that it is very common to place the main instrument in the clerk's office for general use, and to provide a desk instrument in the private office. But the annual charge, namely, £2. 2s. for a wall instrument, or £2. 12s. 6d. for the desk, is about the same as the retail price at which any subscriber could, if he were allowed, buy the apparatus outright for himself. At present he has no choice but to take the instrument which the Company provides, and these have almost invariably been fitted with Blake transmitters while better ones were available. If, like the electric supply companies, the telephone company brought their wires up to a pair of terminals, and allowed the subscriber to apply whatever apparatus he liked to them, the service would be much better appreciated.

In alluding last week to the Charing Cross and Hampstead line we innocently remarked, "The promoters state that it is intended to run 'light trains at short intervals,' and a 2½ minute service is promised. This looks as if the Liverpool Overhead Railway arrangements, rather than those of the City and South London line, were to be the pattern." By the Liverpool arrangements we merely meant the general idea of motor cars as against locomotives and the general assimilation of the undertaking to a glorified tramway, and we had no intention of conveying the idea which some of our readers have run away with that the trains at Liverpool actually were lighter or ran more frequently than those belonging to the City and South London Railway Company. As a matter of fact, the two-motor-car "trains" on the Liverpool line weigh when full 38¼ tons and seat 114 passengers, whilst those on the City and South London line weigh 37½ tons and seat 96 passengers. So far so good, but whilst the weight of a full train on the City and South London line is 871lb. per passenger, the figure for Liverpool is only 752lb. per passenger, a gain due to the use of motor-cars in place of the locomotives employed by the plucky pioneer electric railway of the world.

Telephone Trunk Lines.—The telephone trunk wire connecting Berlin with Elberfeld-Barmen came into operation last month.

Personal.—Mr. A. B. Blackburn, M.I.C.E. (late with Messrs. Mather and Platt, Limited), has been appointed chief engineer of the Electric Construction Company (Limited).

Glasgow and West of Scotland Technical College.—It is stated that the Glasgow and West of Scotland Technical College is to receive a donation of £25,000 from the Bellahouston trustees.

Coatbridge.—The electric supply station at Coatbridge was opened last Saturday by Lord Kelvin. The plant at this station is entirely driven by gas power, and the alternate current transformer system has been adopted.

Royal Institution.—At the general monthly meeting of this Institution, on Monday last, the special thanks of the members were returned for the following donations to the fund for the promotion of experimental research at low temperatures:—Prof. Dewar, £50; Hugh Leonard, Esq., £50.

Proposed Tubular Electric Railway in Paris.—The French Government, at the suggestion of M. Jonnart, Minister of Public Works, has placed before the Chamber a *projet de loi* empowering the City of Paris to construct a tubular electric railway connecting the Bois de Boulogne with the Bois de Vincennes. Strange to relate, no State aid is invoked.

The Verband der Elektrotechniker Deutschlands.—This Society is to hold its next annual general meeting in Leipzig from June 8th to 10th. The programme will shortly be published, but notice has been given that Mr. Gisbert Kapp, the proposed General Secretary of the Society, will give an address. An exhibition of electrical novelties is to be held during the meeting.

Cable Interruptions:

	Date of Interruption.
Cayenne-Paramaribo	Oct. 15th, 1893.
Bissao-Bolama	Nov. 24th „
Garachico-Santa Cruz de Palma	Dec. 27th „
Fao-Bushire	Mar. 20th, 1894.
Bonny-Cameroons	Mar. 21st „
Brest-St. Pierre (P.Q. Co.)	Mar. 29th „

Telephonic Communication in Italy.—Negotiations are in hand between the Italian and Swiss Governments with reference to the establishment of telephonic communication between Milan, Como, and Lugano, and other towns in Switzerland. The Telephone Company of Lombardy has also been granted a concession for the establishment and operation of a trunk line between Milan and Monza.

The Telegraph Revenue for 1893-94.—The revenue receipts under the heading of Telegraph Service, amounted for the quarter ending March 31st last to £585,000, as against £555,000 for the corresponding period of the previous financial year. The receipts for the year ending March 31st last amounted to £2,540,000, as against £2,480,000, an increase of £60,000, or 2·4 per cent.

The Goodwin Sands Lightship Telephone.—The first call by telephone from the Goodwin Sands lightship was received at Ramsgate on Wednesday evening last week to the effect that there was a vessel on the Goodwins. The Ramsgate, Deal, and Walmer lifeboats were launched, and it was found that a schooner had run ashore on the north sand head during a heavy fog, but was being assisted off by the Ramsgate lugger "Champion."

Electric Heating.—A new application of electricity to manufacturing purposes is reported from Germany in connection with the use of metal plates for pressing and finishing woollen goods. Such plates, which require to be heated, have hitherto usually been warmed either in an oven or by means of steam, but both these processes are troublesome, and involve loss of time, besides leading to uncertainty as to the temperature obtained. It is now proposed to heat the plates by electricity.

Nickel-Plated Electromagnetic Instruments.—In the current number of the *Zeitschrift für Instrumentenkunde*, Dr. A. Ebeling, of the Physikalisch-Technische Reichsanstalt, calls attention to the danger of nickel-plating delicate electromagnetic instruments. A case recently came under his notice in which a deflection of 8deg. could be produced by rotation of the case of an instrument parallel to the needle which was magnetised. He finds that plating, even when so thin as to be quite transparent, has a very marked magnetic effect.

American Institute of Electrical Engineers.—The American Institute of Electrical Engineers is now issuing advanced postcards which, in addition to giving the title of the next Paper, and the name of its author, gives the name of the member

Digitized by Google

who will open the discussion. The idea is a good one, as the starting of a discussion is often a most difficult business, and many members who would otherwise not take the trouble to attend, would probably be induced to do so if they could make sure that the debate would be set going by a good speaker.

Société Internationale des Electriciens.—The following is the constitution of the Council of this Society for the year 1895-96 :—President : M. A. Potier ; Vice-Presidents : MM. Arsonval, Sartiaux, Sciama ; Secretaries : MM. René Arnoux, A. Bochet ; Treasurer : M. Hippolyte Clérac ; Members : MM. H. Baron, Ed. Bernheim, A. L. Blondel, Julien Boulanger, L. Clerc, E. Desroziers, G. Dumont, Georges Ebel, G. Gaiffe, Ch.-Ed. Guillaume, A. Larnaude, Max de Nansouty, Louis de Place, Jules Pollard, Radiguet, Jules Richard, de Romilly, Gaston Sautter, Léon Violet.

A Proposed International Electrical Exhibition.—An International Electrical Exhibition, to be opened in July, 1895, is being talked of in Paris. The idea is to make use of the Palais des Machines on the Champs de Mars and the Palais de l'Industrie in the Champs Elysées. In the former will be placed the generators, and in the latter the motors, the powers generated on the Champs de Mars being transmitted to the Champs Élysées. The two buildings are moreover to be connected by an electric tramway, and electric launches are to be run on the Seine.

Friday's Aurora and the Telegraph Wires.—The following query has been addressed by Mr. Preece to the editor of *The Times* :—

Sir : There was an extremely brilliant display of aurora between 10 and 10:45 p.m. on Friday, the 30th ult. It was accompanied, as usual, by very strong earth currents on all telegraph lines. But at 10:20 p.m., when all the telegraph circuits were idle, a peculiar frizzling and bubbling noise was heard upon a telephone inserted upon a long Irish wire at Llanfairpwll in Anglesey. At 2 a.m. on Saturday, the 31st ult., "twangs" were heard, as if a stretched wire had been struck. These were followed by a kind of whistling sound. Were these signals from space, or mere disturbances of atmospheric electricity ?

Thunderstorms.— At Ambleside, last Saturday, lightning struck a gas pipe in the church belfry, ignited the gas, and caused a portion of the structure to be destroyed. At Bradford, last Wednesday, two horses in a stable were killed, and a window in the building was shattered, while a stableman standing near the horses was uninjured. On the same evening a house at Danesmoor was struck by lightning, doors and windows were cut to pieces like matchwood, furniture was smashed, and one of the inmates received an electric shock.

The Telegraph Department.—In answer to a question in the House of Commons on Tuesday evening last, the Paymaster-General said the Departmental Committee upon the working of the Telegraph Department were now considering their report, and he had reason to believe that it would be in his hands in a few weeks. The Committee, however, which was mainly intended to inquire into the possibility of introducing economy into the service, would report for the information and guidance of the Department, and it was not consequently certain that their report would be one which could properly be laid before Parliament.

Royal Meteorological Society's Exhibition.—The Royal Meteorological Society's Fourteenth Exhibition of Instruments, which will open on Tuesday next in the rooms of the Institution of Civil Engineers, 25, Great George-street, Westminster, will be devoted mostly to instruments, drawings, and photographs relating to the representation and measurement of clouds. The exhibition promises to be a very interesting one, and will include original cloud sketches by the late Luke Howard, F.R.S., as well as photographs of clouds by the highest authorities in various parts of the world. The exhibition will remain open till the 20th instant.

Electrical Fires.—Mr. William H. Merrill, Electrician of the Chicago Fire Underwriters' Association, has recently issued his second report, giving 77 instances where fires were caused, or said to be caused, by electricity. The list, says the *Electrical Engineer*, of New York, is very interesting and instructive, showing that in nearly every instance the damage could have been prevented by using better wiring material or by exercising a little common sense in the use of the appliances. In one instance, the cause of a fire was as follows :—"Bell wire tapped to incandescent 50 volt alternating circuit by employees in building, cotton and paraffin insulating covering ignited. Loss considerable."

Capt. Abney on Photometry.—At the Society of Arts on Monday last Capt. Abney commenced a course of lectures on Photometry. He disclaimed any intention of discussing the art of gas testing which is so often confused with photometry. The sperm candle of to-day gave less light than when Parliament in its wisdom decreed that the standard of light should be thus defined, because recent chemical improvements had refined the sperm, and in refining it, had removed certain light-giving constituents. Capt. Abney had used the arc as a quantitative standard of white light for upwards of ten years, and he alluded to the "rediscovery" of this source of light as a quantitative standard, but gave no definite information as to the construction of a standard of any given number of candle-power. He predicted that note-book records of photometric work would soon become obsolete, and that photographic records would become general. The experiment described in a Note in our issue of March 23rd, consisting in the focussing of the sun's rays on a candle flame was admirably illustrated by photographs, and it was shown that the light reflected from the small particles was polarised.

Continuous Rails.—An experiment with continuous rails is about to be tried on an adequate scale by the Baden Railway of St. Louis, U.S.A. The railway, according to the *Railway World*, is practically a street tramway, and is undergoing conversion from horse to electric traction. One provision of the contract for the work calls for the welding of all rail joints for a length of three and a half miles of double track. Experiments on a smaller scale on the West End tramways of Boston have apparently proved successful, as far as the strength of the welds is concerned, for the welding company guarantees no breaking ; but that the "creeping" of the rails, and their expansion and contraction under varying temperatures will not make the continuous rail impracticable, has yet to be determined. The tramway company will furnish the current (300 amperes at 500 volts) for welding. Should the results be favourable, one of the most troublesome features of electric traction, where the rails are used for the return circuit, will be removed, and the experiment will be watched with special interest by tramway companies using this form of traction.

The Use of Gas Motors in Germany.—Prominent among the economies which have been introduced during recent years in Germany, writes Mr. F. H. Mason, the United States Consul-General to Germany, in a report on the use of gas motors, is the use of gas motors in place of steam engines in all the smaller forms of manufacture where the motive force required does not exceed 75 to 150 H.P. At the Frankfort Electrical Exhibition of 1891 most of the dynamos were driven by gas and "caloric" engines, and the display of these motors at that time was almost as varied and interesting to the general public as that of the electrical apparatus to which they were technically subsidiary. There were in operation at that time throughout Germany about 18,000 gas motors, with an aggregate motive force of 60,000 H.P. Since then the gradual cheapening of gas and the rapid extension of electrical lighting and electrolysis have combined to increase very rapidly the use of gas motors, the effectiveness and economy of which were so brilliantly demonstrated at the Frankfort Exhibition. No statistics are available to show the precise number that are at present in use ; but, as the two principal makers of gas engines in Germany have alone made and delivered during the past two years 1,950 motors, it may fairly be inferred that the number in actual service in this country is not far short of 24,000 or 25,000.

Zurich Electric Tramway.—On March 5th some sixty people availed themselves of the Directors' invitation to the trial run on this tramway. The line is 4·6km. long, and is of one metre gauge ; the inclines are severe, and reach a maximum of 6·2 per cent. over a length of 115 metres. The rails are laid

Digitized by Google

direct on a stone bed, and weigh about 38kg. per metre. The cars, delivered by the Schweizerische Industriegesellschaft, carry 24–26 passengers; they have each one 18 H.P. Oerlikon motor, of the completely enclosed type, geared by single reduction to the wheels. These cars weigh nearly four tons light, and about $5\frac{1}{2}$ when fully loaded. The conductor is overhead, on iron or wooden poles, and is 7mm. in diameter, and about 20ft. from the ground, and the return is through the rails. These conductors are divided into four pieces, insulated from one another, each section being connected to the station by a feeder of 66 square mm. cross-section. The plant at the station consists of two vertical compound engines of 90 H.P. each, speed, 240 revolutions per minute, driving by belts shunt-dynamos of Oerlikon type XI, giving 66 kilowatts at 550 volts, with 450 revolutions per minute; each of these sets is sufficient to drive the whole system. There is some novelty in the use of accumulators in shunt with the dynamos, to provide the excess current wanted for a moment or two at intervals. The mean current is 90 amperes, and the maximum reaches 200; Tudor cells of 245 ampere hours capacity are used, with an automatic charge and discharge switch. All the electrical plant and fittings were supplied by the Maschinenfabrik Oerlikon. On March 8th the line was opened to the public, who utilised it in extraordinarily large numbers, crowding the cars to an uncomfortable extent.

The Transformation of Mechanical Force into Chemical Change.—A remarkable series of experiments has been carried out by Mr. M. Carey Lea, with the object of ascertaining whether the effects of pressure upon certain substances could be made to yield the same results as light. Mr. Lea began by squeezing the silver haloids, and found these salts were readily blackened in this way, and so gave evidence of partial reduction. It was then tried whether the same agent—mechanical force—would be capable of bringing about analogous chemical changes in other compounds. These experiments differed fundamentally from the pressure experiments of Spring and Bullock, inasmuch as in the present instance, the reactions produced are all endothermic. Energy is consumed in accomplishing them; and this energy is supplied by mechanical force. The results of subjecting a large number of chemical compounds to heavy squeezing in Mr. Lea's apparatus, which was capable of exerting a pressure of upwards of 1,000,000lb. to the square inch, were highly encouraging. The darkening of colour was in many examples well marked. The same results were subsequently repeated with greater ease by the substitution of a shearing for a compression stress on the materials. Mr. Lea's general conclusion from his experiments is that mechanical force can bring about reactions which require expenditure of energy, such energy being supplied by mechanical force in precisely the same way that light, heat, and electricity supply energy for the endothermic changes brought about by these agencies. The converse transformation—that of chemical energy into work—is, from the industrial point of view, by far the greatest chemical problem now awaiting solution. It is by no means certain that such a transformation is practically possible. At least it seems probable, says Mr. Lea, that the improvement in our method of obtaining work from the chemical energy of carbon may be in the direction of substituting electricity for heat as the intermediary.

The Sweating of Coke.—Some observations on the sweating of coke have been communicated by Mr. W. N. Page to the *Engineering and Mining Journal*, of New York. Mr. Page refers to a series of examinations made by himself over a period of ten years upon different cokes, as showing that during the hot summer months dry coke, containing not more than 1 per cent. of moisture, drawn fresh from the ovens and loaded direct into tight box trucks, without any contact with water in the yard, and in complete absence of rain, will become saturated with water when the doors of the truck are tightly closed; while if the doors are left open no such result follows. In the case of a truck so loaded with coke drawn from a beehive oven at red heat, the doors being closed, at the end of a week water would be dripping from the bottom of the truck, and the coke would average from 5 to 10 per cent. of moisture; while in a similar truck, loaded at the same time, but the doors being left open and all other conditions the same, the coke would contain less than 1 per cent. of moisture. These observations being founded upon facts, what is the explanation? It is known that dry carbon, notably fresh charcoal, possesses the peculiar quality of condensing or quietly absorbing and combining oxygen and hydrogen into water; but in the case of the wet coke, while the oxygen can be accounted for, where does the hydrogen come from? Mr. Page asks if it is possible for sufficient quantities of this gas to be contained in the cells of the coke, and be given up so slowly as to diffuse with the oxygen in a closed truck, while escaping from an open one. Though Mr. Page cannot say that sweating does not occur with coke in winter, his attention has been more particularly directed to the phenomenon during dry and hot weather. A remarkable feature observed is that the moisture contained in the coke under such conditions seems in excess of its capacity for absorbing by immersion in water, even for 24 hours. When the coke has laid in stock for some time the sweating is less apparent, or is entirely absent. Ventilation certainly prevents it. In nearly every complaint made by purchasers of their consignments of coke arriving wet, it was found that the trucks had been tightly closed during transit. One obvious deduction to be drawn by coke users is that, although coke stores should be sheltered and roofed in, they should be very thoroughly ventilated.

The Moissan Electric Furnace.—A further communication upon the artificial preparation of the diamond is, says *Nature*, contributed to the *Comptes Rendus* by M. Moissan. It was shown in an earlier memoir that when carbon is dissolved in various fused metals at the temperature of the electric furnace and at the ordinary pressure, it invariably crystallises out upon cooling in the form of graphite of density about 2; but that when the operation is performed under increased pressure the density and hardness of the carbon which eventually separates are augmented, and black diamonds are produced in considerable quantity. A modification of the original form of these pressure experiments is now described, which results in the production of small but perfectly transparent and colourless diamonds similar to those found naturally. The former experiments were made with iron and silver as solvents for the carbon, the mixture of metal and excess of charcoal being heated in the arc of the electric furnace under pressure until most of the charcoal was dissolved in the white-hot metal, after which the hot crucible was thrown into a tank of water to effect sudden cooling. Bismuth has since been tried as a solvent, but is not found suitable, as a violent explosion is caused when the fused mass is projected into water, probably owing to the sudden decomposition of a carbide of bismuth. Iron is therefore used, and the cooling is effected by pouring the contents of the crucible into a bath of just melted lead. The solution of carbon in molten iron, being lighter than liquid lead, rises to the surface in spherical globules; the smaller spheres solidify before reaching the surface of the lead, but the larger ones are still liquid, and are still so hot that they cause the lead at the surface to burn in contact with the air, incandescent particles of metal and oxide being projected out, and torrents of fumes of litharge produced. Upon removing the globules floating at the surface of the lead, dissolving their leaden coating in nitric acid, and subsequently removing the iron by suitable solvents, as previously described by M. Moissan, the transparent diamonds are readily isolated. They frequently exhibit well-defined crystal faces, which are usually curved and striated and etched with cubical markings exactly like those of natural diamonds. They possess the same wonderful limpidity, high refractive power, hardness, and density (3·5) as native diamonds, and exhibit many of the properties, such as anomalous polarisation and occasional spontaneous disruption, owing to their state of strain resulting from their formation under high pressure, which are characteristic of some Cape diamonds. The hemihedral forms of the cubic system appear to predominate in the crystals examined. They scratch rubies, and resist the action of a mixture of potassium chlorate and fuming nitric acid, but burn in oxygen at a temperature of about 900deg. with formation of pure carbon dioxide.

THE AYRTON-MATHER GALVANOMETER SHUNT.

The Paper on "A Universal Shunt Box for Galvanometers," which was read before the Institution of Electrical Engineers last week, suggests by its title that the device therein described is of universal, that is to say general, application. It might be inferred, from one or two passages in the Paper, that a shunt box of the kind described is suitable for use with almost any galvanometer, and for almost any of the purposes to which galvanometers are commonly applied. Several qualifications, however, are necessary, although the method will no doubt prove of use in a large number of cases. One of these qualifications is admitted, namely, that the current in the main circuit must be kept constant,

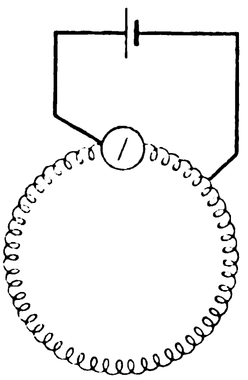

FIG. 1.

but this is not made sufficiently prominent. An ordinary shunt-box used, as is the common practice, with its own galvanometer, has a definite multiplying power, and the plug-holes are stamped $\frac{1}{10}$, $\frac{1}{100}$, &c., to denote this power; and similarly a shunt for damping a ballistic galvanometer has a definite damping constant. In neither of these respects does the Ayrton-Mather shunt-box appear to fulfil the same purpose. The illustrations, which we reproduce in our reprint of the Paper, are partly diagrammatic and partly realistic. Fig. 1 of the Paper requires a little investigation before the connections can be traced. We venture to offer the accompanying diagram to those who have no time or inclination for this investigation. Fig. 1 represents a battery, galvanometer,

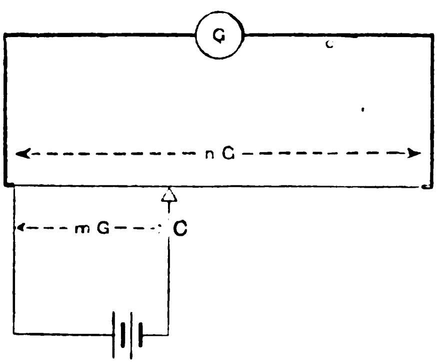

FIG. 2.

and resistance. Two circuits are offered to the current, the one through the galvanometer and one tenth of the resistance, and the other through nine-tenths of the resistance.

The simplest way of examining this method of shunting a galvanometer, is the one suggested by Mr. Crompton, and is illustrated in the accompanying figure (Fig. 2). If we have a galvanometer of any resistance, G, and we place it in series with a stretched wire resistance, n times G, and then intercept an amount m G of this wire between the battery contacts, it is easily seen that the amount of current which will go through the galvanometer will be

$$c = C\frac{m}{n+1},$$

where C is the whole current in the battery circuit. Therefore the absolute multiplying power of the shunt is

$$\frac{n+1}{m},$$

and this requires that both n and m should be known. Moreover, in order that C might be constant, some compensating resistance must generally be introduced into the battery circuit; and the value of this would vary with every different galvanometer resistance; as also would the absolute multiplying power. There is one case where a compensating resistance might be dispensed with; namely where the resistance in the battery circuit is practically infinite as compared with n G.

As Professor Ayrton has shown, the relative values of the shunts, on this system, are quite independent of the galvanometer resistance. In other words, if half the wire is intercepted between the battery contacts then half the current will pass through the galvanometer that would pass if the whole wire were intercepted. Not, be it noticed, half the *main* current. Now, operations where it is useful to know the first relation are the exception rather than the rule, for it is generally desired to find the value of the current in the main. Prof. Ayrton admits as much when he says that it is necessary to make n so large that practically the wire does not shunt the galvanometer at all when it is all intercepted between the battery contacts. Therefore the shunt n G must be practically infinite as compared with G; while, as we have just seen, the external resistances in the battery circuit must be practically infinite as compared with n G. This introduces two infinities at a stroke.

In regard to stock shunt-boxes, we are inclined to doubt that they would have any very extensive use. Apart from the fact that when using them the operator would, as a rule, be completely ignorant of their absolute multiplying power, unless special tests had been made to discover it, there are two other objections. Firstly, they could only be used with galvanometers of very low resistance; secondly, there would always be an annoying element of doubt about the limits of error in the galvanometer readings where it is desired to measure the main current.

Prof. Ayrton expressed some astonishment at the fact that this simple device was not more generally known, and that "stock" shunt-boxes were not sold by instrument makers. Supposing for a moment that the arrangement were well known, would it be to the interest of instrument makers to push it? Would they not very much prefer to go on selling specially made boxes with each galvanometer? This is a deplorably unscientific suggestion, but we are speaking of tradesmen as tradesmen, not as skilled physicists, which they happen sometimes to be.

A UNIVERSAL SHUNT BOX FOR GALVANOMETERS.*

BY W. E. AYRTON, F.R.S., AND T. MATHER.

Several years ago Mr. Latimer Clark drew attention to the fact that when shunts were used with a ballistic galvanometer in the comparison of the capacities of condensers, the results were inaccurate if the multiplying powers of the shunts were assumed to be the same as those employed with steady currents; shortly afterwards the matter was investigated mathematically by the late Mr. Hockin, and he showed that the inaccuracy was caused by the change which the application of the shunt produced in the damping of the swing of the ballistic galvanometer. Hence the instantaneous deflection of a galvanometer when shunted showed an extra diminution, as if its resistance had been increased by an amount which depended on the details of the construction of the particular galvanometer, and on the adjustment of the controlling magnet.

In 1892, when giving a preliminary account of our "workshop ballistic galvanometers" at the Physical Society, we incidentally mentioned a method that we had devised of constructing shunts which entirely overcame this difficulty. At that time we had only perceived that our method of constructing *constant-damping* shunts was of value in connection with ballistic galvanometers; but subsequently it occurred to us, when specifying the resistance of such constant-damping shunts, that this method of construction not only removed the difficulty which had been pointed out by

* A Paper read before the Institution of Electrical Engineers.

Digitized by Google

Mr. Latimer Clark in connection with ballistic galvanometers, but it enabled the same shunt box to be used with any number of different galvanometers of any resistance and of any type, and with an accuracy in the measurement far greater than could be obtained with the ordinary form of shunt box which had been specially constructed for the particular galvanometer.

As this method of making shunt boxes has not yet been published, and as it possesses important advantages of which we were not aware when we alluded to it at the Physical Society, we have thought that a short description of the method may interest the members of the Institution of Electrical Engineers.

To appreciate its advantages let us first consider the common, well-known method of constructing shunts, and the defects it possesses.

1. The resistances of the 1-10th, 1-100th, and 1-1,000th shunt must have exactly 1-9th, 1-99th, and 1-999th of the resistance of the galvanometer; therefore, if the resistance of the galvanometer be 1,000 ohms, for example, the shunts must have 111·1, 11·11, and 1·111 ohms resistance; hence we must construct the 1-1,000th shunt accurately to the 1-1,000th of an ohm if we wish it to be correct to even 1-10th per cent.

2. But the galvanometer is wound with copper wire; we are, therefore, at once met with the difficulty as to what wire we ought to employ in winding the shunts. If we use German silver, platinoid, manganin, or any substance of low temperature coefficient for the wires of the shunt coils, their resistances may be quite constant, but a rise of 10°C. in the temperature of both the shunts and of the galvanometer will make an error of 4 per cent. in the resistance of the former relatively to that of the latter.

If, on the other hand, we wind the shunts with copper wire, then, since the shunts are not inside the galvanometer case, it is very difficult to ensure, from the readings of thermometers, that there is not a difference of some two or three degrees between the mean temperatures of the shunt box and of the galvanometer, so that the resistances of the shunts may easily be 1 per cent. wrong relatively to that of the galvanometer.

In fact, except in the rare case when the galvanometer as well as the shunts are wound with German silver, manganin, or other wire of low temperature coefficient, it is useless spending time making accurate adjustments of the resistances of the shunt coils as ordinarily constructed.

3. Even if the resistances of the shunts be exactly 1-9th, 1-99th, and 1-999th of the galvanometer, they act as if they did not allow 1-10th, 1-100th, and 1-1000th respectively of the charge in a condenser to pass through the galvanometer when used ballistically.

4. Lastly, for each galvanometer there is needed a separate set of shunts.

All these defects arise from the fact that the method hitherto adopted of varying the current through a galvanometer while the current in the main circuit remained the same, has consisted in varying the resistance of the shunt to the galvanometer. If, however, we leave the shunt to the galvanometer untouched, and, instead, vary the current through the galvanometer by varying the point of attachment of the main leads, we remove all these difficulties at once.

A shunt box constructed in this latter way is seen in Fig, 1. The terminals A and B of the shunt box are permanently connected respectively with the terminals of the galvanometer G, while the terminals B and C of the box are connected with the two main wires which lead the current up to, and away from, the galvanometer and shunt. The ends of a coil of *any* resistance r ohms are permanently connected as shown, and at points in this coil corresponding with $\frac{r}{10}, \frac{r}{100}, \frac{r}{1,000}$ ohms permanent connections are made with the various blocks of the shunt box as illustrated.

Then, whatever be the resistance of this coil r, compared with the resistance of the galvanometer g (either, or both, of which may therefore be unknown), it is easy to show that if G amperes be the current flowing round the galvanometer when a plug is placed into the hole marked d, it will be $\frac{G}{10}, \frac{G}{100}$, and $\frac{G}{1,000}$ amperes respectively when the plug is put instead into the holes marked c, b and a respectively, provided that the current in the main circuit remains constant—the condition which is, of course, assumed to be true in the ordinary use of shunts. Or, if a definite quantity of electricity flow into or out of a condenser in the main circuit, and Q coulombs be the quantity of electricity that flows round the galvanometer when the plug is in the hole marked d, $\frac{Q}{10}, \frac{Q}{100}$, and $\frac{Q}{1,000}$ coulombs will be quantities that flow round the galvanometer when the plug is put into the holes c, b, and a respectively, and the deflections will correspond with these quantities.

For let the constant current in the main circuit be called A: then, when plug is in hole d, the galvanometer current equals

$$\frac{r}{r+g}\text{ A, say G};$$

when plug is in hole c, the galvanometer current equals

$$\frac{\frac{r}{10}}{\frac{r}{10}+\left(\frac{9}{10}r+g\right)}\text{ A, or }\frac{G}{10};$$

when plug is in hole b, the galvanometer current equals

$$\frac{\frac{r}{100}}{\frac{r}{100}+\left(\frac{99}{100}r+g\right)}\text{ A, or }\frac{G}{100};$$

when plug is in hole a the galvanometer current equals

$$\frac{\frac{r}{1,000}}{\frac{r}{1,000}+\left(\frac{999}{1,000}r+g\right)}\text{ A, or }\frac{G}{1,000}.$$

Similarly, if K be the number of coulombs flowing into, or out of, a condenser in the main circuit, and pK or Q be the number of coulombs that flow round the galvanometer when the plug is put into the hole marked d, it may be proved that, *since the resistance of the galvanometer plus that of the shunt is constant, and therefore the damping is constant*, the quantities of electricity will flow round the galvanometer when the plug is put instead into the holes marked c, b, a, respectively are $\frac{Q}{10}, \frac{Q}{100}, \frac{Q}{1,000}$ coulombs.

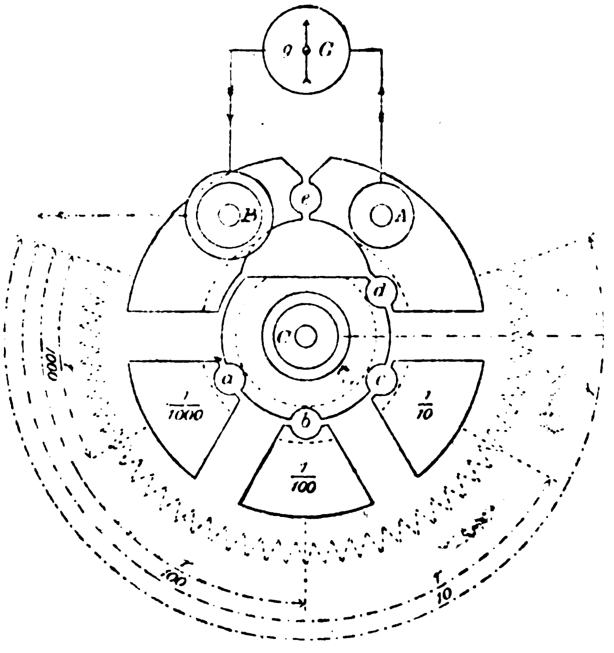

FIG. 1.

Hence the galvanometer may be wound with copper or with any other wire; a single set of shunts may be made of manganin wire, and be accurately subdivided into *exact* numbers of ohms, *fractions of an ohm being unnecessary with our system*; the galvanometer may have any resistance and be at any temperature, provided it is constant while a set of tests is being made—then the sub-division of a steady current or the sub-division of an instantaneous rush of electricity into parts having the ratios of $1, \frac{1}{10}, \frac{1}{100}, \frac{1}{1,000}$, is effected with *great accuracy*.

Stock shunt boxes, ready wound for use with any galvanometer, in the measurement of steady currents or of instantaneous rushes of electricity, are exhibited on the table.

The arrangement of shunt box illustrated in Fig. 1 may be regarded as possessing one defect—viz., that the whole current flowing in the mains cannot be sent round the galvanometer without disconnecting the main wire from the terminal C, and connecting it instead with the terminal A. To save the trouble of having to do this, and to enable every combination to be made by simply shifting the plugs, we sometimes construct the blocks of the shunt box as seen in Fig. 2. When one plug is placed and

Digitized by Google

left in the hole marked *h*, and a second plug is placed in one or other of the holes marked *d*, *c*, *b*, or *a*, we obtain exactly the results already described in connection with the box seen in Fig. 1. Placing, however, one plug only in the hole marked *f*, the entire current flowing in the mains circulates round the galvanometer. If a plug be placed in the hole *f*, and another in the hole *j*, the galvanometer is short-circuited—a result obtained by placing the two plugs in the holes marked *d* and *e* in Fig. 1. The arrangement shown in Fig. 2 has the further advantage that it is possible, by putting a single plug into the hole marked *j*, to disconnect one terminal of the galvanometer from the circuit without breaking the circuit. This method of connecting is convenient to employ when taking the zero with a very sensitive galvanometer, for in that case it may happen that, although the galvanometer is apparently short-circuited through a very low resistance, enough of the main current, although but an extremely small fraction, passes round the galvanometer to produce a small deflection.

When, however, *r* is more than about ten times as great as *g*, the simpler form of shunt box illustrated in Fig. 1 is sufficient for ordinary purposes; for, although by merely shifting the plug with this type of box, it is impossible to send a greater current round the galvanometer than $\frac{r}{r+g}$ A amperes, where A is the current in the mains, this value of G, being more than $\frac{10}{11}$ A, is sufficiently near A for ordinary purposes.

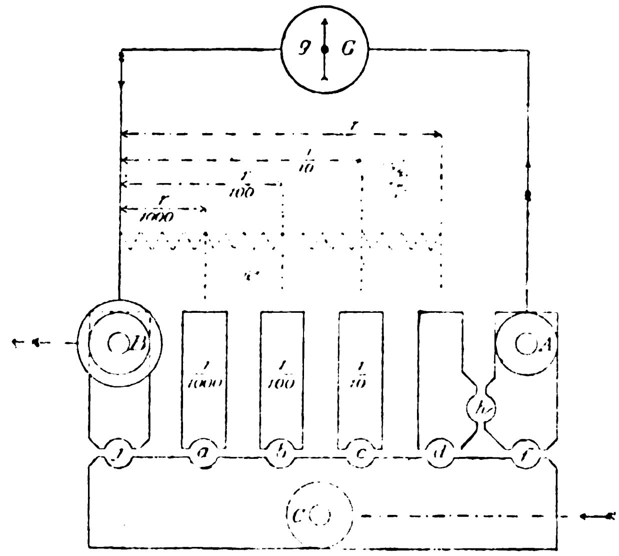

Fig. 2.

Of course, whatever be the value of *r*, whether large or small compared with that of *g*, the current that flows round the galvanometer when the plug is put into the poles marked *c*, *b*, and *a* respectively, is exactly 1-10th, 1-100th, and 1-1,000th of its value when put into the hole marked *d*. The only advantage that is gained by making *r* large compared with *g* is that $\frac{r}{r+g}$ A, or G, the unit current, becomes then practically equal to A.

The method of using shunts above described has, then, the advantage that it enables the same shunt box to be used with any galvanometer of any resistance, whether ballistic or not; but it does more than that, for a consideration of our method of varying the point of attachment of one of the mains, instead of varying the resistance of the shunt itself, shows that *any ordinary* resistance box can be employed as a shunt with *any* galvanometer, and the fractions of the current that pass round the galvanometer and through the shunt respectively can be read off at once, *without any calculation and without a knowledge of the resistance of the galvanometer*, to a far higher degree of accuracy than is possible with a set of shunts specially constructed for the particular galvanometer in the ordinary way.

By employing this device we also find that great simplification and cheapening of cost is effected in the employment of a d'Arsonval galvanometer with shunts of platinoid or manganin sheet for the measurement of electric currents over a wide range.

ADDENDUM, received April 2, 1894.

It is well known that with the ordinary method of constructing shunts the resistance of the circuit is altered when the shunt is varied. An interesting question, therefore, arises whether this change in the resistance of the circuit is greater with the method that we have proposed of constructing a shunt or with the ordinary method.

With the ordinary method of keeping the main leads M_1, M_2 (Fig. 3) permanently connected with the galvanometer G, and of varying the current through the galvanometer by altering the resistance, *s*, of the shunt, the change that is produced the in resistance of the circuit on applying this shunt is, as well known, *from* g to $\frac{sg}{s+g}$, that is, the resistance is diminished *by* $\frac{g^2}{s+g}$. If then the shunt be such as to allow $\frac{1}{n}$th of the current to pass through the galvanometer s equals $\frac{g}{n-1}$, and the resistance in circuit is diminished by $\frac{n-1}{n} \times g$ when this hunt s applied. For example, if n be 10, the resistance of the circuit will be diminished by $\frac{9}{10}$th of g.

With our proposed method of keeping a *fixed* resistance r attached to the galvanometer G (Fig. 4), and of varying the current through the galvanometer by varying the connection of one of the main wires, for example by moving the main wire M_2 from the point d to the point c, the resistance of the circuit is altered *from* $\frac{rg}{r+g}$ to $\frac{\frac{r}{n}\left(\frac{n-1}{n}r+g\right)}{r+g}$ that is the resistance in the circuit is diminished *by* $\frac{1}{r+g}\left\{\frac{n-1}{n}\cdot rg - \frac{n-1}{n^2}r^2\right\}$ . . . . (1)

Now this expression depends not merely on the values of n and g, but also on the value of r. If r is selected so as to be less than ng the expression (1) is positive, that is the resistance of the circuit is *lessened* by shifting the main M_2 from the point d to the point c; whereas, if r is selected so as to be greater than ng the expression (1) is negative, which means that shifting the main M_2 *increases* the resistance of the circuit. Lastly, if r be chosen so as to be exactly equal to ng, shifting the main produces *no change whatever* in the resistance of the circuit, so that the current *now* passing through the galvanometer after shifting M_2 is exactly $\frac{1}{n}$th of the current that *previously* passed through the galvanometer, for the current in the main circuit undergoes no change whether the resistance of the circuit be large or small.

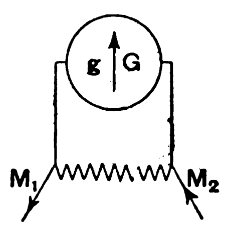

Fig. 3.

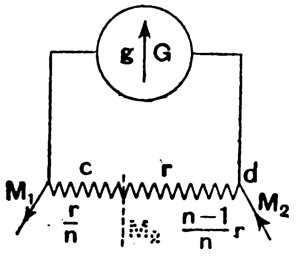

Fig. 4.

By selecting r, then, so that it is roughly equal to ng, our proposed arrangement gives the following result on shifting the main M_2 from d to c:—

(*a*) If the resistance of the rest of the circuit be large compared with that of the galvanometer, the current that now passes through the galvanometer is exactly $\frac{1}{n}$th of that which *previously* passed, whatever be the temperature.

(*b*) If the resistance of the rest of the circuit be even small compared with that of the galvanometer, the current that now passes through the galvanometer is very nearly $\frac{1}{n}$th of that which *previously* passed, whatever be the temperature.

Contrasted with this we have, with the ordinary method of applying a shunt, the result:—

(*a*) Even if the resistance of the rest of the circuit be large compared with that of the galvanometer, it is only when the temperature has one definite value that the current that now passes through the galvanometer is exactly $\frac{1}{n}$th of the current that *previously* passed.

(*b*) If the resistance of the rest of the circuit be small compared with that of the galvanometer, the current that *now* passes through the galvanometer is far greater than $\frac{1}{n}$th of the current that *previously* passed.

Lastly, whatever be the values of g, r, and n our method of altering the current through the galvanometer produces less change in the resistance of the circuit than the ordinary method. For, as already seen, with the ordinary method of applying a shunt the resistance of the circuit is diminished by $\frac{n-1}{n}g$, while on moving the main M, from d to c with our method the resistance of the circuit is diminished by

$$\frac{1}{r+g}\left(\frac{n-1}{n}rg - \frac{n-1}{n^2}r^2\right);$$

therefore the ordinary diminution of resistance, minus the diminution of resistance in our case, equals the difference between these expressions, which is

$$\frac{(n-1)(ng^2+r^2)}{n^2(r+g)} \quad . \; . \; . \; . \; . \; . \; . \; . \quad (2)$$

Now this expression (2) is always positive, when n is greater than unity, therefore our method of shunting produces the *less* change in the resistance of the circuit in all cases.

DISCUSSION.

Speakers who have returned their proofs revised have their remarks prefaced by an asterisk.

Mr. HIGGINS sent a communication, which was read by the Secretary, in which was enclosed a drawing of a form of apparatus which he said he had used in exactly the same manner and for the same purpose for the past twenty years.

Mr. MORDEY said he had not, perhaps, followed Prof. Ayrton's description closely, and there might be others in the same difficulty. There were two points he would like to have made clear. Apparently, if the connection at one point were altered the resistance of the whole circuit was altered. The other point was whether the relative resistance of the shunt and the galvanometer did not matter.

Mr. CROMPTON said rather a simpler method was to use a graduated wire and shunt it, when they got into the potentiometer method at once.

*Prof. AYRTON said the graduated wire would not do at all when they were dealing with a galvanometer with a resistance of some thousand ohms, for they wanted the greater part of the current coming along the main to go through the galvanometer, and that would not be the case unless they had their graduated wire resistance large compared with that of the galvanometer. There was no doubt, of course, that every resistance box was a graduated wire, and they might say whenever they used a resistance box that they used a graduated wire, but that was not using a graduated wire in the ordinary sense. Mr. Higgins said he had used the principle of the method for twenty years. He could only say if Mr. Higgins had announced, when Mr. Latimer Clark's and Mr. Hockin's Papers were read, "Here is a method which gets over your difficulty, and which renders the mathematics of Mr. Hockin unnecessary," he would have conferred a very great benefit on electricians, for certainly they had not until recently seen how they could arrange a system of shunts so that for ballistic purposes the ratios would be exactly the same as they were for direct currents, and certainly they had not seen that it was possible to make stock shunt boxes do for any galvanometer. If they had, then why did the instrument makers not construct them? So far from the method of making a universal shunt box being previously recognised, why, even Mr. Mordey had not yet appreciated the principle that the resistances of the shunts might have any value if they were only properly related to one another, because, he asked, why was it not necessary to make those resistances of particular values relatively to the resistance of the galvanometer. With regard to the point spoken of by Mr. Mordey, that if they altered the shunt connection they altered the resistance in the main circuit, that, of course, was an objection to all ordinary shunts. If they changed the shunt in an ordinary box they altered the resistance in the main circuit, and therefore they altered the current, unless they were dealing with very high resistances in the main circuits, testing the insulation of a cable or a condenser, or something of that kind. He had put in the proviso, "provided that the current in the main circuit remains constant," a condition which was assumed to be true in the ordinary use of shunts. With regard to Mr. Mordey's other point, the proof was given in the Paper, on slip 2. It made no difference what were the values of r and of q so long as they had fixed values for the time they were making the experiment. Whatever the resistance of the box or galvanometer, provided they remained constant, say for ten minutes, it did not matter what r was. They had also exactly the same relationship if they were measuring the capacities of condensers or submarine cables; they had exactly the same proportion, and might use exactly the same shunt boxes, without employing the correction which Mr. Hockin showed was necessary in the ordinary employment of shunts.

French Electric Coast Lights.—The Trinity yacht "Irene" has just returned from a visit to the French coast. The visit was made by a Committee of Trinity House with a view of obtaining full information respecting "*les feux éclairs.*" The Committee inspected the lighthouse of La Hève, on the extreme point of the northern bank of the estuary of the Seine, from which a light of the new type had been shown for some months. It was also desired to observe the system of gas-lighted buoys, by means of which the French authorities hope to avoid the necessity of maintaining costly lightships in certain positions. The Committee consisted of Captain G. R. Vyvyan, Admiral Sir Leopold M'Clintock, and Captain Slader, elder brethren of the Trinity House, who were accompanied by Mr. Charles A. Kent, the secretary, and Mr. Thomas Matthews, the engineer to the Corporation. At Havre the Committee were met by M. Bourdelles, the Inspector-General, M. Guirand, engineer for the Seine District, MM. Ribière and Vetillart, also engineers of the Lighthouse Department of the Ministry of Public Works, and by them were received with the greatest courtesy and good will. The party visited the lighthouse at La Hève, where the whole of the system was fully explained in detail, the quick flashes of the light being shown to be produced by rapid rotation of the lenses. The Committee subsequently, when crossing the Channel, made some comparisons of the quick flashes of La Hève lights with the slower characteristics of the St. Catherine's electric light.

ON CATHODE RAYS IN GASES UNDER ATMOSPHERIC PRESSURE AND IN EXTREME VACUA.*

BY PHILIPP LENARD.

(*Concluded from page 616.*)

17. Gases are less illuminated by the cathode rays the more they are attenuated. In measuring the radiation lengths in air and hydrogen the following was noticed:—The luminosity of the two gases at atmospheric pressure described above (3, 15) quickly loses in brightness and gains in extent as exhaustion proceeds, as might be expected from our conception of this luminosity as a consequence of the absorption of the rays in the gas. The lengths of the illuminated tracts are not to be exactly indicated, since the luminosity, faint in itself, always decreases gradually from the window, but they were comparable with the radiation lengths (Table III.). While the luminosity of the gases diminishes, the glass phosphorescence of the tube increases; already at 50mm. pressure, both in air and hydrogen, the glow is imperceptible in presence of the phosphorescence. The interior of the tube now appears dark, and remains so until the pressure has fallen to about 2mm. At this exhaustion the gases recommence to glow much brighter than before, and in a very different manner. The light no longer proceeds from the window, but from the two metallic clamps holding the observation tube. At first in their neighbourhood, and then after further exhaustion, along its whole length the tube is filled with a reddish (sometimes I find "bluish" noted) and fairly bright column of light. Conductors in the neighbourhood of the tube have some influence upon the distribution of this light. If the tube is, for instance, grasped in the hand in one place, the column of light usually ends at that point, and the remainder of the tube remains dark. This was utilised in the previous and also in the subsequent experiments (16, 18, 20), when the screen during observation had to be protected from extraneous light; the phosphorescence at the screen or the glass wall is not affected by the hand or other conductors. This light remains down to very small pressures: that it again disappears in extreme vacua has already been noticed above (12, 13). The glowing of the gas has no close connection with the cathode rays. For, on the one hand, it is not necessarily extinguished,† when the cathode rays are intercepted from the observing space, be it by moving the screen towards the window, or by a magnet near the discharge tube. On the other hand, the light column disappears always and completely when the observing tube is surrounded along its entire length by wire gauze, touching the window wall and the metal cap at the other end. The phosphorescence of the glass wall and the screen, as well as the luminosity of the window are, however, retained in the gauze envelope, as also the magnetic deflection of the rays picked out by a diaphragm (*see* 18 below). The gas, under low pressure is not, therefore, illuminated by the cathode rays, but by the same electric forces, due to the generating apparatus, which produced the small sparks (10) under ordinary pressures in the observing space. Thus the light column also appears when cathode rays are produced in an altogether different vacuum tube in the neighbourhood. That the first mentioned glowing of the gas, attributable to irradiation by the rays, persists after the exclusion of the electric forces, had already been shown before (10), at least for air at ordinary pressures.

In other gases also (*see* 18 below) essentially similar phenomena were observed, as in air and hydrogen.

The negative glow light in Geissler tubes is also to be regarded as gas illuminated by cathode rays.‡ Between that phenomenon and the glow observed here and attributed to irradiation there exists a correspondence, inasmuch as in both cases the light disappears at high exhaustions, appears fainter and larger when the pressure increases, and then becomes brighter and smaller. But whereas the glow in the Geissler tube has already become very bright and small at 0·5mm. pressure, the gas in our experiments remains much darker up to 760mm. pressure, and yet the illuminated space is much larger. This difference cannot, therefore, be attributed to an inferior intensity of the rays here used. But it will be explained as soon as we can show that at higher pressures cathode rays of a different kind are produced, which are much more strongly absorbed by gases than the rays investigated hitherto and produced at very low pressures.

18. Different gases are turbid media to very different degrees. With greater permeability we invariably find associated greater clearness. To study the manner of propagation of the cathode rays in different gaseous media we observe the course of pencils of rays separated out by a diaphragm, and traced in phosphorescent

* *Wiedemann's Annalen.*

† Sometimes it is. The cathode rays appear to support the formation of the light column. This may be connected with the fact that the cathode rays make the observing space conducting (11).

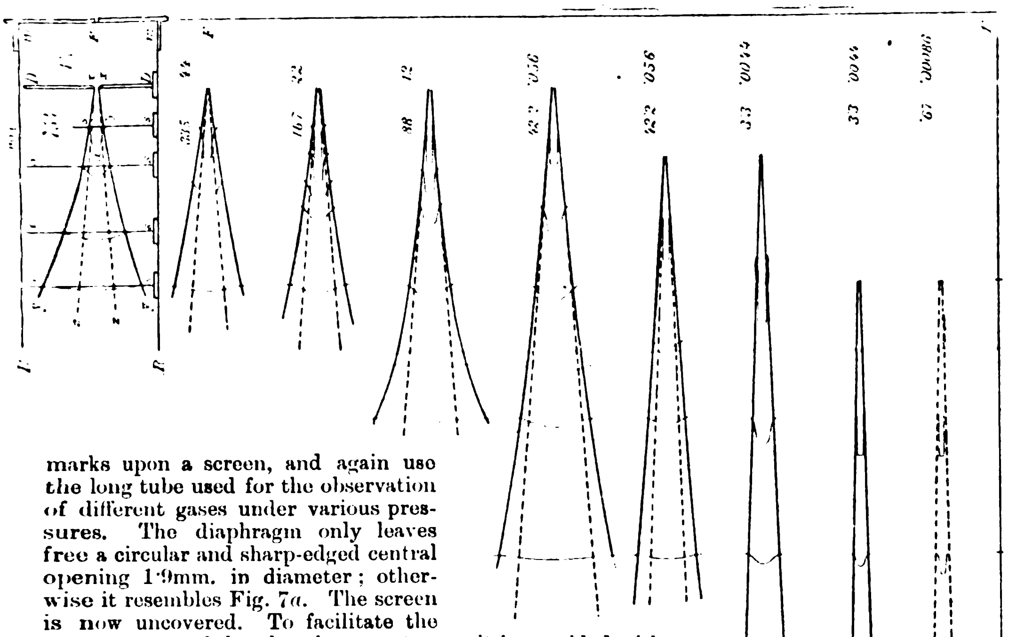

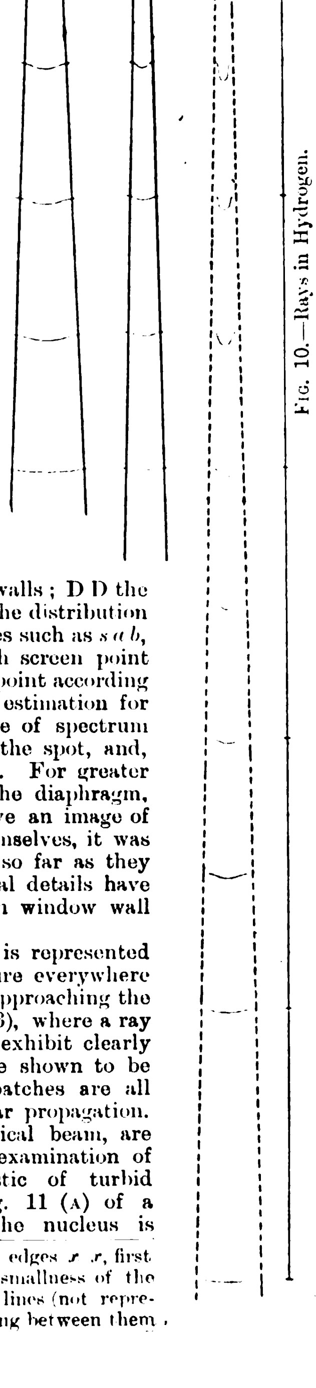

Fig. 10.—Rays in Hydrogen.

marks upon a screen, and again use the long tube used for the observation of different gases under various pressures. The diaphragm only leaves free a circular and sharp-edged central opening 1·9mm. in diameter; otherwise it resembles Fig. 7*a*. The screen is now uncovered. To facilitate the measurement of the phosphorescent spots it is provided with black paper strips (Fig. 9*b*) of measured sizes and distances on the side away from the window, from which it is observed. If the spot falls upon this scale in a manner unfavourable for measurement, it is displaced by approaching a magnet. This also offers the opportunity of making sure that all the rays observed are deflected in the manner characteristic of

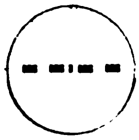

Fig. 9b. (Half Size.)

cathode rays. The ray passing through the diaphragm does not mark its course in the gas except at high pressures, as might be expected from the previous results; the glass wall also remains dark behind the diaphragm, only in front of it, up to the window, it glows green.

What was observed on the phosphorescent screen cannot be better exhibited than as graphically represented in Fig. 10. Each representation, such as Fig. 10, No. 1, is intended as a section through the axis of the rays and the observation tube. *m m* is the window wall with the window F; *m* R are the tube walls; D D the diaphragm; *s s* is in each case a tested position of the screen. The distribution of brightness in the phosphorescent spots is shown by small curves such as *s a b*, drawn in such a manner that the horizontal distance from each screen point to the curve gives the brightness of phosphorescence of that point according to an arbitrary scale, which is kept as uniform as possible by estimation for all the figures. The representation is that usual in the case of spectrum lines; it gives the distribution of light along a diameter of the spot, and, by rotation round the axis of the beam, over the whole spot. For greater clearness all the spots of a beam, together with the hole in the diaphragm, are joined by the horizontal curves, *x y*, which, therefore, give an image of the beam, although in most cases, as shown by the spots themselves, it was certainly not sharply defined. The beams are always drawn so far as they continued to give any well-marked spots at all. All unessential details have been omitted from the beams. F F always means the common window wall of different beams to be compared.

Let us now study the rays in hydrogen (Fig. 10). In No. 1 is represented a beam in hydrogen at ordinary pressure (compare the pressure everywhere indicated). It is fairly straight, the propagation much more approaching the rectilinear than in air of equal pressure (compare 8 and Fig. 3), where a ray proper never existed. This ray is, however, definite enough to exhibit clearly the deflection by a magnet. And yet hydrogen, which will be shown to be the clearest gas, is rather turbid, for the phosphorescent patches are all much larger than they could possibly be in the case of rectilinear propagation. The extreme limits of rectilinear propagation, of the geometrical beam, are given by the dotted line *x z*.* We further notice, on closer examination of the first phosphorescent spot another property characteristic of turbid media. This spot consists, as shown by the curve and Fig. 11 (A) of a very bright nucleus surrounded by a less bright halo. The nucleus is not yet sharply marked off from the halo, but still distinctly enough. Such a phenomenon is never witnessed in the case of rectilinear propagation. It is neither seen in cathode rays in a perfect vacuum in any position of the diaphragm or the screen, nor is it shown in the case of light. If we replace the window by an equally large illuminated aperture, the phosphorescent screen by a paper screen, we obtain with the same diaphragm under all circumstances nothing but more or less sharply-defined spots, in which we never find a nucleus distinct from a halo. The introduction of a glass trough with dilute milk between the window and the diaphragm, or between the latter and the screen, at once gives nuclei and halos. The nuclei are equal in size to the patches of light without milk, and therefore correspond to rectilinear rays, whilst the halos represent diffused rays. To complete the correspondence, the milk must in this experiment be diluted so far that besides diffused luminosity one can just perceive sharp images of bright objects through the trough. In the case of cathode rays in hydrogen, also, the nucleus of the phosphorescent patch is of the size corresponding to rectilinear propagation, only the halo overlaps beyond the geometrical shadow (*x z*). The diffused rays here only make up a small fraction of the total rays, for the halo is feeble in comparison with the nucleus. But if we now displace the phosphorescent screen further from the window we see that the nucleus becomes darker, the halo lighter, so that soon the limit between the two vanishes (compare the second patch in Fig. 10, No. 1); the nucleus is, so to speak, devoured by the halo. As the path through the turbid medium becomes longer, more and more rays are deflected from the straight path, and turned through larger and larger angles. Owing to this increasing diffusion the ray expands more and more (*see* the further phosphorescence patches), the limits of the patches become very ill-defined, and the screen appears almost uniformly illuminated.

On reducing the pressure down to 335mm (No. 2) a change at once takes place; all the patches become narrower, sharper, and brighter; all signs of increasing limpidity. The nucleus of the first patch is now separated very sharply and strikingly from the delicate halo, as seen in Fig. 7 (B). On further diminishing the pressure, down to 167mm. (No. 3), the halo round the first spot almost entirely disappears. In this figure it is specially well seen how, on displacing the screen, the halo is extended and increases in brightness at the expense of the nucleus. The beam is perceptible, but not very well, and is broader than the geometrical beam. Its front portion is even more contracted in the following diagram (No. 4), at 88mm. pressure. Here, for the first time, we meet with a sharp spot without any halo*, so that in hydrogen of 88mm. pressure no diffusion is observable along the path

* These lines would, therefore, if produced beyond the diaphragm edges *x x*, first intersect and then fall upon the frame of the window. Owing to the smallness of the scale they are not put in by construction, but by calculation. The lines (not represented) which join the window and the diaphragm without intersecting between them would run nearly parallel.

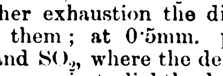
* Such spots might, doubtless, have been produced at higher pressures if it had been possible to approach the screen further than 1·5 cm. to the diaphragm; this was prevented by the iron feet.

Digitized by Google

of 4cm. between the window and the screen; only at greater distances it becomes evident from halos, and then by a fan-like expansion of the beam. Hydrogen becomes even more limpid at 42mm. pressure (No. 5). Nuclei in the patches are now seen at greater distances from the window. The great breadth of the beam now only seems conditioned by small distance between diaphragm and window. If we now increase this distance from 2·5 to 5 cm. (No. 6) without changing the pressure, the ray becomes, in fact, correspondingly narrower. On exhausting further to 3mm. (No. 7), the beam does not perceptibly differ from the geometrical beam; the dotted lines in the figure coincide with the continuous ones, and are, therefore, invisible; the patches hardly show halos. If, in order further to test the rectilinear propagation, we increase the distance between window and diaphragm to 10cm. (No. 8), the ray becomes narrower in the same proportion as the geometrical one; the phosphorescent patches change in the same manner as would light patches under equal conditions. Finally, at 0·67mm. pressure, the increased transparency is the only thing noticed; the ray has increased in length, and the patches in brightness. On closer inspection it is seen, however, that all the spots are now somewhat smaller than would correspond to rectilinear propagation, as was seen in the perfect vacuum and in the case of light (13). The coincidence of the two previous beams (at 3mm., Nos. 7 and 8), with the geometrical beams must, therefore, be taken as a slight indication of residual turbidity.

In the other gases also turbidity is shown in the same way as in the case of hydrogen, by the extension of the rays and by halos. All gases become more limpid as exhaustion increases. Compared with the others at equal pressures hydrogen appears far and away the most limpid gas; nitrogen, air, and oxygen are about equally turbid; carbonic acid is more so, and sulphurous acid most of all. The denser gas, therefore, is always more turbid than the less dense; to large differences in density correspond large differences of turbidity, and *vice versâ*. It is evident that turbidity and absorption (15, 16) are inseparable.

At 180mm. pressure only hydrogen allows the formation of a regular beam. For the investigation of such turbid media as are the other gases in this case, the apparatus used was not suitable, inasmuch as the screen could not be brought close enough to the



A. B.

Fig. 11.

diaphragm; hence there is no very distinct difference noticeable between N_2, O_2, and CO_2; SO_2 alone appears perceptibly more turbid. At 40mm. pressure all gases have become clearer, the differences are more pronounced. CO_2 now is decidedly more turbid than O_2, SO_2 even more so. The differences are most decided at 10mm. pressure, where O_2 is distinctly more turbid than N_2. Upon further exhaustion the differences between the gases disappear with them; at 0·5mm. pressure, turbidity is only noticed at CO_2 and SO_2, where the delicate halos of the first phosphorescent patches project slightly beyond the geometrical beam, with which otherwise the cathode ray coincides.

All the observations not graphically reproduced confirm what has been said. In particular the rays in air are only slightly or not at all different from those in oxygen and nitrogen of equal pressure, as might be expected from the slight difference between the two last. A list of all rays fully observed and drawn is found in Table IV.; the positions of the diaphragm chosen were the most characteristic. When the diaphragm is placed close to the window the rays lose in definition, if only in consequence of the geometrical conditions; when it is further removed they lose in intensity and length in consequence of absorption. The essential differences, however, between the various media are always perceptible, though perhaps less distinct. All the gases were carefully prepared, washed, and dried. During the change from one gas to the next the observing space was emptied, filled with the new gas, again exhausted, and refilled. H_2 and CO_2 were derived directly from the producing apparatus, O_2 and N_2 from a gas-holder, SO_2 from the bottom of a very large and comparatively narrow glass cylinder out of which it had displaced air by gravity.

That the extension of the beam behind the diaphragm is in reality essentially limited to the space which we have described as the ray, and represented as such in the figures, could be proved by the interposition of the partition Fig. 9, between the diaphragm and the screen. The phosphorescent patches are in this case only changed (darkened at the edge) when the partition overlaps into the space described as the ray. Introduced between the window and the diaphragm the partition has no influence upon the phosphorescent spots. Such experiments were performed in air at various pressures.

19. The turbidity is only determined by the density of the gaseous medium. Different gases become equally turbid when they are brought to equal densities by variations of pressure. During the comparison of rays in various gases it appeared surprising that no single gas exhibited any specially characteristic property. Different gases behaved no more differently than the same gas at different pressures. If this applies all through, we must be able to find for any gas a pressure at which the propagation in it is exactly the same as in any other gas at a given pressure. Supposing we attenuate sulphurous acid, for instance, sufficiently, it must give exactly the same ray as hydrogen at ordinary pressure. Generally, all the rays observed must allow themselves to be ranged in a single series, from the most turbid gas to the clearest, as if they were all of them observed in one and the same gas, only at different pressures. This is, in fact, perfectly feasible. To compare easily and accurately any two rays I had copied each of them on to a strip of squared paper, and these strips were without difficulty arranged as required, so that all equally situated phosphorescent patches were smaller and sharper in each succeeding ray as compared with the preceding. Only I obtained, of course, three series instead of one, corresponding to the three positions of the diaphragm, since only such rays were comparable as were obtained with equal positions of the diaphragm. The following are the three series, always beginning with the most turbid medium (Table IV.)

Table IV.

1.—Diaphragm 2·5 cm. from the window.

Gas.	Pressure. mm.	Density. H_2 760mm. =1.
Air	385·0	7·3
SO_2	180·0	7·6
CO_2	180·0	5·2
O_2	180·0	3·8
N_2	180·0	3·3
SO_2	86·0	3·6
SO_2	42·0	1·8
CO_2	39·2	1·2
H_2	754·0	1·0
O_2	40·0	0·87
N_2	41·6	0·78
Air	40·0	0·76
H_2	335·0	0·14
SO_2	9·0	0·38
CO_2	10·2	0·30
H_2	167·0	0·22
Air	10·2	0·19
H_2	88·0	0·12
H_2	42·2	0·056

2.—Diaphragm 5cm. from the window.

Gas.	Pressure. mm.	Density. H_2 760mm. =1.
SO_2	3·8	0·16
CO_2	3·2	0·093
O_2	3·3	0·070
H_2	42·2	0·056
Air.........	2·9	0·055
N_2	3·0	0·055
H_2	3·3	0·0044

3.—Diaphragm 10cm. from the window.

Gas.	Pressure. mm.	Density. H_2 760mm. =1.
CO_2	0·50	0·015
SO_2	0·50	0·021
H_2	3·3	0·0044
O_2	0·65	0·014
N_2	0·45	0·0085
H_2	0·67	0·00086

It will be seen that the media thus arranged according to decreasing turbidity are also arranged according to decreasing density. Sporadic divergences only occur in the densest media, where the method of investigation makes the rays appear almost equal, and in the most attenuated, where the turbidity and the differences vanish together. The only property of any gaseous medium determining the turbidity is, therefore, its density; in other words, equal masses always bring about equal disturbance.

20. Cathode rays of various kinds are diffused to different extents. Up to the present we have always kept the conditions of production as constant as possible (15), and have only investigated cathode rays of a single definite kind. Thus especially the pressure in the discharge tube in the preceding radiation experiments was always such that sparks passed occasionally between the spheres, B (Fig. 1), kept at 2·8cm. distance. If we now diminish the pressure in the discharge-tube while the medium in the observing space remains the same, we have in the first place to expect an increased intensity of the rays (2), and a brightening of the phosphorescent spots. If their diameter increases at the same time this need not create surprise if we remember their blurred edges; the enlarging could only be apparent. But the reverse happens. While the brightness of the patches increases strongly at the centre, it diminishes at the edges, the patches contract in circumference, and become distinctly sharper. But on increasing the gas pressure in the discharge tube the spots not only become darker, but larger and more blurred; if nucleus and halo could be distinguished these may be completely fused. These appearances were often noticed when, during the preceding experiments (18) the vacuum in the discharge tube was brought to the correct amount. With special attention I have followed it in air of 13mm. pressure in hydrogen at 167mm., and carbonic acid at 39·2mm.,

Digitized by Google

when the length of spark measuring the exhaustion of the discharge tube was varied between 2 and 4 cm.

I conclude that cathode rays produced at different pressures possess the property of diffuse propagation in gases to a different extent. Rays produced at lesser exhaustions are more diffused than those produced at greater exhaustions. That there are different kinds of cathode rays, the properties of which blend into each other in a manner corresponding to the colours of light, and which differ in their capacity of phosphorescence, absorption, and deflection by a magnet, has already been remarked by Hertz.* As in the case of the diffusion and propagation of cathode rays in gases generally, so the phenomenon observed here has its well-known optical analogue: Light of short wave-length is more dispersed in certain optically turbid media than light of greater wave-length.

21. To judge from the behaviour of the gases here observed, the occurrences in the ether, which make up the nature of the cathode rays, must be occurrences of such extraordinary delicacy that dimensions of molecular magnitude enter into consideration. Even to light of the smallest known wave-length matter behaves as if continuously filling space; but in the presence of cathode rays the behaviour of elementary gases even is that of non-homogeneous media; here each single molecule appears to act as a separate impediment. Gas molecules make the ether turbid, and it is very remarkable that in this case no other properties of the molecules are of any moment except their mass alone. The total mass of molecules contained in unit volume determines the turbidity of the medium. When the gas molecules are replaced by coarse suspended particles, and the cathode rays by light, equal appearances are presented, but in that case the behaviour of the medium is hardly determined by a single and equally simple problem.

M. HERMITE'S ELECTROLYTIC SEWAGE PROCESS AT WORTHING.

The report of Dr. Kelly, the Worthing Medical Officer of Health, on the results of the experimental treatment of sewage by the Hermite process at that town contains some valuable information as to the chemical and bacteriological actions of the Hermite electrolysed sea-water. A number of cottages have been supplied, each with (1) town water, (2) ordinary sea-water, and (3) electrolysed sea-water, for flushing purposes; and tests have been made on chemical and sterilising results obtained by these, as well as on the corrosive action of the last-named fluid. Chemically, the electrolysed sea-water was found to contain only one-sixtieth of the equivalent of chlorine that exists in a saturated solution of ordinary bleaching powder; while, after storage for only two days, as much as 5 per cent. of the strength of the solution disappeared. The solution does not contain free chlorine, as has been alleged, nor does it give an acid reaction. As compared with a strong solution of bleaching powder, the Hermite fluid will not act so powerfully, neither in reducing the offensive odour or breaking up the solidity of sewage, nor in corroding vessels in which it may be contained. Dr. Kelly finds that a few days' exposure to mortar produces slight flaking, while the metals copper, brass, bare iron, and galvanised iron are appreciably corroded. No effect was observed to take place with contact between the fluid and cements. The bacteriological experiments by Dr. Klein, F.R.S., which Dr. Kelly embodies in his report, are, it would seem, a striking proof that the Hermite process, as carried out under M. Hermite's direction at Worthing, is incapable of sterilising sewage—*i.e.*, of ridding it of either sporing or non-sporing bacilli. Cultures in gelatine of (1) the ordinary sea water, (2) the Hermite fluid, and (3) the freshly-treated sewage gave the following results:—Bacilli in immense numbers were found in the ordinary sea water, but the Hermite fluid proved to be perfectly sterile, showing that the direct electrolysis causes sterilisation. The freshly-treated sewage, however, produced an enormous number of colonies of microbes, after only 48 hours' culture. In fact, it was estimated that the original treated sewage, before culture, must have contained from 800 to 1,000 living microbes of various kinds per c.c., many of these being of the non-sporing varieties which it has been claimed are destroyed by the process.

Although, at the present time, the Hermite process appears to be but an imperfect success, we hope it will ultimately be improved sufficiently to compete on an equal footing with the chemical processes now commonly used.

* *Wied. Ann.* 19, p. 816. 1833.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, April 6th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting at 28, Victoria-street. The following paper will be read:—"Notes on Alternate Current Transformers," by A. F. Berry.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read: "The River Humber," by W. H. Hamer, Stud. Inst. C.E.

ROYAL INSTITUTION.

9 p.m. Friday Evening Discourse. "Destructive Effects of Projectiles," by Prof. V. Horsley, F.R.S.

MONDAY, April 9th.

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting at the Palatine Hotel, Hunt's Bank, Manchester. Continuation of Discussion on: (1) "Notes on Designing a system of Underground Electric Light Mains," by John H. Rider, (2) "The various Systems of Underground Mains and Methods of Laying Same," by S. V. Clirehugh. After which the following Paper will be read:—"Electricity Meters," by R. P. Wilson.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture. "Photometry," by Capt. W. de W. Abney, F.R.S.

TUESDAY, April 10th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Electric Illumination," by Prof. J. A. Fleming, F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. The following Paper will be further discussed: "The Construction of Gas Works," by Charles Hunt, M.Inst.C.E.

WEDNESDAY, April 11th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. The following Paper will be read: "London Coal Gas and its Enrichment," by Prof. Vivian Lewes.

THURSDAY, April 12th.

TRAMWAYS INSTITUTE.

11 a.m. Council Meeting at the Albion Hotel, Manchester. To be followed by (1) Report of Committee on the Board of Trade Regulations for Electric Traction; (2) Discussion on Mr. Schwann's Bill to Enable Local Authorities to work Tramways; (3) Paper on: "Mechanical Tramway Electric Traction," by Victor Popp; (4) Paper on: "The Heating of Railway and Tramway Carriages," by Frank Mellersh; (5) Paper on: "Vereker and Yeats' Car Starter," by H. L. Furlonge.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting at 25, Great George-street. Discussion on: "The Best Resistance for the Receiving Instrument with a Leaky Telegraph Line," by Prof. W. E. Ayrton, F.R.S., and C. S. Whitehead, M.A. After which the following Papers will be read: (1) "Transparent Conducting Screens for Electric and other Apparatus." (2) "An Astatic Station Voltmeter," by Prof. W. E. Ayrton, F.R.S., and T. Mather. (3) "Cost of Electrical Energy," by R. E. Crompton.

FRIDAY, April 13th.

INSTITUTION OF CIVIL ENGINEERS.

2 p.m. Students' visit to Barnes Bridge, London and South-Western Railway, to inspect the sinking of a Caisson; and subsequently to the new Lock and Weir at St. Margaret's, Richmond.

PHYSICAL SOCIETY.

5 p.m. Discussion on: "Calculating Machines," by Prof. O. Henrici. After which the following Papers will be read: (1) "The Minimum Temperature of Visibility," by P. V. Gray. (2) "The Mechanism of Electrical Conduction," by C. V. Burton.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Ordinary Meeting at Westminster Palace Hotel. The following Paper will be read: "Lubricants: their Use, Testing, and Analysis," by William F. E. Seymour.

ROYAL INSTITUTION.

9 p.m. Evening Discourse on: "Some Properties of the Electric Discharge through Gases," by Prof. J. J. Thomson, F.R.S.

⁂ Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny

Editorial, Publishing, and Printing Offices :

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies :—

Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

The same book in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

LIGHT ELECTRIC RAILWAYS.

Alone almost amongst our daily contemporaries, *The Times* devotes an appreciable proportion of the space not occupied by political disquisitions and money matters, to such solid fare as India, the Colonies, and Agricultural Depression, and it is as a panacea for this national complaint that two long articles and a leader have recently been given over by *The Times* to the consideration of the subject of "Light Railways." Now Light Railways should possess peculiar interest for the electrical engineer, since it will be largely his own fault if he does not have the constructing of most of them. The connection between the building of light railways and the removal of agricultural depression is not, perhaps, immediately obvious, but may be established somewhat in this wise. At every turn the British farmer has to compete with the produce of more genial climes, brought to the home market from far afield cheaply, rapidly, and in large quantities. To restore equilibrium, if only the state of meteorological science permitted it, we might purge our own climate of its manifold defects or alloy that of our rivals. The imposition of that much-coveted small tax on foreign farm produce might effect something, but such a consummation is not just now particularly hopeful; there are too many people who still regard this modernised version of bringing in the New World to redress the balance of the Old as one of the greatest blessings of the century. Nor, again, would it be possible, humanly speaking, to impede the free flow of the fruits of the earth by depriving foreign producers of their transport facilities. British shipowners and others would have something to say to that. Remedies there still remain; rents still lower, more economical and scientific farming, better organisation would do much, but, according to *The Times,* light railways would do more. Since the British farmer cannot injure his enemies' means of communication, let him set to work to

Digitized by Google

improve his own. Just so far as the suggestion leads to self-help and increased enterprise it will tend to do good; and just so far as it results in grants, subsidies, and such-like artificial stimulants, it will work mischief.

Up to the present it must be confessed that light railways have not, from the dividend-earning point of view, altogether justified their existence. In France, where there are over 2,000 miles of *chemins de fer d'intérêt local*, it is needless to say they are State-aided, but neither the system of lump-sum subsidies nor that of annual payments to make up the interest to 5 per cent. has been found to work well; the average cost per mile has, moreover, been about £7,000, not far short of the mileage cost of a country line built to the liking of the Board of Trade. The French have sunk no less than £15,000,000 in these local lines, the working expenses of which leave only £80,000 for interest, so that nearly £700,000 have to come out of the taxpayers' pockets to keep the interest up to the 5 per cent. level. In spite of this heavy direct loss to the State, the building of light railways, we are told, is being pushed on at this moment more energetically than ever; "the pressure of politicians anxious to secure a benefit to their constituents at the public expense" largely accounting, it is stated, for the strange phenomenon of the eager pushing on of an apparently unprofitable business. Italy, on the other hand, appears to have made a somewhat better job of its steam tramways, the average cost of which is given at under £2,000 per mile, though nothing is said about profits. In Belgium a continentally complicated mode of subscription of the necessary capital finds favour; 25 per cent. of the money is found by the ever-obliging State, 25 per cent. by the provincial authorities, 40 per cent. by the communes directly affected, and some 10 per cent. by private persons. The average cost per mile is under £3,000, and the average interest in 1891 was 2¾ per cent. In Holland the light railway idea, as we can testify by personal experience, is carried out in excellent style; the lines are almost invariably laid along the public roads, they pay some 8 per cent., and, pleasant to record, they receive no State subsidy, though the local authorities occasionally subscribe 10 per cent. of capital.

Such is the record of light railway enterprise on the Continent. What need have we in this country for any such lines? what chance have they of paying? by whom and in what style should they be carried out? Judging merely by the mileage statistics of similar countries, the need in which we in England stand of light railways is neither greater nor less than is the case on the Continent. Whilst we have more railways to the square mile than Germany or France, we have nothing like so many as Belgium or Saxony, and it must be remembered that there is an enormous concentration of railways in the manufacturing regions of the North, which has no parallel in any Continental country, and which makes the mileage of our agricultural districts considerably lower than the average. Again, English highways, whilst superior to most Continental ones, are undoubtedly inferior to some, notably those of France. On the other hand, seeing the admittedly high capital cost of our railways, it can scarcely be possible that the cost of carriage, even if we take into consideration the questions of superior speed, care in handling, and frequency of service, is as low at home as abroad. The need, therefore, for light railways does not seem to be such as would justify us in following the bad example of our Continental competitors and to dip into the Imperial Treasury, or even, for matter of that, into the ratepayers' pockets. We are constantly told, and there can be but little doubt about it, judging by the steady stream of English gold that flows into apparently bottomless foreign pockets, that there is a glut of capital in the country, so we may be perfectly certain that if it can be shown that light railways are likely to return even 3 or 4 per cent. on the capital outlay there will be no lack of funds. What Parliament and the local authorities can do to encourage such undertakings is, on the one part, to considerably simplify and cheapen the at present costly and cumbersome mode of procedure in obtaining statutory powers, and on the other, to refrain from squeezing all manner of small but expensive concessions out of the unfortunate individuals who are anxious to lend their money. Another necessary antecedent to the construction of light railways is undoubtedly the infusion of a little more "adaptivity" into the cast-iron rules of the Railway Department of the Board of Trade. It is a proud boast that we English have but one standard of railway construction and railway working—the best; but one very obvious result of our being satisfied with nothing but the best is that we often have to do without the good. These light railways must not be treated as anything more serious than long-distance tramways, to which it would be pure pedantry to apply the rules and regulations intended for quite other conditions. The Troon-Annbank line, instanced by Mr. ACWORTH in an article in a recent number of the *Engineering Magazine*, is a shocking example of the standard we are likely to have to live up to in the matter of light railway construction unless we are permitted to aim somewhat short of the admirable ideal of the Board of Trade. The Troon Harbour-Annbank Collieries line is only three miles long; it is single track throughout, there is no station on it, and no passenger trains are run; nevertheless, it has all the paraphernalia of a London and North-Western main line, and has cost £33,000 or £11,000 per mile, which is not surprising, considering that there are amongst many other unconsidered trifles no less than fifteen over and under bridges. In the same way that Dutch experience emphasises the fact that light lines of railway can be made to pay their way without any system of outdoor relief from the State, it points to the necessity of running these lines along the country roads; embankments, cuttings, viaducts, stations, signals, soon pile up the capital cost, which it is admitted on all sides must be kept low. Here, then, local authorities have an opportunity of benefiting the community by simply granting, on easy terms, the right to use the highways for tramway purposes. And it is this necessity for cheap construction, and the laying of the track along the high roads, which points, in our opinion, to the extensive use of electricity on our light railways, if ever they are built. By the use of motor cars, not only do we secure immensely greater tractive effort per ton of motive apparatus than is the case with steam locomotives, but the whole system gains a flexibility and an immunity from complete breakdown that can be obtained in no other way. Along quiet country roads, and past farmyards and hayricks, steam locomotives, with their sparks, smuts, and clatter, are altogether inadmissible. In Ireland, it seems, they run on the few lines already constructed only two *trains* a day, at almost impossible fares and rates, and the result, of course, is failure. To ensure success there should be light motor cars, with a reserve of motive power in order to pick up a "trailer" or two if need be, running at comparatively short intervals, and wherever the line feeds a railway, if not in every case, the gauge should be the normal 4ft. 8½in. gauge, to permit of trucks, &c., being run straight on to the local line. It is extremely difficult to tell beforehand whether there really exists a need for any given new thing, but it seems to us that there is a

Digitized by Google

sufficiently good *primâ facie* case for light railways in our agricultural districts to make it advisable that all artificial impediments, such as the existing costly and cumbersome Parliamentary procedure and the blackmailing raids of our local authorities should be swept away; then, if there be really any money in the business, light railways will be built, largely, we hope, with local capital, not one single mile, we trust, under State or municipal patronage.

REVIEWS.

A Pocket-Book of Electrical Engineering Formulæ. By W. Geipel and M. Hamilton Kilgour. Published by *The Electrician* Printing and Publishing Company, Salisbury-court, Fleet-street, E.C.

"Although this pocket-book" (to quote the preface) "has been compiled to some extent on the lines of other pocket-books, yet an attempt has been made to supplement the rules and formulæ by brief descriptions of the various subjects treated." The book is published in two forms, one for the desk and one for the pocket. It may be said to consist of a set of very compressed treatises on the group of subjects, mathematical, engineering and electrical, which are usually included under the head of electrical engineering. It is divided into about forty-two sections. Of these, seventeen cover matters which are chiefly electrical, eleven the mathematical groups, and twelve are devoted to such subjects as engines, boilers, steam piping, &c. In a pocket-book designed on these lines, and which is not merely a collection of tables, the difficulty is to know what to put in and what to leave out; but the authors have succeeded in gathering together a considerable amount of information and arranging it in a fairly systematic way. The book begins with the usual definitions of terms, and we then have useful tables on the properties of materials, specific gravities, specific heats, electrochemical equivalents, &c. In the table of thermo-electric powers, we note the omission of the thermo-electric powers of antimony and bismuth. The tables of specific electrical resistances are given in "legal microhms," but it is not stated what this "legal microhm" is. If it is derived from the unit adopted by the Paris Congress, and which has never, in Great Britain at least, been "legalised," then the values should be altered so as to express them in terms of the unit of resistance recommended by the Board of Trade Electrical Standards Committee, and which will no doubt be generally adopted under the name of the international ohm. In the mathematical sections there are useful tables for aiding the student in trigonometrical transformations, also standard forms of differentials, integrals, and differential equations, tables of sines, cosines, &c., and also hyperbolic sines and cosines. A handy section on the use of the slide rule and logarithms is appended. The usual tables of squares, cubes, logarithms, &c., are not omitted. The mathematical section is, on the whole, very well written. The sections of the book which are purely on mechanical engineering, as above observed, are practically short treatises on engines, boilers, and steam and hydraulic work generally. The very compressed nature of these renders it impossible to find space to quote authorities or to enter into discussion of empirical formulæ, and there is, therefore, a risk of the inexperienced reader being led to place too much confidence in a formula or result. It will always be a matter of opinion how far in such highly technical subjects as these it is desirable in a pocket-book to go beyond tables of results. There is, however, an immense amount of highly concentrated information on steam engines, gas engines, oil engines, water motors, and on the subject of steam generation and use, which is presented in a very readable form. The electrical sections of the book cover the usual subjects of dynamos, transformers, batteries, arc and incandescence lamps, &c. There are also brief chapters on the above subjects, and are generally well written and arranged. The section on secondary batteries would bear amplification. The chapter on electrical testing, however, omits to mention several matters of practical importance. On page 572, sine should be cosine, or $E=E_0$ should be $E=0$, and so throughout the section.

In an electrical pocket-book it would, we think, have been better to sacrifice some of the space given to subjects of mechanical engineering and devoted it to more ample explanations in the section on electrical testing. This section would have been improved by the insertion of figures of the actual electrical instruments in addition to mere skeleton diagrams of connections. Considering the extremely simple and accurate methods of dynamo testing which are based on the use of the potentiometer, we think that a fuller account should have been given of that method of testing and of the precautions to be used. The favourite text-book methods for testing the internal resistance of a cell are in general perfectly useless, but the potentiometer enables an accurate and speedy test to be made of the behaviour of any primary and secondary cell when in action. This section will, we think, bear enlarging in another edition, because so much of what is given under the head of electrical testing in other similar books is limited to purely academic methods or to telegraphic work. The student requires to be told what are the precautions to be taken to obtain correct results, and to be warned on the sources of error. In spite, however, of some omissions, the electrical sections of the pocket-book are carefully written, and bring the information fairly up to date, and the book will prove useful to most of those engaged in any form of electrical work. J. A. F.

MAGNETIC QUALITIES OF IRON.*

BY J. A. EWING, F.R.S., AND MISS HELEN G. KLAASSEN.

Recent applications of electricity, and especially the extended use of transformers, have added particular interest to the study of cyclic magnetising processes in iron. It has become a matter of consequence to investigate, in various specimens of metal, not only the amount of the energy dissipated by hysteresis in a magnetic cycle, but the relative amounts under various degrees of magnetisation and various intensities of magnetising force. Other questions arise with regard to the dependence of this loss on the frequency of the cyclic process and on the manner in which it is performed. The experiments to be described in this Paper deal mainly with the effects of cyclic variations of magnetising force. They are intended to contribute some additions to existing data, to answer one or two specific questions, and to exemplify certain more or less novel methods of experimental inquiry. A section at the end of the Paper relates to the molecular theory of magnetisation, and its adequacy to explain some characteristic manifestations of magnetic hysteresis.

Experiments on Rings, by the Ballistic Method.

In a Paper published eight years ago by one of us,† experiments were described in which a piece of soft iron was carried through a numerous series of cycles of magnetisation, of graded amplitude, with the object of determining the form taken by the curve of magnetisation and magnetising force during the process of reversal between any assigned limits, and of comparing the work spent in the process with the amplitude of the magnetisation. A similar experiment was described for steel. Since then the importance of such information has been recognised by electrical engineers, and some experiments with a similar object have been made by Messrs. Evershed and Vignoles,‡ and by Mr. C. P. Steinmetz.§ Notwithstanding, however, the increased interest which now attaches to the matter in consequence of its practical bearing, the available data are still meagre. By way of adding to them, we have made a detailed examination of some ten samples of wire and sheet iron, arranged in the form of rings to be operated on by the ballistic method.

* Abstract of Paper read before the Royal Society.

In the former tests, referred to above, the method used was to make direct observations with a magnetometer, the samples being then long, straight pieces of wire. When the metal to be examined is in the form of wire, which may be taken long enough to secure practical endlessness, or of rods or bars big enough to be turned down into ellipsoids, the direct magnetometric method is entirely suitable. Several of our samples, however, were to be cut out of plate or sheet metal, such as is now largely used in the manufacture of transformers; and for this reason, as well as because direct measurements were to be made of the heating effect of magnetic reversals (which made ring samples most eligible), the ballistic method was selected, and a somewhat novel form was given to it, to allow points on the cyclic curve to be accurately and conveniently determined by its means.

In the Paper already cited, some ballistic observations of magnetic cycles were described, in which the successive points on the cycle were determined by summing the ballistic effect of successive steps, in each of which the magnetic force underwent a small sudden change. This method is, at the best, laborious, and requires great care to avoid the carrying forward and accumulation of errors. The accuracy of each point depends on that of the points before it, though at the end of the process a check may be applied by comparing the ballistic effect of a sudden reversal with the sum of the effects of successive steps. There is an obvious advantage in making the determination of each point independent of the previous readings of the ballistic galvanometer, and, recognising this, Messrs. Evershed and Vignoles introduced, in their experiments, the plan of reading each point by a single step from the terminal condition of magnetisation represented by one or other extremity of the cycle. They wound their ring with two coils, through one of which a constant current was maintained; through the other coil a current, opposite in magnetising quality, could be passed, and its strength could be varied up to a maximum which made its ampere-turns just twice the ampere-turns of the other coil. Then, when current flowed in the first coil only, the magnetisation had its extreme positive value. By suddenly applying a current in the second coil, it was altered to any value between the positive and negative extremes. The use of two currents is an undesirable complication, especially as the symmetry of the resulting curves depends on the exactness with which the magnetising effect of the one is adjusted to be at its maximum, just twice that of the other. We have devised, and used throughout all these experiments, a method which, while requiring only one current and one magnetising coil, retains the advantage that each point in the cycle is reached by a single step from the end of the cycle.

The diagram (Fig. 1) shows the arrangement used.

The magnetising current passes from the battery through the adjustable resistance R_1 and the galvanometer G_1 to a key, K, and thence, through the resistance R_2, to a two-way plug, P, which allows it to be sent either into the magnetising coil of the ring A, which is the sample under test, or into the primary of a special induction coil, C, which is used for standardising the ballistic galvanometer. A and C each have a secondary coil; the two secondaries are kept in series with one another, and their circuit is completed through the ballistic galvanometer G_2. A Kelvin balance, B, which is short-circuited when it is not required, serves to determine the constant of the current galvanometer G_1. The key K is a rocker, working in mercury cups, which, when rocked to the left, connects *a* with *e* and *b* with *f*, and, when rocked to the right, connects *a* with *c* and *b* with *d*. In the latter position of the key, the full strength of the magnetising current is in action, and hence, if the plug P is set so as to send the current into A, the sample is magnetised to a degree which represents one extremity of a magnetic cycle. Between the cups *e* and *d* of the rocking key are a short-circuit plug and also an adjustable resistance, R_3. When this short-circuit plug is inserted, the key K is simply a reversing key, and then, when rocked to the left, it reverses the magnetisation of the ring, carrying it at once to the opposite end of the cycle. But when, instead of a short circuit between *e* and *d*, there is a resistance, the rocking of the key to the left applies to the sample a magnetising current opposite in sign to the primitive current, but less than it in amount, and consequently carries its magnetism not to the end of the cycle, but to a point which falls short of the end by an amount depending on the magnetism of the resistance R_3. The peculiarity of the method is that, by a single movement of the key, the magnetising current is at once reduced in amount and reversed in sign.* By giving R_3 a series of values, each movement of the key to the left determines a new point on the curve, while each movement to the right brings back the magnetisation to its extreme value. In this way as many points are found as may be required to define that part of the curve which lies between the zero of magnetising force and its extreme negative value. To find points lying between the positive extreme and the zero of magnetising force, a different process is adopted. The key is kept to the left, and a sudden reduction of the current (without change of sign) is effected by withdrawing a plug from the resistance box R_2. This gives a point in the first quadrant of the descending curve, and a series of such points are found by selecting successive values of R_2, the magnetisation of the sample being, however, restored to its initial full value before each such step.

To make the matter plainer, we may describe the operation of taking a cycle in detail. First, the strength of the magnetising current was adjusted by selecting a proper number of cells (a storage battery was used throughout) and by means of the resistance R_1, so that the limits of magnetisation should

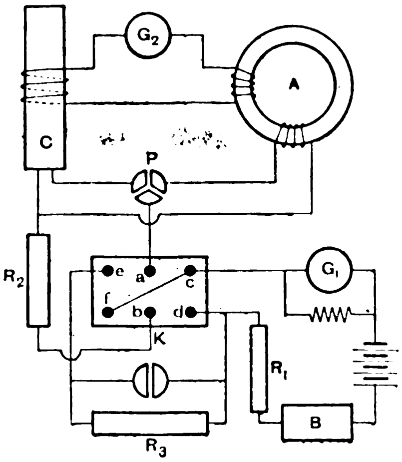

Fig. 1.

have the desired value. At this stage there was no resistance in R_2, and the short-circuit plug between *e* and *d* was in its place. The key K was now rocked back and forth many times to bring the magnetic changes into a thoroughly cyclic state—a precaution especially necessary when only a weak degree of magnetisation was in question. The ballistic effect of this reversal was observed, several times over. Then, with the key K leaning to the right, a small sudden reduction of current was made by removing a plug from R_2, and the ballistic effect of this was observed. The plug in R_2 was replaced, the key, K, rocked back and forth to put the metal through a cycle, and then a second resistance, larger than the first, was suddenly opened in R_2. Operating in this way, a series of points were found for values of the magnetising force H, lying between the positive maximum and zero. To continue the curve beyond the axis into the region of negative H, the resistance R_3 was adjusted to have, first, a rather high value. The key was then rocked from right to left, the ballistic effect being read; then this resistance was short-circuited; the specimen was taken through its full cycle by rocking the key; R_3 was set to be less than before, and its short-circuit plug was removed, the key was again rocked to the left, and so on. The curve determined by these successive operations

* Since this description was written, a Paper has been communicated to the Royal Society by Dr. John Hopkinson and Messrs. Lydall and Wilson, in which ballistic experiments are described where the method was essentially the same as that used by us. A single movement of a key reversed the magnetising current and introduced resistance (*Roy Soc. Proc.*, Vol. LIII., p. 352.)

Digitized by Google

was the curve A B C D (Fig. 2), in which (ordinates being magnetisation and abscissæ magnetising force) A is the extreme state, always reverted to between each operation and the next; A B is the position determined by plugging out resistances in R_2, and B C D by rocking the key K with successive (lessening) values of R_3. This curve completely defines the magnetic cycle, inasmuch as the return limb is symmetrical with the one sketched. As a matter of convenience in exhibiting the results, the portion C D may be sketched as extending from a point C′ back to the starting point A, as in Fig. 3, O C′ being taken equal to O C, and in this way the relations of the rising and falling curve to one another are more clearly shown. There is, of course, no need to draw the other half of the cycle. The ordinate of A is taken as equal to half the magnetic change which occurs on reversal of the full strength of the magnetising current.

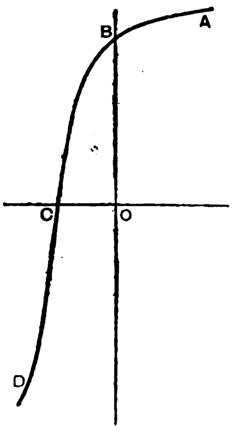

Fig. 2.

G_1, used in measuring the magnetising current, was a mirror galvanometer, strongly shunted and provided with a strong controlling field. Its constant in the shunted state was determined daily means of the Kelvin centi-ampere balance. The ballistic galvanometer was provided with a usual arrangement for applying electromagnetic impulses to stop the swing of the needle. Its readings were reduced to absolute measure by means of the coil C, an air induction coil, whose dimensions were accurately measured, and the coefficient of mutual induction of its coils calculated from them. Its induction was sufficient to give a ballistic deflection of the same order of magnitude as that given by the sample under test. The resistance of the

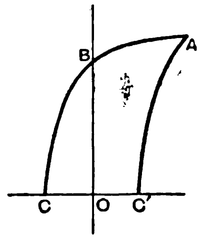

Fig. 3.

ballistic circuit was not altered throughout an experiment, and the two secondaries were permanently connected in series. The use of the coil C made the magnetic induction, as well as the magnetising force, depend for its interpretation in absolute measure on the standard furnished by the Kelvin balance. The resistance R_1 was a frame of platinoid wire, wound for these experiments; R_3 was, in the first instance, a liquid slide consisting of amalgamated zinc plates, immersed in a jar containing solution of zinc sulphate, but in the later experiments we found that a Varley carbon resistance, consisting of a pile of discs adjustable by compression, formed a very convenient substitute, especially when supplemented by short shunts of platinoid for the lower values of R_3.

All the samples tested in this set of experiments were arranged in the form of rings, with a mean diameter, generally, of about 10cm., and an area of cross-section of from one to two square centimetres. The magnetising coil was wound uniformly round the whole ring, in a single layer or in two layers. A few turns of wire, wound outside of that, formed the secondary or induction coil, the number of these turns being chosen so that reversal of the strongest magnetisation produced as large a throw as could conveniently be read on the ballistic galvanometer. In several instances pairs of rings were prepared, exactly alike in all respects, for the purpose of making certain special tests which will be described later.

With each sample a series of cycles were determined, generally ten or twelve, beginning with one in which the limiting magnetisation was strong, and working down to cycles on which the range was so small that the effects of hysteresis nearly disappeared. In the case of one or two samples a supplementary examination of the smaller cycles was made on a finer scale, by means of another secondary coil with a considerably larger number of turns, while the scale of the current galvanometer was at the same time altered by using a weaker shunt. We shall now give the results of the tests in detail.

Ring I.—In this ring the core was of fine iron wire, insulated by a winding of cotton. The diameter of the wire was 0·02475cm. It was supplied (by Messrs. Glover) as a specimen of soft iron, but the tests showed that it had either not been softened, or had been insufficiently softened after its last passage through the draw-plate, the curve of magnetisation presenting, to some extent, the characteristics of those for unannealed metal. Eleven cycles were examined; the results are shown by the curves of Fig. 4. The figures give the magnetic force **H** and the magnetic induction **B**, both in C.G.S units.

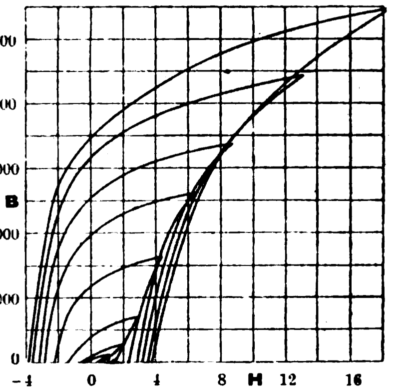

Fig. 4.—Ring 1. Fine Iron Wire.

In addition to these, three higher cycles were taken, with limiting values of **H** and **B**, as under :—

Limit of H.	Limit of B.
55·8	16,640
34·4	14.810
25·3	12,940

These, however, are omitted from the figure, as they would have required it to be drawn to an inconveniently small scale.

Inspection of Fig. 4 brings out one curious feature in the relation of the successive cycles to one another, which, however (as other figures will presently show), is of quite general occurrence. The extremity of each cycle lies outside of the rising curve of the immediately higher cycle, provided there is no very great difference in their ranges of magnetisation. It is only when we come down to the lowest cycles, where the steps by which **B** is reduced from cycle to cycle are relatively great, that this does not happen. It should be remembered that each of these cycles is taken only after a large number of reversals of that particular magnetising force which determines its range. During these reversals the range became somewhat reduced, especially when the magnetism does not approach saturation.

From these curves, by measuring the enclosed areas, values have been found of the energy dissipated in performing the magnetic cycle, namely, $\int H\, dI$ or, $\frac{1}{4\pi}\int H\, dB$.

Digitized by Google

Ring I.—Fine iron wire. Energy dissipated in cyclic process of double reversal of magnetism. The results are given graphically in Figs. 7 and 8, along with corresponding ones for the next ring.

Ring II. was of steel wire, of nearly the same fineness as the iron wire of Ring I. The diameter was 0·0257 cm., and, like the last, it was insulated throughout with cotton. Eleven cycles were taken in the first instance.

These results are also shown in Fig. 5 (Plate 34), where, however, Cycle 2 and the extremity of Cycle 1 are omitted to avoid overloading the diagram. Cycles 10 and 11 are also omitted. In drawing the curves the points corresponding to the readings actually taken are marked by dots enclosed within circles. They give satisfactory evidence that the method of

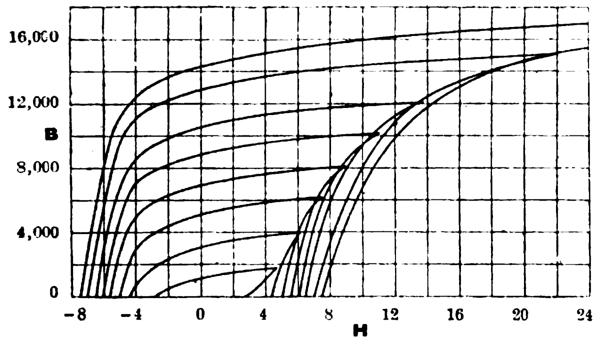

Fig. 5.—Ring 2. Fine Steel Wire.

observation we have used will yield a smooth curve. The curves here have the square-shouldered form, which is often found in steel as well as almost always in *annealed* soft iron. (The absence of this characteristic in Ring I., as well as its comparatively low permeability, was an indication of its being in a somewhat hard state.)

To test more particularly the action of weak magnetic forces Ring II. was further taken through a series of low cycles, the sensibility of the apparatus in regard both to ballistic and current measurements having been first increased in the manner already indicated. That is to say, an induction coil of a larger number of turns was now used, and the current galvanometer was less strongly shunted. Five small cycles were observed.

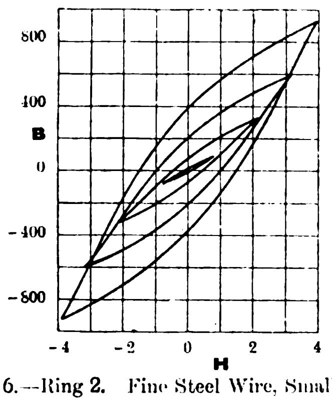

Fig. 6.—Ring 2. Fine Steel Wire, Small Cycles.

These, with the exception of No. 15, are drawn out in Fig. 6 (Plate 35). Measuring areas as before we find the energy dissipated in the cycles. Fig. 7 gives the value of $\int H\,dI$ for this ring and also for Ring I., in relation to H, and Fig. 8 (Plate 36) gives them in relation to B. Fig. 8*a* further shows to a larger scale the relation of $\int H\,dI$ to B in the low-cycle tests of Ring II. It is interesting, as an example of the growth of $\int H\,dI$ in the region of low magnetic force, when the effects of hysteresis are only beginning to be felt. The figures show in a striking way how small the loss of energy through hysteresis becomes when the limits of magnetisation or of magnetic force are restricted within certain values.

A characteristic of the curves of Fig. 5 is the remarkably uniform rate at which B changes with respect to H during a great part of the process of magnetic reversal. After the shoulder of the descending curve has been turned, by applying a sufficiently strong demagnetising force, the quantity dB/dH takes a large and nearly constant value, which it retains until a tolerably strong reversed magnetisation has been produced. The steep and nearly straight portion of the curve which corresponds to this part of the process has, moreover, nearly the same gradient in all except the smallest cycles. The same characteristic will be found in examples of annealed iron, to be given later, and the gradient in them is, of course, even steeper than it is here. In the present sample of steel wire (Ring II.), the maximum value of dB/dH is about 4,950; nearly half the whole magnetic change in the highest cycle

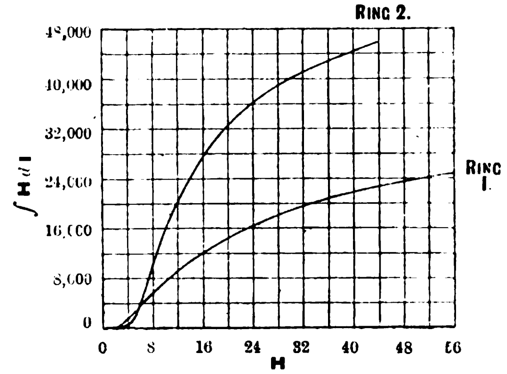

Fig. 7.—$\int H\,dI$ and H for Rings 1 and 2.

occurs at approximately this rate. In some of our soft iron samples dB/dH reaches a value nearly three times as great as this.

The amount of demagnetising force just sufficient to bring the magnetism to zero has been called by Hopkinson* the *coercive force*. It will be seen from these tests that the coercive force rises progressively as the magnetisation is increased. We have measured its values for the cycles of Rings I. and II., and these may conveniently be expressed in relation to the limits of H and of the intensity of magnetisation I.

In Fig. 9 the coercive force is plotted in relation to I. From this figure it is possible, by extrapolation of the curve, to arrive at a probable estimate of a definite physical constant of the

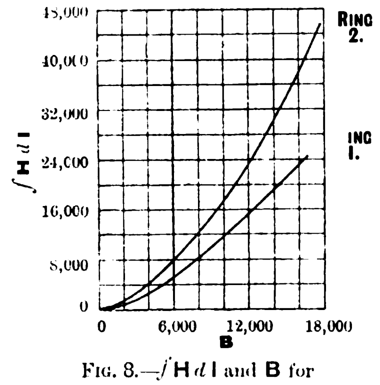

Fig. 8.—$\int H\,dI$ and B for Rings 1 and 2.

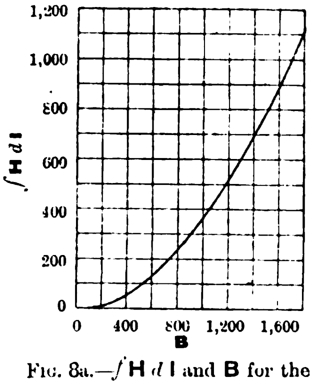

Fig. 8a.—$\int H\,dI$ and B for the Low Cycle Tests of Ring 2.

material which forms a good criterion of magnetic hardness, namely, the coercive force which would correspond to the state of magnetic saturation. This, in other words, is the demagnetising force which would be just sufficient to remove magnetism from a piece which had been magnetised to literal saturation. We know that the saturation value of I in wrought iron and steel is about 1,700.† A conjectural extension of the curves along the straight lines which they follow in the region of strong magnetisation shows that the coercive force of saturation is probably about 5·5 in the (rather hard) iron of Ring I., and 8·5 in the steel of Ring II.

* J. Hopkinson, "Magnetisation of Iron," *Phil. Trans.*, 1885, p. 460.

† *Phil. Trans.*, 1889, A, p. 221.

The next three rings had cores of sheet iron. Ring III. was made up of comparatively thick annular discs which were turned out of discs that had been supplied for the core of a dynamo armature. The mean thickness of the discs was 0·195cm.; the internal diameter of the annulus was 13·55cms. and its external diameter 1,545cms. Rings of paper were interposed to prevent the discs from touching one another. The tests showed that this iron compared well with most other specimens in the matter of magnetic softness.

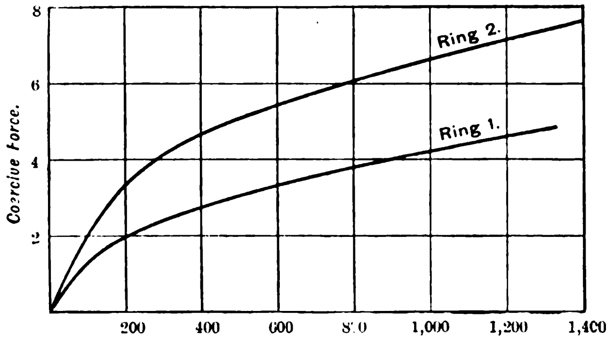

FIG. 9.—Coercive Force and I. Rings 1 and 2.

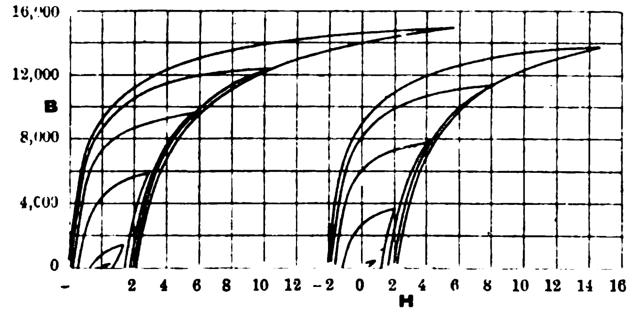

FIGS. 10 and 10a.—Ring 3. Thick Sheet Iron.

The cycles, with the exception of No. 1, are shown in Figs. 10 and 10a (Plate 37), where, to avoid confusion, the odd and even cycles are drawn separately. The values of $\int H\,dI$, in relation to B, will be found plotted in Fig. 21, along with corresponding results for other samples of sheet and wire iron.

(*To be continued.*)

POLYPHASE TRANSMISSION.*

BY CHARLES F. SCOTT.

Alternating Current Problems.

When the alternating current was introduced for lighting it presented many new problems to the electrical engineer. Numerous difficulties and dangers were predicted by the theorist, but in ordinary service most of these have fortunately lain dormant. These difficulties are apt to appear, however, when alternating current work is attempted on a large scale. The introduction of large units, heavier currents, higher potentials or power service, are apt to increase the effects of self-induction and capacity so that they demand careful consideration. The impetus which electrical engineering is receiving from the introduction of the polyphase system, which brings with it large units and long distances, naturally directs attention to the general problem of alternating current transmission and distribution. A complete and exhaustive solution of this problem is by no means a simple one, and the attempted solutions generally lead to formulæ and diagrams which are possibly even more perplexing than the phenomena.

The author then gives a number of explanatory diagrams, illustrating the effects of self induction. The important facts to be noted being—(1) that the sum of the alternating E.M.F.'s on the elements of an inductive series circuit is greater than that required on the terminals; (2) that the alternating E.M.F. for supplying glow lamps in series with a coil is greater than the continuous E.M.F.; and (3) that the difference between the two becomes greater as the number of lamps is increased. It is also to be noted (4) that if the same alternating current be supplied through a coil, first to a lamp alone and then to a combination including lamps and a coil, a higher E.M.F. is required when the combination is used. These relations, says the author, which seem rather perplexing, may be illustrated in a very simple way by diagrams. In

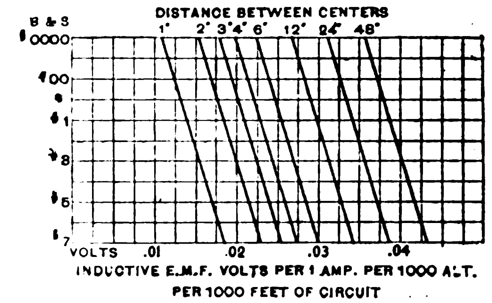

FIG. 1.

the case of a coil alone, in which 50 volts are required for producing one ampere alternating current, and 10 volts for one ampere continuous current, the two E.M.F.'s may be represented by the hypothenuse and one side of a right-angle triangle. The remaining side represents the counter E.M.F. in the coil.

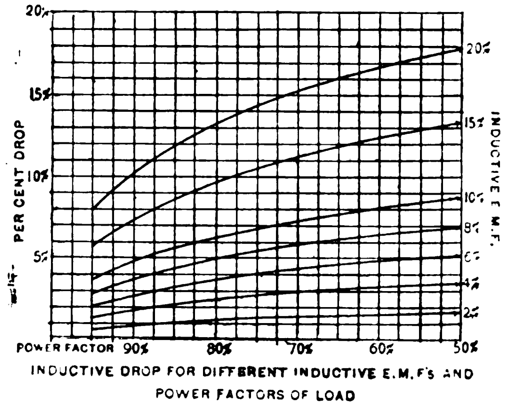

FIG. 2.

Calculation of Drop in Alternating Circuits.

The regulation of a circuit is in general determined by two elements; the counter E.M.F. of the circuit and the self-induction of the load. The counter E.M.F. of a line depends upon the size of wire and the distance between wires, and increases directly as

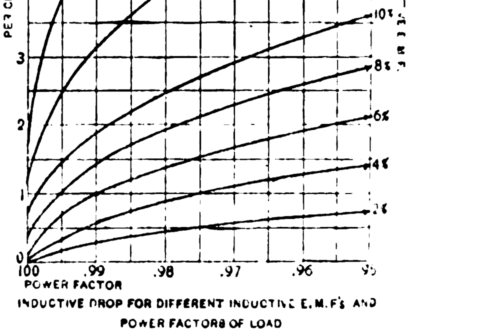

FIG. 3.

the length of the circuit, the current, and the alternations. The counter E.M.F. of a line has been calculated for a number of cases which are likely to occur in practice and the results are given in Fig. 1. The drop, or difference of potential between generator terminals and the load terminals due to the counter E.M.F. of the line

* Abstract of a Paper read before the National Electric Light Association, at Washington

Digitized by Google

depends upon the self-induction of the load. The latter is best expressed by a power factor or a factor by which the product of the amperes and volts giving the apparent energy must be multiplied to give the true power in watts. The drop due to self-induction on the line (which, plus the ohmic drop, will give approximately the total drop) corresponding to various power factors of the load is given in Figs. 2 and 3.

These relations may be elegantly determined by a simple diagram on section paper ruled in tenths. Draw an arc through a quadrant with a radius of 100. At a distance from the centre on the horizontal, equal to the power factor of the load, erect a perpendicular and extend it to the arc. This line represents the counter E.M.F. of its loads and its value read directly on the scale gives the counter E.M.F. in per cent. of the E.M.F. upon the load. From the intersection of the arc draw a horizontal line outside the circle equal on the scale divisions to the per cent. in terms of the E.M.F. on the load which would be required for sending the normal amperes continuous current through the line resistance. From the end of this horizontal line draw an upward vertical equal to the counter E.M.F. of the line expressed in per cent. of the E.M.F. on the load. A line from the centre to the upper end of this vertical represents in direction and magnitude the E.M.F. must be impressed on the circuit. If from the same centre an arc be drawn though this point to the base, the scale divisions on the base between the two arcs measures the total drop caused by the lines in terms of the E.M.F. on the load (Fig. 4).

Self-induction in Transformers, &c.

Self-induction exists in line, generators, transformers, secondary wiring, and sometimes in the load. In each case the effect of the self-induction upon regulation depends largely upon the self-induction of the total load supplied. Thus, the regulation of a generator depends upon the total self-induction of the line, transformers and load. Again, the regulation of a line supplying converters depends both upon the self-induction of the converters as well as that of the useful load. An ordinary transformer has a primary self-induction, a secondary self-induction and a mutual induction, which becomes a ready source of a very complicated and perplexing analysis when the complete action is described in theoretical terms. Practically, however, the action of the self-induction in the transformer may be expressed in a very simple way, and it is readily seen that this self-induction has a very important bearing upon the regulation of the transformer. The load may be non-inductive, or it may be more or less inductive. Arc lamps or fan motors will produce a very much greater drop than incandescent lamps. The power factor of an alternating current arc lamp varies considerably, but in a number of cases has been found between 85 and 90 per cent.

A secondary line, if it carry a large current, may have a counte E.M.F. of several volts. This may not be enough to increase appreciably the drop in the line between the transformer terminals and incandescent lamps. The transformer, however, delivers current to the secondary circuit and to the lamps, so that the regulation of the transformer may be effected by the self-induction of the secondary circuit. Cases have occurred in which transformers of a very old type, possessing high self-induction, were supplying very large secondary currents, and the resulting drop in the transformers was increased several per cent. For example, a circuit of No. 0000 B. and S. wire supplying 100 amperes to 50 volt lamps at a distance of 100ft. has an ohmic drop of 2 per cent. The constant for counter E.M.F. of this circuit, if the wires be 6 in. apart, is 0·022. The volts at 16,000 alternations are $0{\cdot}22 \times 100 \times 0{\cdot}1 \times 16 = 3{\cdot}52$, or 7 per cent. of 50 volts. The inductive drop in the line corresponding to 7 per cent. is 0·25 per cent. The power factor of the aggregate service of the transformer is the second side of a right angle triangle of which 7 is one side and 100 is the hypothenuse. This is 99·7 which is the power factor of the total load on the transformer. If the self-induction of the converter be 10 per cent., the inductive drop is 1·2 per cent. ; if 20 per cent. the inductive drop is 3·4 per cent., and if 30 per cent. the inductive drop is 7 per cent. The aggregate drop in the converter and secondary circuit in the latter case would be, say, 2 per cent. for ohmic drop in transformer, 2 per cent. ohmic drop in line, 7 per cent. inductive drop in transformer and 0·25 per cent. inductive drop in line, or a total of 11·25 per cent. The necessary ohmic drop is 4 per cent., and the inductive drop resulting from self-induction in transformer and line is therefore 7·25 per cent. If the number of alternations be reduced to 7,200 the inductive drop would be reduced from 7·25 per cent. to $1\frac{1}{2}$ per cent.

Ordinary Tests upon Transformers.

The practical bearing of the self-induction of a transformer upon its regulation and the exact relation between the two does not seem to be clearly recognised, and even Dr. Hopkinson and Dr. Fleming, who have made very exhaustive tests upon transformers, comparing different methods of testing and different types of transformers, have not brought out this point. Attention is given to the exact form of the current wave, and measurements upon the iron losses are attempted within very close limits of error. Their measurements upon the regulation of the same transformer, however, vary from 2 per cent. to 2·4 per cent. or one measurement is one-fifth greater than the other. The presence of a light induction in the secondary load would have caused a very considerable increase, and it is probable that the difference in the measurements made were due to difference in the self-induction in the instruments used or in the load at the time the

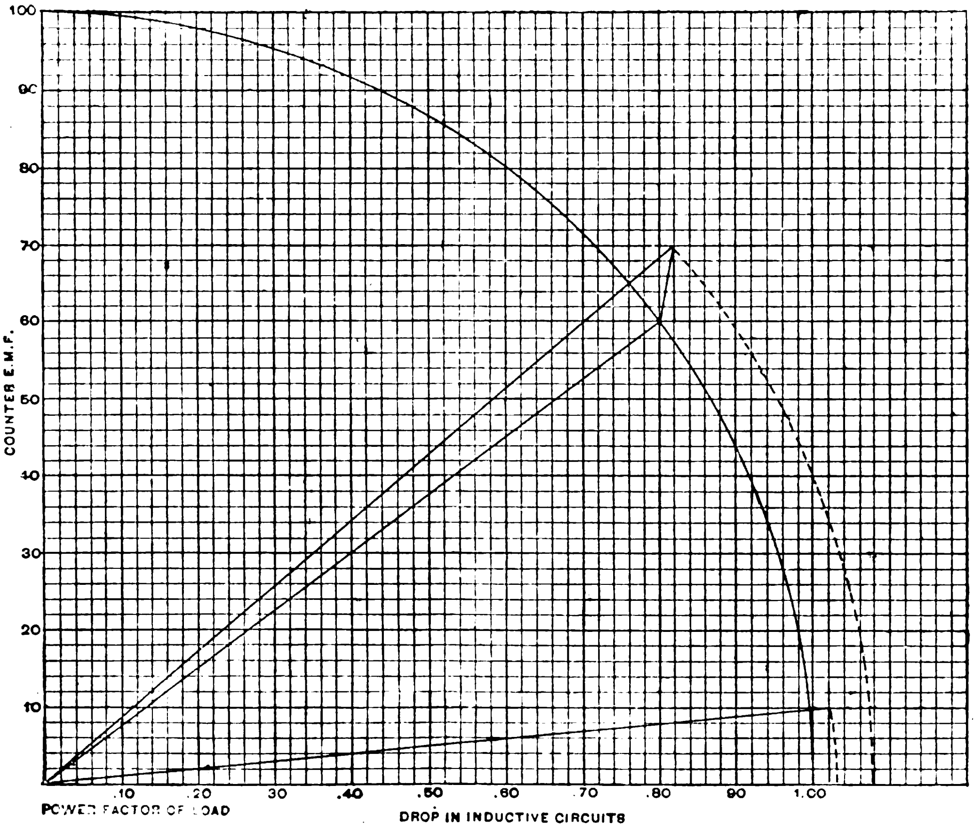

Fig. 4.

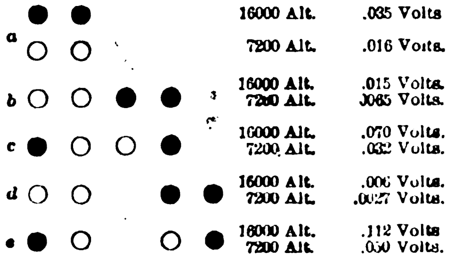
Digitized by Google

tests were made. No note is made of the effect of the self-induction of the load upon regulation, although regulation is one of the most vital points in the practical use of transformers. Even the temperature at which the drop was measured is not stated, although the resistance of a transformer when continuously working may be 20 per cent. greater than when cold. The elements of practical importance in a transformer are (1) the iron loss, in respect to the efficiency; (2) in the regulation, in respect to the satisfaction of service; and (3) the temperature to which the insulation is subjected, as affecting the life of the transformer. In the ordinary tests by theoretical men, the iron loss is measured to a very high degree of refinement, although the iron loss in transformers is the one thing which cannot be controlled, and is certain to vary 10 to 15 per cent. in commercial manufacture of transformers of the same size. The wave form of E.M.F. on different dynamos or the difference in form under different conditions of load on a circuit may make the loss under different commercial conditions vary several per cent. This renders more refined measurements of no practical use unless the conditions are stated. The temperature of the iron also affects the loss. The full load efficiency is usually given as if it had a great deal of importance, whereas the losses in copper during 24 hours ordinarily amount to but a trifling per cent. of the total losses. The regulation, and the temperature to which the insulation is subjected and which it is able to stand are generally not mentioned in reports of tests. The usual investigations and the papers published on the alternating current transformer may perhaps accurately express many facts in complicated formulæ, but the practical bearing of these points in every-day working seems to be totally ignored.

Mutual Induction.

If two circuits be run on the same pole line they act as a transformer in which one circuit carrying current may act as a primary and induce E.M.F. in the other as a secondary. If the two circuits be connected to different dynamos which are running at slightly different speeds, then the E.M.F. induced by one circuit



Volts in One Circuit Induced per 1,000 feet per Ampere in the Second Circuit.

FIG. 5.

upon the other will sometimes increase and at other times decrease the E.M.F. of the circuit, depending upon whether the two currents at a given moment are flowing in the same or in opposite directions. This fluctuation may cause variations in the intensity of the lights supplied. It is readily detected in the service of some central stations, and is, of course, more marked at time of full load, as the induction of one circuit upon another depends upon the strength of current carried. The fluctuation due to this action may be readily distinguished from that due to the slipping of belts or irregularity in engine speed. The fluctuation due to mutual induction of lines occurs only at the end of the line and is not observed in the station, while the other causes affect the station lights also. The number of volts E.M.F. set up in one circuit by a parallel circuit depends upon the current, the distance which the lines are parallel, and upon the relative positions of the four conductors. The distance between wires may be 6in. or 6ft. without affecting the mutual induction, provided the relative positions be unchanged. Several dispositions of circuits are shown in the diagrams (Fig. 5), and the number of volts per thousand feet at 7,200 and at 16,000 alternations, which are induced in either circuit by one ampere in the other, are given in connection with each diagram. The number of volts required for producing objectionable flickering in the light depends upon the voltage of the lamps in service, the efficiency at which they are run and the general surroundings in which they are placed, notably the relation of lamps to reflectors, white walls, &c., and the general disposition of the customer. An E.M.F. of ½ per cent. induced in one circuit by another can in some cases be detected, and usually more than 1 or 2 per cent. will cause objectionable flickering.

The mutual induction is reduced by bringing the wires in each circuit close together and separating the circuits.

Polyphase Circuits.

The subjects which have so far been considered apply to single-phase as well as to polyphase circuits. The effects of self-induction will be brought to the attention of the electrical engineer much more prominently in connection with polyphase work, however, because larger alternating-current enterprises will be carried out with the polyphase system, and power work involving variable power factors will be a large element in this system. There are, in addition, several problems which relate distinctively to polyphase working. One of these is the most suitable number of phases to be used. The two-phase system and the three-phase system are both in operation, and, while it is admitted by the adherents of each system that there is no fundamental difference between them, yet each has specific characteristics giving particular advantages.

Advantages of Three Phases.

In transmission it has been recently emphasised by a good many people that the single-phase system and the two-phase system require the same weight of copper, and that the three-phase three-wire system requires 25 per cent. less for transmitting power under similar conditions with the same maximum E.M.F. This places an advantage on the side of the three-phase system which in many cases is of very considerable importance. The aggregate advantage, however, is greater than 25 per cent. A two-phase system laid out for the greatest economy requires that the interest on the cost of conductors shall equal the cost of the power lost. If the three-phase system be substituted the loss may remain the same, and the copper will cost 25 per cent. less. This does not give the best relation between cost of copper and loss of power, so that a more economic adjustment is evidently possible.

It has also been shown that the self-induction of a three-phase three-wire circuit for transmitting under similar conditions of E.M.F. is only 57 per cent. of that which is incident to the two-phase four-wire circuit. When the power factor is high the effect of self-induction of line upon regulation varies approximately as the square of the counter E.M.F. The drop due to the self-induction of a three-phase circuit is, therefore, only about one-third of a single-phase or two-phase circuit. This is a second advantage for the three-phase system which is of great value. A further advantage of three instead of four wires is the reduced cost of insulators and pole construction, the reduced losses due to leakage, &c.

Advantages of Two Phases.

An important difference between the two systems is the effect of loading one branch of the system more heavily than the others, as is common in incandescent lighting. One of the statements which remain uncontroverted in Prof. Forbes' recent comprehensive and remarkable paper upon the electrical transmission of power at Niagara Falls is in reference to the difference of regulation in dynamos for two-phase and for three-phase alternating currents. He gives the result of tests showing that the circuits of a three-phase generator differ greatly in pressure if they are not equally loaded, and states that, having considered these points, the directors of the company determined to reject the three-phase system. These results agree fairly well with tests which I have made. The relative regulation of the two types of machine depends very largely of course upon the character of the construction. Although it is not just to condemn one system because a certain construction is bad, yet the theoretical and practical tendencies toward the evil are largely removed by discarding the three-phase type.

If independent regulation of circuits is necessary, one circuit can be given the proper pressure directly from the dynamo and the other circuits may be raised or lowered as may be required. This involves apparatus for regulating two circuits if the station be operated by the three-phase system, and only one circuit if the two-phase system is in use.

In a system where incandescent lighting is to be a prominent feature, or where load of any kind may be required upon one circuit and not on the other, the two-phase system has therefore a decided advantage in station regulation over the three-phase system. Another advantage of a two-phase circuit is that the load is separated into two divisions instead of three divisions, which is in general much simpler. A further advantage of the two-phase is in the reduction of potential for motors. Two transformers are sufficient in the two-phase system, whereas three transformers are commonly used in the three-phase system. The two transformers which would be required for small motors will cost considerably less than the three transformers which would be required on the three-phase system, and the loss in transformation will be much less, as there is not much difference in the cost of small transformers of slightly different sizes, and the large sizes are more efficient. The ease and simplicity of installation is also a gain for the two-phase arrangement.

A New System.

In considering the marked advantages of the two-phase system for distribution and of the two-phase system for transmission, it occurred to me that a combination of the two systems might secure the advantages of both in a combined system, and I have worked out a simple and effective method of accomplishing this

Digitized by Google

result. It is well known that if two E.M.F.'s differing in phase be connected in series, the resulting E.M.F. will in general differ in value and in phase from either of its components. If two E.M.F.'s differing in phase 90deg. be connected in series, the resultant E.M.F. is represented in direction and magnitude by the hypothenuse of a right angle triangle, of which the two sides are the two com-

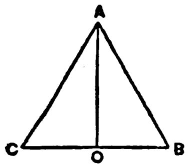


Fig. 6.

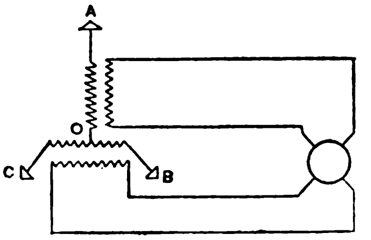

Fig. 7.

ponent E.M.F.'s. Thus in Fig. 6, if A O and O B are two E.M.F.'s at right angles, and these E.M.F.'s be connected in series, the resultant is the line A B, of different phase from either of the components. It is a simple matter to so proportion the components that O B is equal to one-half of A B, as shown in the diagram. In a similar manner it is readily seen that the same E.M.F., O A, may be combined with O C, which differs from it by 90 deg. (but is

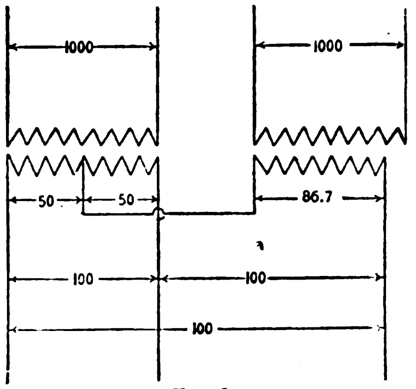

Fig. 8.

equal and opposite to O B) in such a way as to give A C equal to A B, but differing in direction. B O and O C added together give B C. The E.M.F., B C, may, therefore, be combined with the E.M.F., A O, at right angles to it in such a way as to give additional E.M.F.'s, A B and C A, which, in connection with B C, give three equal E.M.F.'s 120 deg. apart. This is the relation of E.M.F's in the three-phase system.

1,000 volts and on one secondary 100 volts and on the other 78 volts, then the E.M.F. measured between any two secondary terminals will be 100 volts. This three-phase circuit is adapted for operating three-phase motors. In a system of transmission two-phase currents at the generator may be converted into three-phase currents, as shown in Fig. 9, and the windings may be such that the E.M.F. is raised for transmission. The currents are then transmitted by three phases, effecting economy in copper. At the other end of the line a similar arrangement of transformers may be used for converting from the three-phase to the two-phase system. The two-phase currents may then be used for the operation of two-phase motors or the circuits may be independently loaded with lamps, or otherwise. If lamps be placed on the transformer which supplies directly from its two terminals the transmission is directly from the generator without affecting in any way the

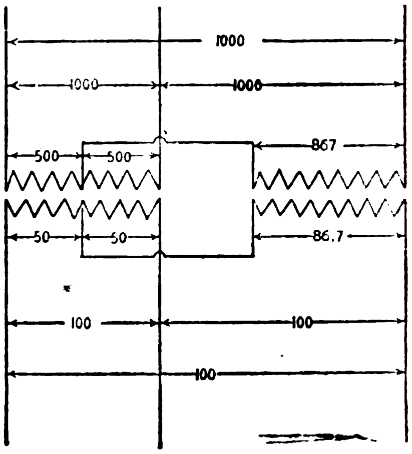

Fig. 10.

other circuit, as the generator terminals are connected directly to the first primaries, and the secondaries of the raising transformer are connected directly to the primaries of the lowering transformer and the current from this is taken directly to the load. On the other hand, if the other circuit be loaded the action here will also be on its own generator circuit without affecting the first. The current from the raising transformer in this circuit passes to the middle of the secondary of the other transformer, where it divides and flows in parallel through the two parts of the coil and two of the lines. As one-half of the current flows through each part of the secondary coil in opposite directions, the self-induction is completely neutralised and the transformers in this circuit are independent of the operation of the other circuit. It is to be noted that under this condition the line E.M.F. delivered by this transformer is only 87 per cent. of that delivered by the first transformer. The lower E.M.F., however, is compensated for by the fact that

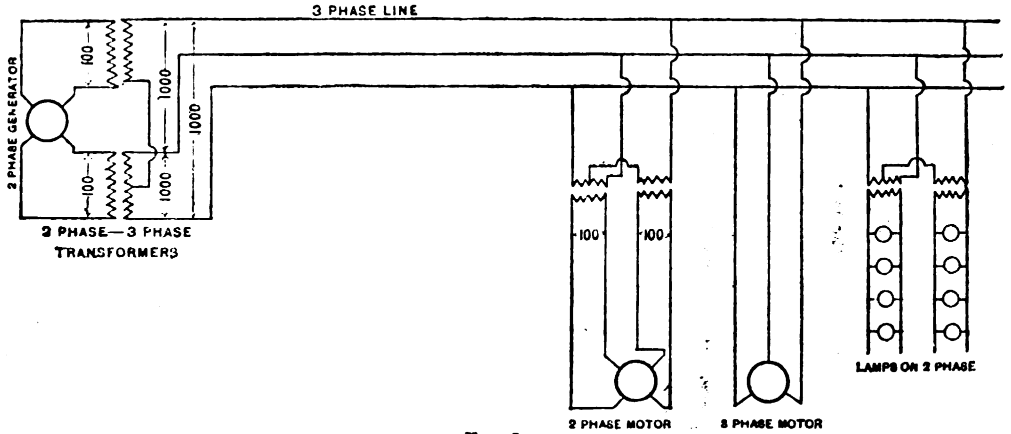

Fig. 9.

The application of this arrangement to transformers is illustrated in the accompanying Figs. 7 and 8. The primaries of two transformers are connected to a generator giving two-phase current. The secondary E.M.F.'s, therefore, differ 90 degrees. One secondary is made equal to 100 turns and a loop is brought out at its middle point giving 50 turns at each side. The second secondary has 87 turns, which is approximately equal to 50 multiplied by the square root of 3. One end of the secondary circuit is connected with the middle point of the secondary of the first transformer, as shown, and the three free terminals will then deliver E.M.F.'s differing in phase 120deg. If the E.M.F. on each primary be

the current on one side is passed through two of the lines in parallel, thus reducing the resistance of the circuit, and compensating for the slightly lower E.M.F.

The effect upon the regulation of the generator when two-phase circuits at the end of a three-phase transmission line are independently loaded is found, both by theory and test, to be the same that prevails when the load is placed directly upon the corresponding circuit of the generator. A modification of this system is found in the arrangement where the three-phase current is produced in the generator and transmitted over three wires to the reducing transformers. These transformers may be arranged

Digitized by Google

as described for producing two phases. Loads may be placed upon either of the two-phase circuits and practically the same regulation in the generator will result that would have resulted if the generator itself had been wound for two phases and one of these circuits loaded. In this way it is possible to place a lighting load upon a three-phase generator in two instead of three units and to avoid the bad regulation in the generator due to unequal loading.

A similar arrangement of two transformers may be used for converting three phases of one potential into three phases of another potential. This arrangement is shown in the accompanying Fig. 10.

The efficiency of two transformers arranged for converting from two-phase to three-phase is reduced below that when working independently on ordinary loads by an insignificant amount. If the efficiency in ordinary working is, say, 97·5 per cent. it would be reduced to 97·4 per cent. in converting from one number of phases to the other.

The Tesla polyphase system in which the largest electrical enterprises are seeking a realisation, adapts itself with marvellous facility not only to all branches of electrical industry, but also by the transformation of its phases to the utilisation of three phases for gaining the highest economy in transmission, and of two phases for securing the maximum advantages in distribution.

DISCUSSION.

Prof. FORBES said he would like to say a few words simply to express the admiration he was sure everyone had felt for the great ingenuity which Mr. Scott had displayed in working out that beautiful arrangement of a combination of the two-phase and three-phase systems together. They must all admit that it was an extremely beautiful idea and appeared on the face of it to be a feasible method. He did not appreciate so much as Mr. Scott seemed to do the superior advantages of the three-phase system for transmission over long distances. The two systems, so far as they could find out in practice, as to their economy, &c., had little advantage one over the other. If the opinion be right that the three-phase system had a distinct advantage over the two-phase than such a scheme as Mr. Scott's ought to prove of great value. He particularly thanked Mr. Scott for the diagram, which showed the inductive electromotive force in volts per ampere per thousand alternations per thousand feet of circuit at different distances between circuits. With that Paper of Mr. Scott's, in conjunction with those which have been written by Mr. Kennelly on the same subject, any engineer had got before him all that was required for calculating the effects of self-induction and capacity upon the circuit. A little more had been done, however, and that was the effect of resonance. Mr. Scott had spoken of the interference of separate circuits upon each other. If he had considered the question of two different circuits, one circuit being a quarter of a period behind the other, then they had a very serious interference. It was most important in a large station where the polyphase system was employed to consider most carefully the arrangement of the conductors. This interference between the two circuits was of very great importance, far more important than the self-induction of one of the circuits upon itself. The lower the frequency the less the trouble from this cause, and hence the adoption of 20 periods per second at Niagara.

Prof. H. A. ROWLAND said that, so far as he could see, Mr. Scott's invention was one of the finest things that had come out in recent years. Very few of them expected that they would be soon able to transform a two-phase system into a three-phase, or any number of phases. The paper marked an era in the science of the polyphase systems. He had himself been working on a paper covering the same points, but his method, though a little broader, was not in any way so practical and simple as that of Mr. Scott's. By his method he could change the period of the current at the same time that the number of phases was changed. Although he quite agreed with Prof. Forbes that a low period was excellent in many respects, he was not able to agree with him as to the exact figures.

Mr. T. SPENCER inquired how Mr. Scott would apply that load factor when the load was distributed along the line, so that one could get an accurate idea of the size of the conductor or percentage of drop in the line.

Mr. SCOTT replied that in that case the problem became more complicated. It would be necessary then to take each part of the circuit and calculate the amount of electromotive force in it, and so on, for each part of the circuit. In practice, however, the counter electromotive force in primary circuits of one or two thousand volts extended over a small area—a mile or so—and with ordinary currents, up to one hundred amperes, was not such as to cause effects of very great practical importance. That was shown from the fact that in the circuits ordinarily operated these effects had not been very prominent. They had not interfered with the working of central stations of pretty large capacity, and the fact was fully demonstrated at the World's Fair Westinghouse incandescent lighting plant, which had been the largest ever installed. In general, the inductive drop in circuits for incandescent lighting was only a small percentage of the ohmic drop; and it was an extreme case when the drop due to induction equalled the drop due to the resistance of the conductor. He agreed with Prof. Forbes on the great value of Mr. Kennelly's Paper. In ordinary working, however, capacity would have very little effect. It was only when they got up to very high voltages or very low lines that the effect of capacity would enter in a marked degree. The so-called skin resistance, or increase of resistance of the conductor, due to the un-uniform distribution of electric currents in ordinary working might be very largely neglected.

Mr. L. B. STILLWELL complimented the Association in having had such a valuable Paper brought before it. He claimed that the plans at Niagara Falls were substantially those laid out by Mr. Tesla several years ago, and referred to the statement of the Westinghouse Company's position in the matter published in the *Electrical Engineer* of January 10, 1894. He also referred to the Westinghouse plant at the World's Fair as exemplifying the general type of the system adopted at Niagara.

ON PARALLEL WORKING, WITH SPECIAL REFERENCE TO LONG LINES.

The following is an abstract of the concluding discussion on Mr. Mordey's Paper, which took place at the Institution of Electrical Engineers on Thursday evening last week. Speakers whose remarks are prefaced by an asterisk have returned their proofs revised.

*Major-Gen. WEBBER said there was one matter which seemed to him to have been left out of the paper, and he thought it was to be regretted. If Mr. Mordey had been able to give them information on the condition of the parallel running which was going on, and which had been going on for a considerable time, under circumstances similar to those which he had described, the data might have been more interesting than those which had been given. They all knew that for two or three years Mordey-Victoria current alternators had been guaranteed to work in parallel with any other dynamo of the same make, irrespective of size. It was not so well known that for a considerable time the City Company had been running in parallel not only two Mordey-Victoria machines, but also one of that make and a Thomson-Houston machine of different size and capacity, supplied and fixed by Messrs. Laing, Wharton and Down, at the station known as the City of London Electric Lighting Company's Pioneer station at Wool Quay, which was close upon 2,500 yards away from their Bankside station on the Surrey side of the river. These machines differed not only essentially in construction, but also in the motors driving them. The Mordey-Victoria was a 100-kilowatt machine, driven by a Brush vertical inverted engine, the speed of which was about 167 revolutions, whilst the Laing, Wharton and Down, Thomson-Houston high-tension composite-field automatic self-regulating alternate-current dynamo had a capacity of 120 kilowatts, was driven by Marshall's engines with a speed of about 170 revolutions. These two machines were both serving the primary circuits of a transformer station in one bank of transformers. He hoped that the facilities obtained from the City Company for a laboratory experiment, as it might be termed, might also be given to Mr. Mordey in connection with this extremely exceptional circumstance which had been going on now for a twelvemonth, and so far as he was aware with success. He might mention that the original frequency of those two dynamos was different: that of the Mordey-Victoria was 100, and that of the Thomson-Houston 130.

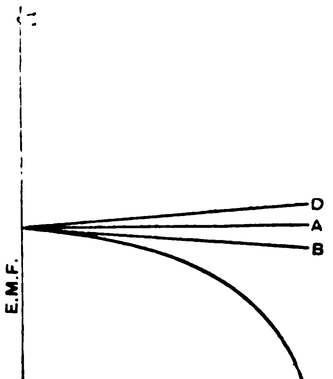
*Capt. SANKEY said he would like to have an opportunity of confirming Mr. Mordey as to the ease with which Mordey alternators had been kept in parallel at Thames Ditton. There was not the slightest difficulty in getting them into step, nor was there any sign of their trying to get out of step, except when a brake having been put on the fly-wheel of one of the sets the speed of both sets was reduced to 25 revolutions from a speed of 500. Then they broke away; the set that had not the brake on went up to about 500, and the other, of course, remained at 25 until the plank used as a brake was removed. As regards the pulsation of the light in the Sunbeam lamps, he was inclined to think that it was due to oscillations in the load on the engines synchronising with the time period of the governors. He did not think it was due to hunting of the governors. The card shown in Mr. Mordey's Paper would, no doubt, be produced if the governor had been hunting, but it would also be produced if the governor were sensitive enough to follow up rapid changes of load. To put the matter beyond doubt he took some cards that morning. First of all he took a diagram holding the pencil down for half a minute, with a perfectly steady load of 240 volts, 340 amperes at 372 revolutions. The diagram was a thin line. Then the load was gradually changed by means of a shunt resistance, backwards and forwards from 240 to 234 volts, and from 350 to 240 amperes, and the card produced was indentical with the one in Mr. Mordey's Paper. The governor was then put out of adjustment so as to hunt, and the card produced was identical with the one due to a changing load. Having gone so far he thought he would like to know how sensitive the governor was, and, therefore, after readjusting the governor, he changed the load 10 times a minute, and the card produced was the same as that in Mr. Mordey's Paper. He then changed the load 30 and finally 192 times a minute, and even in the last case there was a distinct fluctuation on the card, showing that the governor was sensitive enough to follow these extremely rapid changes of load. He had measured the resistance of one of the Sunbeam lamps, it was 35 ohms cold, and it dropped to 17 with 4·7 amperes going through it, which just over-incandesced it. He was not present at the last meeting, but he understood that Mr. Raworth said the whole of this fluctuation was purely a mechanical effect due to hunting of the governors, and that so long as there was friction there must be hunting in governors. Now, it was quite certain there were governors that did not hunt, and it was also equally certain that those governors must have some amount of friction in them. The fact was it depended upon where the friction was, more than upon the amount. He was prepared, if Mr. Mordey would send down a couple of 30 kilowatt alternators to Thames-Ditton, to have them coupled up to two Willans' engines, and experiments might be tried until this matter was thoroughly threshed out.

Mr. MITCHELL read a communication from Prof. Forbes giving a mathematical examination of the parallel working of alternators having no self-induction.

Digitized by Google

*Prof. AYRTON said at the last meeting the discussion seemed to turn upon methods of synchronising alternators, and he would say a word or two upon that subject. The ordinary elaborate method of synchronising alternators was really wholly unnecessary, if only electrical engineers would condescend to deal with the high-pressure circuit of their own alternators instead of always requiring to measure on the low-pressure circuit, and if they would also use electrostatic instruments rather than electromagnetic. Suppose they had two alternators which had to be synchronised: one of them, if they liked, was already attached to the omnibus mains supplying currents, and the other one had to be so attached. Then—as Mr. Mather and he proposed—let them join one terminal of each of the alternators together through a resistance, say, of 20 megohms (the very finest pencil line drawn on a piece of ebonite would do), and then connect the other terminals to any electrostatic voltmeter they liked—and he was using the word now in the most comprehensive form: an electroscope, a vacuum tube, anything which electrostatically indicated high difference of potentials. Imagine, for instance, an electroscope; they did not want gold leaves, tinfoil leaves would do, a foot-and-a-half long if they liked, the leaves being attached to one of the alternators and the outside case to the other. Then as one dynamo was speeded up the leaves would begin to oscillate backwards and forwards very rapidly, then more and more slowly, and finally, when they came together, the machines were exactly in step. They thus had an arrangement far more dead-beat than a glow-lamp; the luminosity remained for a sensible time in a glow-lamp. The apparatus was cheap—they might make it for a few shillings—and might be as large as they liked; they wanted no scale, no actual calibration; it might be as wrong as they liked looked at from the point of view of an accurate electrostatic voltmeter, and no specially doubly-wound transformer was needed with this direct method of synchronising. What they wanted was simply a thing giving a big divergence for 4,000 volts, and no divergence for zero P.D. They had thus a perfectly cheap method of synchronising dynamos, which did not need being metalically connected together, and there was no fear of one dynamo damaging the other. It was so simple that he should imagine it must have been tried, and, therefore, he should be glad to hear what was the experience of trying such a method. They had used it themselves in their laboratory with perfect success, but not with such large leaves as he had suggested.

Mr. W. M. MORDEY, in replying to the discussion, said his colleague, Mr. Raworth, opened the discussion and spoke of the question of pulsation. Mr. Raworth was under the disadvantage of not having read the Paper beforehand. He (Mr. Mordey) thought the pulsations might have been entirely mechanical, but it might also



have been electrical, as he had explained. But, for his part, he stopped at the pulleys of the dynamo, and he must leave Mr. Raworth and Capt. Sankey to settle whether governors could be made which did not hunt, or whether governors must hunt. Mr. Sparks followed Mr. Raworth, and emphasised the need for steady turning in engines driving alternators in parallel working. Mr. Kapp spoke at considerable length on the spur-wheel analogy. He (the speaker) was quite aware that all analogies must fail somewhere. All the same, he did not quite agree with Mr. Kapp's conclusions. Mr. Kapp argued in favour of spur gearing with yielding teeth. Prof. Thompson took the view which he (Mr. Mordey) had taken, in favour of the flexible teeth being weak teeth. Mr. Kapp interrupted, and said, "Not if you regulate the fields." That was to say, if the synchronism was going to give way, if the machines were likely to get out of step, then they must adjust the fields. Of course, that was really the whole question; it was a question between good regulation and bad. He quite agreed with what Prof. Thompson said, that the flexible tooth was really a weak tooth. A magnetic field that was twisted out of shape and pulled round by an armature must necessarily mean a weakened effect. Mr. Kapp said, "Yes; but you can avoid that by adjusting the field when the weakening is taking place." Unfortunately they could not always do that. In trying to make these analogies clear he pointed out that whilst an engine was going over the dead centre, and another engine was taking steam and accelerating a little, there was a tendency to a difference of speed which must be counteracted by very rapid interchange of power between the two machines. That meant that at each stroke of the engine, or perhaps twice at each stroke, or oftener, there was a weakening of the teeth taking place. Now, Mr. Kapp would, of course, acknowledge that he could not possibly regulate for that. Therefore he (Mr. Mordey) argued in favour of machines being designed which did not require this regulation, because they complied with what ought to be one of the principal conditions necessary to the good working of central station dynamos; he meant they had a constant electromotive force, or nearly constant. If they took a machine, such as Mr. Kapp thought was best, and excited it, say for full electromotive force, with no load, and then suddenly switched the load on, the volts would go right down. Let the abscissæ represent load and the ordinates electromotive force, then of course the perfect machine for parallel working for alternate current distribution would be one that gave a perfectly straight line A. Machines were made to give a perfectly straight line by hand regulation as a rule, sometimes by various methods of automatic regulation. In order to get it with any machine they had to increase the excitation of the field as the load came on. They might have to increase it a great deal or very little. In the case of a powerful synchroniser, if they did not increase the excitation at all and put the whole load on gradually, the line would fall a little bit, as shown by B. Taking the machine that Mr. Kapp advocated, the line would become a dropping curve, like C. Suppose they increased the excitation of the two machines to compensate for the drop: suppose that the fuses went: they then had no possible opportunity of regulating the fields. It was an instantaneous matter, and the field had just to take its chance. Well, the machine with the strong teeth would rise in volts about as much as it fell, as shown by line D. That was to say it might be about 4 per cent. each way on his (Mr. Mordey's) machine. Now, taking the machine, a type of machine which had been very successful in many ways, designed by Mr. Kapp and many engineers in different parts of the world. When the fuses went what happened? Well, the volts went somewhere up to E. They might say this large electromotive force was not on the mains, and therefore did not matter. Still, it was a risky thing. Imagine the electromotive force somewhere up there, and the engine running unsteadily, the governor sticking, or hunting—something of that kind happening. It had got pulsations of power alternately, the electromotive force was alternating between nothing whenever it tried to take a large current, and the point E up there whenever by reason of its not having steam the load was transferred to the other machine, so it was not merely in the parallel working qualities of the machines that the question was of importance. He was glad to have the information as to the resistance of the Sunbeam lamp in the Thames Ditton experiments. The change of resistance between the incandescent state and the cold state was even greater than he supposed. He thought that went a long way to support the contention he raised, that this marked change in the resistance joining the machines had to do with the pulsations.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March* 16, 1894.

Electrical Units.—At the meeting of the American Institute of Electrical Engineers on March 21st, the proposed names for the magnetic C.G.S. units will be brought up for provisional adoption. These, as your readers are doubtless aware, are the terms "Gilbert," "Weber," "Oersted," and "Gauss" for the C.G.S. units of magnetomotive force, magnetic flux, reluctance and flux density, respectively. It is urged that there is a practical necessity for the adoption of names for the magnetic units, and that their C.G.S. values are practical values. Objection has been made to the names proposed that they are not in conformity with the Greek names "erg" and "dyne" in the C.G.S. system, and are at variance with the practical system of other units in use as to their dimensions.

Personal.—Mr. O. T. Crosby, Manager of the street railway department of the General Electric Company will resign that position on May 1st to join the well-known firm of J. H. White and Co., constructing engineers. Mr. H. P. Parshall will continue with the General Electric Company as consulting engineer and will shortly sail for Europe on professional business.

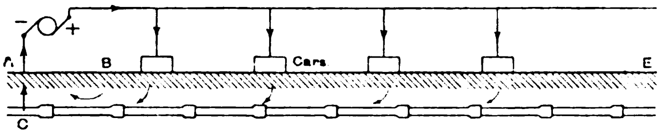
CORRESPONDENCE.

THE POLARITY OF THE EARTH RETURN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The discussion of the Board of Trade Draft Electric Traction Regulations having shown the considerable amount of importance given by the interested bodies to the subject of connecting the uninsulated return of traction circuits to *the negative* terminal of the generator, and some criticism having been directed some time ago against the arrangement adopted at the Marseilles Electric Tramway, where, for trial, I gave the *positive* polarity to the earth line, I ask for some space in your valuable paper to submit you the results of my personal experience and investigations on this subject.

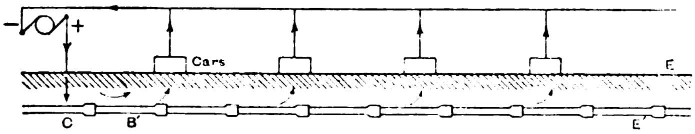
In a given plant, the track line of which is connected at one time to the negative and at another to the positive terminal of the generator, all other things being equal, the sum of all leakage earth currents will be exactly the same in both cases, depending only on the difference of potential between the point connected to the generator, and the other points along the track.



A gas or water pipe parallel to the track, and extending along its entire length, will become a conductor to these leakage currents, and, irrespective of the polarity of the track, the current density in this pipe will be greatest near the point of connection to the generator.

In case I., the track line being negative, the leakage currents leave the track at any points located between the end of line E, and a point B, generally very close to A, enter the pipe and leave it all together at C, in order to reach A through earth. The outflow of all elementary leakage currents being concentrated on C, the current-density at this point may become large enough to produce considerable electrolytic corrosion of the pipe in a very short time.

In case II. the track line being positive, the location of the leakage-currents is evidently the same, but they flow in opposite directions. The current inflow will be concentrated at point C, and no electrolytic action occurs there. The leakage currents then *leave* the pipe at any points between B′ and E′,



but the outflow being in this case divided over a very large surface of pipe the density at any point will not be large enough to produce any appreciable action on the pipe, unless after a relatively long time.

This assertion is fully confirmed by the results of a two years' working with case II. at the Marseilles Tramway, where no difficulty whatever has been found with electrolysis, although the station output often reaches as high as 350 to 400 amperes. The danger of this arrangement, however, lies in the fact that some special conditions, moist soil, branch pipes very close to the track, &c., may favour the concentration of current outflow to points that can only be detected by an accident itself, and the protection of which is, therefore, very difficult. With the *negative* terminal to earth, the danger being always concentrated principally at point C, protection of this point may be easily attained by a good, reliable, and *well-insulated* metallic connection to the negative terminal of the generator. Such a connection, with a current indicator in its circuit, and together with the regular "Board of Trade" earth connections, will prove very useful, as by it means a very reliable control over the return and the electrolytic dangers may be obtained.—Yours, &c.,

Marseilles, March 28, 1894. H. DUBS.

LEGAL INTELLIGENCE.

Dickenson v. Ronald A. Scott.

At the Stockton County Court last week, before Judge Turner, Mr. Thomas Dickinson, building contractor, of Middlesbrough, sued Ronald A. Scott, described as an electrical engineer and patentee, of Acton Hill, Middlesex, for £20. 10s. for work done.

The case for the plaintiff was that in May last the defendant arranged with his agent, Mr. W. C. Folchard, of Stockton, to have two displays at Middlesbrough of his patent electrical apparatus for advertising on the clouds with a view to selling the patent rights for the six northern counties to a syndicate, which Mr. Folchard and Mr. Fred Forster were to get up. The plaintiff put up the staging, &c., for the displays, and assisted to erect the machine and also take it down, but neither Mr. Folchard nor the defendant had paid him. An offer of £4,000 was made for the patent rights, and Mr. Folchard was to have 5 per cent. commission, but Captain Scott wanted, in addition, a royalty of £4 per lamp per annum, and the negotiations fell through.

The defence was that Mr. Folchard was liable, and the defendant, on a counter claim, sought to recover £50 damages for loss of profits arising from the wrongful detention of the machine by the plaintiff.

The JUDGE, after a long hearing, found for the plaintiff for £12 and costs, and against Mr. Ronald A. Scott on his counter-claim.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Corporation of Edinburgh require tenders for the erection of the buildings, &c., of their central electric light station at Torphichen-street. Tenders have to be sent in to the Burgh Engineer, City Chambers, Edinburgh, not later than Wednesday next.

——— The proprietors of the Rhyl Pier and Pavilion invite tenders for lighting the same by electricity. Particulars can be obtained at 3, Bradshaw-street, Shudehill.

——— The Baden State Railway Authorities invite tenders for the supply and erection of plant, on the continuous-current system, for the lighting of the Carlsruhe Railway Station. Tenders have to be in by May 1st.

TENDERS ACCEPTED.—The tender of Messrs. Drew, Beard, Romson, and Parks, of 71A, Queen Victoria-street, E.C., has been accepted for the sum of £846. 18s. 10d., for the supply of steel lattice girders, rolled joists, cover plates, bolts, rivets, tie-rods, coupling-boxes, and rail struts, two traverse tables, and creosoted deal rail packings, for the Brighton and Rottingdean Seashore Electric Tramroad Company.

APPOINTMENTS.—Mr. A. B. Blackburn, M.I.C.E. (late with Messrs. Mather and Platt, Limited) has been appointed Chief Engineer of the Electric Construction Company (Limited).

——— Mr. L. Le Gros Horne has been appointed Electric Light and Telegraph Superintendent to the Great North of Scotland Railway Company, *vice* Mr. P. M. Barnett.

——— Mr. Joseph Shepherd has been appointed electrician to the Bolton Corporation, at a salary of £110 per annum.

——— The Dewsbury Board of Guardians, having considered the applications (22 in number) received for the post of "consulting electrical engineer," and to superintend the erection of the electric lighting plant at the workhouse, have decided to appoint Mr. Arnold Greener, of Dewsbury, at a salary of 30s. per week, provided the Dewsbury Corporation have no objection to his holding the appointment, or failing Mr. Greener, then Mr. Ernest Marples, of Liverpool.

LIQUIDATIONS.—The petition of General Sir R. J. Meade for the winding up of Elmore's Foreign and Colonial Copper Depositing Company (Limited) came before Mr. Justice Vaughan Williams in the Chancery Division on Wednesday. Counsel stated that the petition came up on the last day of last sitting, and it stood over till now. In the interval the petitioner had died, and the executors had not proved the will, and under these circumstances it was asked that it should stand adjourned for a month, to which his Lordship agreed.

——— A petition by shareholders for compulsorily winding up the South Staffordshire Tramways Company (Limited) came on Wednesday before Mr. Justice Vaughan Williams. It was directed to stand over till Wednesday next for the filing of further evidence in support of the petition.

DISSOLUTION OF PARTNERSHIP.—The partnership hitherto existing between William Winstanley Strode, Edward Phillip Williams, and George Edward Cockburn, of 67, St. Paul's Churchyard, London, gas and electric engineers, has been dissolved. The debts of the old firm will be paid by Mr. W. W. Strode.

Digitized by Google

"ANTI-SULPHURIC ENAMEL."—This material is being used in the accumulator rooms of the Carnaby-street Electric Lighting Station of the Pall Mall Company, to protect the wood and metal work from the action of the fumes and spray from the batteries.

LOCAL GOVERNMENT ACT, 1894.—A pamphlet abstract of the new Local Government Act (being a reprint from the *Local Government Journal*) is issued by S. Edgecumbe Rogers, Dorset House, Dorset-street, London, E.C., price one penny.

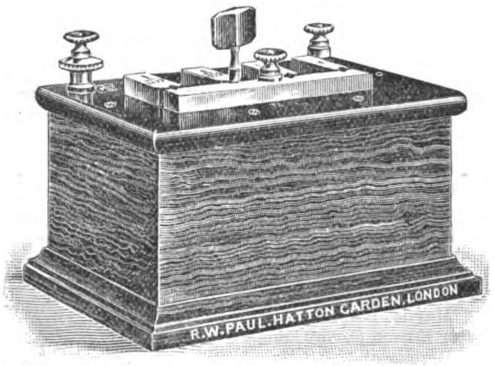
WORKS PREMISES.—The sale by auction, by Messrs. G. A. Wilkinson and Son, of the valuable freehold property, Cadby Hall, Hammersmith-road, West Kensington, recently in the occupation of Messrs. Woodhouse and Rawson United (Limited), is announced for Monday, the 23rd inst., at 2 o'clock, at the Mart, Tokenhouse-yard, London, E.C. Further particulars will be found in our advertisement columns.

ARTISTIC FITTINGS.—Messrs. Lea, Sons and Co. have just completed a set of elaborate electric light fittings for Lord Armstrong, of Cragside, Rothbury, N.B., consisting of two 17-light electroliers in oxydised silver and gilt, for the saloon and picture gallery, the ornamentation in beaten scroll and foliated work; a large octagonal shade light, 3ft. in diameter, the framework of dead bright steel in perforated and beaten panels, representing the rose, shamrock, and thistle; fittings for Lady Armstrong's boudoir, in gilt chased and beaten work, carrying a glass bowl, in which electric lamps are placed; and fittings for the studies, in black iron ribbon scroll work, with inverted opal shades.

TURRET LATHES AND SCREW MACHINES.—Mr. H. F. L. Orcutt, agent for Messrs. L. Loewe and Co., of Berlin, sends us a newly-issued illustrated sheet of turret lathes, screw and slotting machines, drills, &c.

DANISH PATENT LAW.—A new patent law for Denmark has been passed by both Chambers of the Legislature, and will probably become law in the course of a few days. The alteration effected by the new law assimilates Danish practice to that of Germany, Norway, and Sweden. Protection is given from date of filing application, the duration of the patent is 15 years, the importation of patented articles is prohibited, the examination as to novelty is prior to the grant, and opposition to the grant by parties interested is permitted. The new law is intended to come into operation about the middle of June.

THE AYRTON-MATHER UNIVERSAL SHUNT BOX.—On another page we give the Paper read by Prof. Ayrton and Mr. Mather on the 29th ult. before the Institution of Electrical Engineers on



"The Universal Shunt Box," and we give above an illustration of the box, which is manufactured by Mr. R. W. Paul, of 44, Hatton-garden, E C.

CHLORIDE ACCUMULATORS.—We have received from the Chloride Electrical Storage Syndicate (Limited) a well got-up catalogue and price list of chloride batteries. The pamphlet contains a description of the batteries, and details the advantages claimed from their use for traction purposes.

INTERNATIONAL ELECTRIC SUBWAY COMPANY (LIMITED).—This Company have just issued in convenient form a pamphlet describing the Johnstone system of conduits, the patents for which are owned by the Company. A number of illustrations and drawings show the method of laying the conduits. In the pamphlet is a price list, extracts from press notices, and favourable testimonials from large users of the Company's conduits.

MESSRS. DRAKE AND GORHAM.—This firm have obtained the contract for lighting two of the large new houses in Melbury-road, Kensington, with 115 incandescents, and are putting in a steam-engine plant for the lighting of the country house of Le Court for Mr. Heath Harrison.

"CLUBS."—This is the title given by Mr. E. C. Austen Leigh to a handy list of clubs frequented by the English in all parts of the world. This is the second year of publication, and the author has now been able to make up the total number to over 1,000 clubs in London, the provinces, and abroad. The price of the book, which is published by Messrs. Spottiswoode and Co., is 1s.

ACCRINGTON.—The Local and Parliamentary Committee of the Corporation have recommended that plant be put down for supplying electric current equivalent to 4,000 8-c.p., and that provision be made for extensions. It is further recommended that steam be selected as the motive power.

ABERDEEN.—The Gas Committee of the Corporation recommend that in future the committee be renamed the Gas and Electric Lighting Committee. Prof. Kennedy has appointed Mr. G. G. Clark as second engineer at the electric lighting station. At the last meeting the Gas Committee authorised the purchase of 50 electricity meters at an estimated cost of £320.

BEDFORD.—At the last meeting of the Town Council, the Mayor read a letter from the Board of Trade regarding the objections made by the Council to the application of the Bedford Electric Lighting Company for a Provisional Order, and suggested that a deputation representing all parties should appear before them to discuss the matter. It was agreed to appoint a deputation from the Council to wait upon the Board of Trade. The Town Council have obtained a Provisional Order, but so far have done nothing further in the matter, and the object of the Bedford Electric Lighting Company is to ask the Board of Trade to transfer the Order to them, but this proposal meets with the strong opposition of the local authorities.

BELFAST.—At a meeting of the Electric Lighting Committee, held on Tuesday, applications for the appointment of a resident electrical engineer were considered. There were nearly 60 applications, which were reduced to 10, and which will be further reduced to six, from which the Council will ultimately select.

BIRKENHEAD.—It has been decided to purchase a piece of land, 3,152½ square yards in extent, for the central lighting station, at a cost of £1,576. This will provide more room than is at present required, and will therefore allow for subsequent extensions to be made.

BRIDGEND.—The Local Chamber of Trade has decided to take legal advice as to the legality of the action of the Local Board in defraying the cost of the electric lighting Provisional Order out of the public rates.

BRISTOL.—Notwithstanding the local authorities of Bristol, St. George, and Kingswood, have given their sanction to the scheme for electric traction, it is stated that opposition is to be offered by several tradesmen in West-street, Kingswood, the grounds of opposition being the narrowness of thoroughfare. The tramways company are actively proceeding with the necessary plans and specifications, in order to be ready to commence work as soon as Royal assent is given to their bill. The threatened opposition comes as a surprise, and an effort is to be made by the influential local committee which originally supported the scheme to induce the opponents to re-consider their position.

CHATHAM.—A meeting of the Town Council was held last week, and, on the proposition of the Mayor, it was decided to ascertain the cost of constructing a tramway from the Luton Arch to the top of Star Hill, to be driven by electricity. If the Council decide to construct this tramway, the Chatham and Rochester Company are to be asked to supply the Corporation with current, and to prepare an estimate of probable cost.

CHELTENHAM.—With regard to the tenders received and accepted by the Town Council for electric lighting plant and machinery, it is noticeable that the amounts of the tenders are remarkably equal, especially when the highest and lowest tenders are eliminated. The second highest tender for the whole of the plant is £4,610, and the second lowest £4,100. As announced in our last issue, the tenders of Messrs. Siemens Bros. and Co. and Messrs. Galloways (Limited) have been finally accepted. The following is a complete list of the tenders :—

	For the whole.	For A.		For B.			For C.
	£	£	s.	£	s.	d.	£
Laing, Wharton and Down	4,964	380	0	4,002	0	0	682
Siemens Bros. and Co. (1)	4,360	365	0	3,450	0	0	590
Ditto (2)	4,610	365	0	*3,695	0	0	*590
John Fowler and Co.	4,500	377	0	3,612	0	0	575
Johnson and Phillips	4,307	345	0	3,280	0	0	682
Crompton and Co. (1)	4,100	430	0	3,060	0	0	660
Ditto (2)	4,125	430	0	3,100	0	0	660
Ditto (3)	4,180	430	0	3,165	0	0	660
Ditto (4)	4,170	430	0	3,160	0	0	660
Ditto (5)	4,470	430	0	3,460	0	0	660
Brush Company	3,840	340	0	3,006	0	0	521
Galloways	—	*438	15	—			—
Spurr, Inman and Co.	—	340	0	—			—
Electric Construction Company.	—	—		3,400	0	0	—
Mather and Platt	—	—		3,255	10	6	—
McLaren	—	—		3,322	10	0	—
Willans	—	—		3,963	0	0	—

* Accepted tenders. The engines in the successful tenders are Willans' direct driving.

A, boilers only ; B, engines and alternators ; C, condensing plant.

Digitized by Google

Messrs. Laing, Wharton and Down's tender was for Browett and Lindley engines, as were also the tenders of Messrs. Johnson and Phillips (belt driving) and Crompton and Co. No. 1 (rope driving); Messrs. Siemens Brothers and Co.'s tender No. 1 was for Belliss engines (direct driving), as were also Messrs. Crompton and Co.'s tenders No. 3 (rope driving) and 4 (direct driving); Messrs. John Fowler and Co.'s tender was for Fowler engines (rope driving); Messrs. Crompton and Co.'s tender No. 2 for Davey Paxman engines (rope driving), and 5 for Willans' engines (direct driving); and the Brush Company for Brush engines (direct and rope driving).

The Local Government Board has given its sanction to a loan of £16,000 to be borrowed by the Cheltenham Town Council for the purposes of electric lighting, repayable in 25 years, and has further given its consent to the use of part of the site of the Destructor for the electric lighting station.

CHERRYHINTON.—It is proposed to form a company to light the Cherryhinton district by the electric light, and a meeting was held last week to discuss the subject. Lord Russell, who was present, said that the whole of the buildings, plant and machinery, mains and transformers, could be put down for about £2,500 or £3,000. His firm, as contractors to the scheme, were willing to take 50 per cent. of their contract in debentures, provided about £2,000 was subscribed. This sum would provide for about 500 lights, which was as much as they could expect to have taken up for the first few months. The Chairman of the meeting said, that doubtless if it could be shown that customers for the current would be forthcoming, people in Cambridge would assist Cherryhinton in providing the necessary capital. It was decided to adjourn the meeting for inquiries to be made as to the probability of obtaining the necessary capital and other support.

CHURCH LIGHTING.—The officials of the leading cathedrals and churches throughout the country are gradually adopting the electric light, and the authorities of the Methodist Free Church at Blackpool have entrusted Messrs. Maunsell Mercier and Co., of Manchester, to instal the light throughout the church, for the sum of £70, including electroliers. This is the first church in Blackpool to adopt the electric light.

CITY OF LONDON.—The gas standards have now been removed from all the principal thoroughfares, and the public lighting of the City is now almost entirely in the hands of the City of London Electric Lighting Company.

COLCHESTER.—A serious accident happened at the extensive works of Messrs. Davey, Paxman and Co. on Saturday last, causing the death of two of their employés and the injury of a third man, who were engaged in testing a cast-iron oil collector, part of a large plant being manufactured for a refrigerating company, when the massive tube burst. Several remarkable escapes from injury occurred.

COVENTRY.—The City Council have approved the plans for the proposed electric lighting station, with some slight alterations, and the Corporate Seal has been affixed to the contract with Messrs. John Fowler and Co., of Leeds, for the electrical equipment of the station.

DEWSBURY.—The Board of Guardians have decided to erect the necessary buildings and put down plant for lighting the workhouse and cottage homes belonging to the Union by electricity. They will ask for borrowing powers for £2,150 towards the cost. The Electric Lighting Committee having considered the application of the Collier-Marr Company for preparing plans and specifications amounting to £16. 11s., have recommended the offer of £11. 11s. in settlement, without prejudice.

DUBLIN.—At the meeting of the Corporation on Monday the report of the Electric Lighting Committee was taken into consideration, in which it was stated that though the contract for the additional plant was being placed with Messrs. Fowler and Co., an English firm, it had been arranged that the boilers and all other articles should, so far as possible, be made in Dublin. The increased plant was necessary to meet the growing demand for the current. An attempt was made to refer the matter back to the Committee, in order that further tenders might be obtained; but this was defeated by a majority of two; and ultimately it was referred back to the Committee for further consideration without any conditions.

DUNDEE.—A complaint having been made by local tradesmen concerning electricity meters put in by the Corporation, the Police Commission have agreed that Major Cardew, the electrical adviser to the Board of Trade, should make a test, on condition that if the meters are found correct, the consumer shall pay all expenses.

EDINBURGH.—The principal proprietors and tenants of the property in George-street, St. Andrew's-square, Charlotte-street, and the streets leading into these important thoroughfares from Princes-street, have determined to energetically memorialise the Local Authorities to have these streets included in the electric lighting scheme. If this movement is successful a considerable extension of the Council's original scheme will be necessary.

ELECTRIC ORGANS.—Mornington-road Wesleyan Church, Southport, has been furnished with an electric organ, comprising great swell, choir, solo, echo, and pedal organs with couplers, and 53 stops, besides accessories. The first rehearsal took place last week, and proved highly successful.

EXHIBITIONS.—An Exhibition of British Industries is to be held at Earl's Court, London, W., from May to October, the object being to illustrate the various industries of Great Britain, with special reference to the advances made in methods of production and new inventions during recent years. The buildings are to be lighted throughout by electricity, and the exhibits will be divided into seven sections—manufactures, mechanical engineering, machinery and electricity, agricultural, mining and metallurgy, science, and fine arts.

GUILDFORD.—Since the resolution adopted by the Town Council, as previously reported, a meeting has been held, at which a spirit of conciliation was evinced, and the Mayor and Town Clerk have been appointed to discuss with the promoters the possibility of the Council giving its sanction to the application made by the local Company for a Provisional Order, on condition that terms can be arranged so that the Local Authority can take over the Order any time after ten years by giving six months' notice. It is, therefore, more than likely that the present deadlock will be satisfactorily arranged. A motion that the Council undertake to themselves promote an electric lighting scheme in five years time was discussed, but was negatived, it being pointed out that several public works of considerable magnitude were already being undertaken by the Council.

GLASGOW.—The Kelvinside Electricity Company have decided to reduce the price per Board of Trade unit for electric current on and after May 15th next to 6d. This is a reduction of 2d. on the present price, and is 1d. less than the Corporation charge.

HANLEY.—The following is the complete list of tenders received by the Corporation for electric light wiring and fittings to the Corporation buildings:—1. Town Hall, including Victoria Hall. 2. Free Library and Boys' Reading Room. 3. Museum and Technical Schools. 4. Baths. 5. Market Hall and Fish Market. 6. Butchers' Market. 7. Electricity Works. (Mr. Joseph Lobley, Borough Engineer and Surveyor.)

C. A. Hemingway, Richmond	£5,681
Crompton and Co., London	4,925
Charles Smith and Sons, Birmingham	4,159
Laing, Wharton and Down, London	4,152
A. H. Wood, London	4,121
E. M. Evans, Manchester	4,086
Bourne and Grant, London	3,986
Brush Electrical Engineering Company, London	3,980
Paterson and Cooper, London	3,915
W. A. Shaw and Co., Stockport	3,897
Graham and Priddle, London	3,873
R. Barnett and Co., Newcastle	3,865
Sharp and Kent, London	3,859
A. F. Joel and Co., London	3,789
Fowler, Lancaster and Co., Birmingham	3,733
Marryat, Lillywhite, and Co., London	3,726
J. C. Collum and Co., Leicester	3,657
Walsall Electrical Company, Walsall	3,657
Johnson and Phillips, London	3,651
New and Mayne, London	3,651
Manchester Edison Swan Company, Manchester	3,585
Maunsell Mercier and Co., Manchester	3,527
Baxendale and Co., Manchester	3,445
S. H. Heywood, Manchester	3,061
Spagnoletti and Crookes, London (accepted)	3,034

In addition to the above, tenders were received from Messrs. Harry South (London), Joseph Blackburn (Nottingham), J. Defries and Sons (London), Thomas Barton (Blackburn), Lea, Sons and Co. (Shrewsbury), B. Verity and Sons (Manchester), and Donnison, Parmiter and Barber (Manchester), for wiring and fittings to a portion of the buildings, and from Messrs. J. D. F. Andrews and Co., to a different specification. Messrs. Spagnoletti and Crookes' tender has been, by modification of some of the items, reduced to the round figure of £3,000.

HULL.—It has been decided by the Lighting Committee of the Corporation to reduce the charge for electric current from 7d. to 6½d. per unit. A member of the Council pointed out that, with only a small balance on the right side from last year's working, the reduction would probably result in a considerable deficit at the end of the current year, but the Chairman of the Committee replied that last year 75,000 units were sold, and if with the reduced charge the consumption was much increased, as might reasonably be expected, there would be no deficit. As showing the appreciation in which the electric light is held by the leading firms in the district, the following letter was read from Messrs. Thomas Bach and Co.:—"We have now been users of the electric light for thirteen months, and are quite satisfied with it. It has never failed us a second, and not a penny has been expended upon it since its first installation. When it was

Digitized by Google

first put in we had our premises painted and papered, and for the first time find that at the end of the year no outlay is necessary to keep our premises clean and wholesome; our stock is now undamaged, the health of our employés is far better, and danger from fire is minimised, as neither taper nor matches are required." An amendment to reduce the cost to 6d. per unit was lost, and the Committee's proposals adopted. The Committee also decided to recommend that the price of current for power purposes be reduced to 5d. per unit.

LARNE.—The agreement between the Town Commissioners and the liquidator of Messrs. J. E. H. Gordon and Co. for the lighting of the town by electricity for three years has been approved.

LLANELLY.—At a meeting of the Llanelly Local Board a communication was read from the Electrical Installation Company (replying to a letter from the Board), in which the Company stated they hope to complete the agreement to proceed with the electric lighting of Llanelly in a fornight's time. The Board were, however, of opinion that sufficient time had already been given, and on the initiative of Mr. Trubshaw the Board's agreement with the Company was terminated.—*South Wales Daily News.*

MANCHESTER.—The Electric Light Sub-Committee of the City Council having recommended the appointment of Mr. C. H. Wordingham, as resident electrical engineer, at a salary of £500 per annum (as stated in our issue of the 16th ult.), Alderman Sir John Harwood, in reply to an inquiry at the last meeting of the City Council, said that the committee had found the electric light supply was not working with that smoothness which was necessary if they wanted to obtain public confidence, and they had asked Dr. Hopkinson to supply them temporarily with an engineer. Mr. Wordingham came and took charge, and everything had since then worked smoothly. The committee, therefore, proposed to make the appointment a permanent one, which was unanimously confirmed.

NEWCASTLE.—The firm of Rowland Barnett and Co., which has just been registered as a joint-stock company, contemplate considerable extension and development of their present works at Walker Gate.

PLYMOUTH.—The local gas company has incurred the displeasure of the Corporation, and this body has determined to bring about a reduction in the price of gas. The Company have a bill before Parliament to many of the clauses of which the Corporation take severe exception. The Corporation submit that the highest standard price of gas authorised by the Companies Act of 1879, and which it is proposed to re-enact by the present bill, is unsatisfactory, and that this state of affairs is largely due to the very large profits which the Company under its Act has power to divide amongst its shareholders. The Corporation in particular object to the provisions of the bill authorising the gas company to supply electricity for lighting and other purposes in the district. In 1879 the Company applied for these powers, but were unsuccessful. The Corporation are applying for a Provisional Order, which, it is anticipated will be shortly granted.

PORTSMOUTH.—The progress of the electric lighting works is sufficiently forward to justify the Electric Lighting Committee of the Corporation in giving the machinery a trial in about a week's time, and advertisements are to be issued for permanent officials.

ST. PAUL'S CATHEDRAL.—It is stated that it is the intention of the Lord Mayor to call a great meeting, to be held at the Mansion House, London, on May 25th, with the object of raising a quarter of a million of money to carry out the new decorations and other improvements at St. Paul's Cathedral, including the electric light, for which it is proposed to use 200 large candle-power incandescents.

SCARBOROUGH.—At a meeting of the Cliff Bridge Company, at which the Mayor presided, a report was presented from a committee appointed to consider the question of lighting the Spa by electricity. This committee recommended the adoption of the electric light for the theatre only at present, leaving for future consideration the question of its introduction into other portions of the buildings and grounds. The current is to be taken from the local company's mains, but provision is to be made while laying the mains to provide for probable extensions in the near future. The theatre lighting is estimated to cost £300.

SOUTHAMPTON.—At the last meeting of the Harbour Board it was resolved, on the recommendation of the Works Committee, to allow Mr. Kerbey Bowen to place on the Royal pier a charging box for the supply of electric power for launches, subject to the payment of 8d. per unit for current supplied by meter, and a rent of £5 for the charging box. The electrical works at the pier and the quay being near completion, it was also resolved to appoint Mr. J. G. W. Aldridge as consulting electrical engineer for twelve months, with a retaining fee of £10.

STIRLING.—The points of difference between the Town Council and the Caledonian Electric Supply Company are not yet settled. The Electric Lighting Committee have recommended, and the Council agree, to decline to withdraw their opposition to the order of the Company, and have further resolved to request the Board of Trade to withhold their consent to the order, on the ground that the Company now refuse to grant to the Council the terms which had been previously offered.

STRASBURG.—It is reported that the Strasburg tramways are to be converted into electric lines under a concession which extends to 1926.

THEFT.—Thomas Stevenson was charged at the County Court, Belfast, with stealing moneys from his employer, Mr. J. H. Greenhill, of New King-street, Belfast, the amount being made up of small sums taken weekly out of the moneys which the prisoner was given to pay the workmen's wages. Mr. Greenhill was anxious to get back the good character which he had given the prisoner on leaving.

TUNBRIDGE WELLS.—It has been under consideration to put down gas-engine plant in lieu of steam-engine plant for the central station here, but a report from Mr. A. H. Preece, who has advised the Town Council on the subject, recommends that steam plant be put down with a gas engine for the light load, and this recommendation has been adopted, the local gas company being asked to allow a discount of 10 per cent. on the gas used at the station for power purposes. The Electric Lighting Committee have been invited by Sir David Salomons to visit the new City of London electric light buildings when completed, and Sir David also advises the consumption of the town refuse in producing the electric light.

WEYBRIDGE.—The Lighting Inspectors of the Chertsey Rural Sanitary Authority having expressed a desire to renew the contract for lighting the village by electricity, the Authority has sanctioned the proposal. It was pointed out that the lighting company were under a daily penalty for not removing the overhead wires, but the Authority have undertaken not to bring any action in the matter until after September 29, 1895.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by* MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.

APPLICATIONS FOR PATENTS.

March 17, 1894.

5,619. H. BARTELS. London. Improved construction or arrangement of bridge or support for electric wires and in appliances for fixing or holding such wires in place therein.

5,631. E. J. PRESTON and A. B. GILL. London. Improvements in and connected with the electric lighting of trains and other vehicles.

5,637. J. CHAVANNE. London. Improvements in electric accumulators.

5,643. Sir C. S. FORBES and THE DOMESTIC TELEPHONE COMPANY (LIMITED). London. An improved telephone combination.

5,647. A. SCHNELLER and W. J. WISSE. London. Improvements in the manufacture of secondary coils for transformers.

5,650. R. PEARSON. London. A thermometric circuit-closer.

March 19, 1894.

5,690. H. OPPENHEIMER. London. Improvements in connection with microphones.

5,721. C. SMITH. London. New or improved process and apparatus for the electrolytic decomposition of common salt. (G. Jorgensen, Norway).

RECENT FRENCH PATENTS AND CERTIFICATES OF ADDITION.

The following list of French Patents and Certificates of Addition is specially prepared for THE ELECTRICIAN. *A list of these Patents will be given from time to time, and arrangements have been made for supplying MS. Abstracts of the Patent Specifications (with Drawings), of which further particulars will be found in an advertisement on page xv. The advantage of this arrangement is that our readers will be able to obtain the earliest information regarding French Patents, which can be obtained (in most cases) many months earlier than similar information regarding English or American Patents.*

233,105. GOULD & CIE. Automatic hydraulic winding-up apparatus, especially applicable to the Hughes telegraph apparatus. (September 23, 1893.)

233,117. SOCIÉTÉ ANONYME DES ANCIENNES SALINES DOMANIALES DE L'ETAT. Electrolytic diaphragm. (September 29, 1893.)

233,185. RAHNER. Improved armature for dynamos and electric motors. (October 3, 1893.)

233,271. BRUNS. Improvements in indicators specially used in telephone posts and in annunciators. (October 7, 1893.)

233,363. MILLAUD. Automatic commutator for reducing the cost of electric lighting, electro-deposition and all electrical purposes. (October 12, 1893.)

Digitized by Google

233,371. PICARD. System of transformation of alternate currents into continuous currents. (October 13, 1893.)

233,468. CHAUVET. Coin-actuated machine for stereoscopic apparatus. (October 16, 1893.)

233,579. SOCIÉTÉ ANONYME DES ANCIENS ETABLISSEMENTS CAIL. Improvements in cut-outs for high-tension electric conductors; system Cail-Grosselin. (October 23, 1893.)

233,604. ELECTRIC SELECTOR AND SIGNAL COMPANY. Apparatus for choosing and putting in motion mechanism by employing an instrument of electrical transmission called an Electric Selector. (October 24, 1893.)

233,654. PIGANEAU. Improvements in accumulators. (October 26, 1893).

233,719. PÉCOUL. New electric accumulator with porous and oblique troughs. (October 30, 1893.)

233,743. UNIVERSAL ELECTRIC PULL-SOCKET AND SWITCH COMPANY. Improved combined switch and cut-out for electric brackets and pendants. (October 31, 1893.)

233,931. POGNEAUX. New fastening, called "Junius" fastening. (November 13, 1893.)

233,945. DE SEGUNDO AND DERHAM. Electric heating apparatus. (November 9, 1893.)

233,998. KINNIBURGH. Ear-trumpet for telephone receivers. (November 11, 1893.)

234,091. NABER. Voltameter. (November 15, 1893.)

234,103. LE DANTEC. A system of setting up electric batteries to effect complete depolarisation. (November 16, 1893.)

234,178. MILLAUD. Multiple-filament incandescent lamps. (November 20, 1893.)

234,191. LUC COURT & CIE. New dynamo brush-holder. (November 24, 1893.)

234,373. SOCIÉTÉ HILLAIRET-HUGUET. Apparatus for starting and stopping a dynamo at a distance by means of an electric detent. November, 30, 1893.

234,569. WOODRUFF. Improvements in electric incandescent lamps. (December 5, 1893.)

234,606. SOCIÉTÉ L'ACCUMULATEUR FULMEN. Improvements in electric accumulators. (December 6, 1893.)

CERTIFICATES OF ADDITION.

225,916. DION. Certificate of addition to patent taken out November 25, 1892, for an improved thermo-electric pile and process of manufacture. (October 5, 1893.)

230,889. DUJARDIN. Certificate of addition to patent taken out June 16, 1893, for improvements in electric accumulators. (November 25, 1893.)

COMPANIES' MEETINGS AND REPORTS.

Telephone Company of Egypt (Limited).

The eleventh ordinary annual general meeting of this Company was held on Tuesday, at the offices of the Company, 14, Austin Friars, Gen. Alexander Fraser, C.B., R.E., presiding.

The SECRETARY (Mr. Alexander B. Chalmers) read the notice convening the meeting and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN moved the adoption of the report and accounts, and said that the revenue account showed a credit of £4,192, which, with the £1,446 carried forward from 1892, brought up the balance for disposal to £5,638, out of which the Directors proposed to pay a dividend of 6 per cent. on the Preferred shares, tax free, to write off £69 for depreciation of stores, and to carry forward £1,948. He considered that for a small Company their affairs were advancing most satisfactorily. The management and control of the business in Egypt referred to in the previous year's report had involved an increased expenditure, which, with a considerable outlay incurred at Alexandria, Cairo, and Port Said, for re-construction, had been charged against the revenue of the year. The falling off in the net revenue, as compared with that of 1892, had been more than made good from profits from other sources.

Mr. HENRY GREWING seconded the motion, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. THOMAS LLOYD, the retiring Director, Mr. Grewing was re-elected.

The auditors, Messrs. Price, Waterhouse and Co., were also re-appointed, and the proceedings ended.

The following is the report of the Directors referred to above:—

After providing for debenture interest, the revenue account shows a credit of £4,192. 12s., and, including £1,446. 7s. brought forward from 1892, the balance for disposal is £5,638. 19s. The Directors propose to deal with this balance as follows:—To pay a dividend of 6 per cent. on the Preferred shares, free of income tax, to write off £69. 8s. 3d. for depreciation of stores, and to carry forward £1,948. 4s. 9d.

The arrangements in connection with the management and control of the business in Egypt referred to in last year's report have necessarily involved an increase in the expenses, which, with a considerable outlay incurred at Alexandria, Cairo, and Port Said for re-construction, has been charged against the revenue of the year. The net profit from the ordinary business of the Company for 1893 shows, therefore, a falling-off as compared with 1892, but this has been more than made good from profits realised from other sources. The business continues to develop, and the increase in the number of exchange and private lines during the year has been fairly satisfactory; the full effect of such increase will, however, only become apparent on the presentation of the accounts for the current year. The gross revenue of the Company from exchange and private lines, &c., on January 1st last was £13,100, as against £12,225 on the corresponding date in the previous year.

Bournemouth and District Electric Supply Company (Limited).

The third annual general meeting of this Company was held on Friday, under the presidency of Mr. Leveson Scarth. The Chairman, in moving the adoption of the report, which showed a net balance of profit of £964 on the year's working, said that the business was progressing with reasonable rapidity, and had now reached the stage of being a dividend-earning concern, the Directors having decided to recommend the payment out of profits of two-thirds of a 5 per cent. dividend on Ordinary shares, the Brush Company paying the remaining one-third under their guarantee, which does not expire till June next. The telephone difficulties are, the Directors trust, nearly at an end, as the Telephone Company are now adopting the system of complete metallic circuits for their currents, a method which, supplementing the continued efforts of the Company, will obviate all future trouble. The Directors had devoted much attention to mains and cables, and were incurring considerable expense in accelerating the policy of laying down concentric cables throughout the system. The plant at the central station has been and is still fully adequate to the load, as stated in the report, but the Directors anticipate an increase of at least 30 per cent. in the output during the ensuing year, and this would necessitate additional engines and alternators. During the last two months Mr. A. J. Lawson, M.I.E.E., London, has been acting as consulting engineer, and the Directors had appointed as resident engineer Mr. H. M. Sayers, at present engineer to the Electric Lighting Company in Oporto. Mr. Sayers will take technical charge of the Company's system as from April 20th. Mr. Shepherd's connection with the Company, for which he has done much work since its formation, has now terminated.

The report was adopted, and the retiring Directors and auditors were re-elected.

Southampton Electric Light and Power Company (Limited).

The following is the Directors' report presented at the annual meeting of this Company, held at the offices, Southampton, on Wednesday:—

The anticipations of your directors of steady and continuous progress in the business of the company have been realised. The increased revenue for 1893 amounts to £553. 9s. 10d. over 1892, but a satisfactory feature is that the expenses are practically the same, thus making the whole of the increase net gain.

Statement of Revenue and Expenses.

	Lamps (8 c.p.), 31st Decr.	Units Sold.	Revenue. £ s. d.	Expenses. £ s. d.
1891 (part only) ...	— ...	5,469 ...	350 5 11 ...	535 2 1
1892	2,200 ...	35,537 ...	1,153 4 10 ...	1,152 0 4
1893	3,162 ...	53,848 ...	1,606 14 8 ...	1,121 4 8

This statement is doubly gratifying inasmuch as the Directors reduced the maximum price of the current to 8d. from January 1, 1893. With the view of placing the Company upon a dividend-paying footing, your Directors have resolved to relinquish the fees already debited in the two previous balance-sheets, namely £400, and to take no fees for the year 1893. After debiting interest on debentures and overdraft and depreciation, a net profit of £170. 1s. 11d. is shown. This sum, together with £400 re-credited for Directors' fees, reduces the loss brought forward of £754. 19s. 9d. to £184. 17s. 10d.

As the sales of current for January and February of this year have shown an increase of 50 per cent. over the corresponding period of the previous year, your Directors feel justified in expressing the opinion that they will be able to declare a dividend at their next annual meeting.

To enable the Directors to cope with the new applications, it is highly essential that more capital should be forthcoming, and in view of the favourable showing of the Company's working, the Directors hope for the support of the shareholders in bringing fresh capital into the business.

The Directors who retire from office are Mr. J. F. Obree and Mr. G. J. Tilling, who, being eligible, offer themselves for re-election. The auditor, Mr. C. Cox, also offers himself for re-election.

CITY NOTES.

ALTRINCHAM ELECTRIC SUPPLY (LIMITED).—The Directors of this Company have issued a prospectus inviting subscriptions for 25,000 Ordinary shares of £1 each, payable 2s. 6d. on application, 2s. 6d. on allotment, and the balance in instalments of 5s. The prospectus states that the Company is formed to undertake the private and public supply of electricity in Altrincham and district. Subject to approval of the Local Authorities and the Board of Trade to the transfer, the Company has undertaken to purchase (at a sum expected not to exceed £900) a Provisional Order which has been incorporated into an Act of Parliament. Messrs.

Digitized by Google

Kincaid, Waller, and Manville have verified an estimated necessary expenditure of £22,000 to provide for an installation capable of supplying current to 15,000 8-c.p. lamps, and, it is estimated that the capital of £25,000 will be sufficient to meet the present requirements of the Company, whose total share capital is £50,000, in £1 shares. The list of applications closes on Tuesday next.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—This Company's traffic returns for the week ended April 1st amounted to £844, as against £744 in the corresponding period of last year, being an increase of £100. The total receipts for the half-year amount to £12,035, as against £12,015 for the corresponding period of last year, an increase of £20.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of March are £4,200, as compared with £4,275 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—This Company's estimated traffic receipts for the month of March amounted to £1,800, as against £2,015 in the corresponding period of last year.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend of 2s. per share, free of income tax (being at the rate of 2 per cent. per annum), for the quarter ended March 31st, which will be payable on and after the 24th inst.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the month of March amounted to £57,677, as against £55,786 in the corresponding period of last year, an increase of £1,891.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—The list will be found elsewhere of the drawing of 371 Five per Cent. Australian Government Subsidy Debentures of £100 each in this Company, which will be paid off at par, on July 2nd next, by Messrs. Barclay, Bevan and Co., bankers, 54, Lombard-street, E.C., after which date interest on these debentures will cease.——The accounts of the Company to December 31st last shows, subject to audit, a balance of profit of £189,080. 10s. 11d., after the payment of three interim dividends. The Directors propose to distribute, on the 19th inst., the usual dividend of 2s. 6d. per share, making a total dividend of 5 per cent. for the year 1893, together with a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year. The share register will be closed from April 11th to 13th inclusive.——The traffic receipts of this Company for the month of March amounted to £38,923, as against £46,204 for the corresponding period of 1893.

EDISON GOWER-BELL TELEPHONE COMPANY (LIMITED).—A brief notice of the meeting of this Company appeared in our last issue. Sir Alexander Armstrong, who presided, moved the adoption of the report and accounts. The Directors did not anticipate any return of capital on the 1,000 Ordinary shares in the Telephone Company of Austria, that concern having been placed in liquidation. An early decision was expected in the action against infringers of the patent in Belgium, the case being now before the Court of Appeal at Liége. With regard to the sum of £393,611 appearing in the accounts as expenditure on patent rights, concessions and exchanges, those relating to the Portuguese properties were represented by 37,400 fully-paid shares of £1 each in the Anglo-Portuguese Telephone Company, while similar rights in Austria-Hungary were represented by the 1,000 fully-paid Ordinary shares of £5 each in the Austrian Company already alluded to. There were no Directors' fees, and the expenses of management had been kept down to £230. 14s. Dividends for two years, amounting to £2,000, had been paid on the 20,000 Preference shares issued to the Consolidated Telephone Construction Company, and the dividend received as dividend on Anglo-Portuguese shares, less income-tax, £1,823. 5s. The reserve stood at £2,293. The motion to adopt the report was agreed to.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for March, 1894, amounted to £22,000, and from January 1st to March 31, 1894, to £63,000. In the corresponding months of 1892 and 1893 the amounts were £62,800 and £63,200 respectively.

GLOBE TELEGRAPH AND TRUST COMPANY.—The Directors have declared an interim dividend of 3s. per share on the Preference shares, less tax, and 2s. 6d. on the Ordinary, from which the tax has already been deducted.

W. T. HENLEY'S TELEGRAPH WORKS COMPANY (LIMITED).—This Company announce that warrants have been posted to the shareholders for dividends at the rate of 7 per cent. per annum on the Preference shares (free of income tax) for the half-year ended December 31st last, and 5 per cent. per annum on the Ordinary shares (free of income tax) for the year ended same date.

INTERNATIONAL ELECTRIC STORAGE (LIMITED).—Elsewhere will be found an abridged prospectus of this Company, which is formed to purchase and work the British rights in the invention of Messrs. Theryc and Oblasser for electric accumulators. Subscriptions are invited for the issue of £150,000 out of a total capital of £200,000, in £5 shares, of which the vendors and patentees take 9,000. On the present issue £1 is payable on application, £2 on allotment, and the balance as required. The Company also acquires by contract (the prospectus states) the right for 18 months to purchase the patents which have been obtained or applied for, for the same invention, in the United States, several of the British Colonies, India, and many of the principal European States. The Directors think the battery supplies a long-felt want, and that, in addition to the profits likely to be derived from working the business in the United Kingdom, further considerable profits will be obtained by dealing with the foreign patents. Private experiments have been made with the battery by the Paris, Lyons, and Mediterranean Railway Company, whose engineers have nearly completed a locomotive to produce nominally 700 H.P., which, it is stated, will run at a constant speed of 67½ miles per hour on the level, and 50 miles on gradients. It is further stated that the result of the trials of the accumulators on the tramway lines at Liége has proved sufficiently satisfactory for the tramways company to have obtained permission to run a tramcar equipped with these accumulators over its system. The prospectus contains extracts from a report by Dr. J. A. Fleming, which is favourable, as is also the report of Mr. A. Schanschieff, extracts from which are also given. The Company takes over a licence giving the exclusive right to use the invention for the lighting of road vehicles, and the business now carried on at Euston-buildings, London, W.C., and at High-street, Camden Town, for the working of this licence. It is stated that negotiations are nearly completed with the London Road Car, and other passenger-carrying companies for lighting their vehicles by electricity. The price to be paid for the British patent, and the right to purchase the Foreign and Colonial patents referred to, is £40,000 in cash and 8,000 fully-paid shares. The only contracts in which the Company are directly concerned are set out in the prospectus, complete copies of which, and forms of application, can be obtained at the offices of the Company, 73-75, Gresham House, Old Broad-street, E.C., or from the brokers, auditors, bankers, or solicitors. The Chairman of Directors is Major S. Flood Page, the consulting electrical engineer Dr. J. A. Fleming, the engineer Mr. A. Schanschieff, and the secretary Mr. J. G. B. Elliot. M. Ch. Theryc joins the Board after allotment. The prospectus is accompanied by a circular from the Universal Electric Lighting Company (Limited), who are the vendors, in which it is stated that "the invention of Messrs. Theryc and Oblasser constitutes one of the greatest, if not the greatest, advance which has yet been made in the application of electricity to practical uses," and "for a given weight this Company's battery has at least double the capacity of any other practical electrical accumulator in the market." It is further stated that "the important question of the validity of the patent has had the most serious attention."

ISLE OF MAN TRAMWAYS AND ELECTRIC POWER COMPANY (LIMITED).—Applications are invited for £125,000, in £1 shares, of the above Company, 50,000 of which are Six per Cent. Preference shares, and the remaining 75,000 Ordinary shares; 5s. is payable on application, 10s. on allotment, and the balance on May 1st next. £50,000 Debentures in bonds of £20 will also be issued, payable 10 per cent. on application, and the remainder on allotment. These Debentures are redeemable at par on May 1, 1914, and bear interest at 5 per cent., and form a first charge on the property of the Company, conveyed in security to the trustees for the debenture holders, and duly registered. The Directorate includes Dr. E. Hopkinson, who is also consulting electrical engineer to the Company. Dr. Hopkinson joins the Board after the completion of the works now in construction by Messrs. Mather and Platt. The Company is formed for the purpose of purchasing and working under one management the following tramway undertakings:—The Isle of Man Tramways, the Tramway over the Douglas Bay Estate, an extension now in course of construction from Groudle Glen to Baldromma, and an extension of the lines from Baldromma to Laxey. The Douglas Bay Estate line is expected to be open for traffic at Whitsuntide; the line from Groudle Glen to Baldromma about July 1st. The whole of the tram lines and property are to be conveyed to this Company under the agreements entered into, with the exception of about three miles, will be held by the Company in perpetuity, the tramways so held consisting of about 14 miles. There is a further three miles which the Douglas Town Commissioners have power to acquire by purchase. The purchase is made by the Company, including the whole of the property of the Isle of Man Tramways (Limited), and a quantity of valuable land, the electric generating station at Douglas, &c. In 1893 the number of passengers carried by the Isle of Man Tramways which the Company acquired was 911,410, an increase of about 100,000 over 1892, and the receipts show a profit of £3,784. It is estimated that the new lines and feeders will realise a total of £14,525, which, after paying interest on Debentures and Preference shares, will leave over £9,000 available for dividend, equal to about 12 per cent. on the £75,000 Ordinary shares. Additional revenue is expected from the sale of electric current in the neighbourhood of the Douglas generating station. The lists open on Monday next, and close on Saturday, the 14th inst., for town and country. Forms of application can be obtained from the Secretary, Mr. W. E. Young, Athol-street, Douglas; or of the Company's bankers and brokers. An abridged prospectus will be found on page xvi. of our present issue.

"JOINT-STOCK ELECTRICITY."—Under this title the *Financial Times* of Wednesday last contains a critical article dealing with the financial aspect of electrical industry and supply, from which it appears that the 14 supply companies operating in London and its suburbs have a paid-up share capital of £3,250,141, in addition to an issued loan capital of £604,600, making a total of nearly £4,000,000 embarked in the electrical supply business in the metropolis alone. The paid-up capital of 20 provincial companies amounts to £721,030, and the loan capital to £160,484. Nine of the principal manufacturing companies have a paid-up share capital of £2,051,654, and a loan issue of £365,130, or a gross total of £7,153,039.

MEDICAL BATTERY COMPANY (LIMITED).—A meeting of creditors in this concern has been held under the presidency of the Deputy Official Receiver, Mr. Warley, for the purpose of considering a draft scheme of reconstruction which has been put forward by the debenture shareholders, shareholders, and creditors of the Company. Apparently the last has not been heard of Mr. Harness and his so-called "electrical" dodges.

READING ELECTRIC SUPPLY COMPANY (LIMITED).—A prospectus is issued inviting applications in this Company for £45,000, in 9,000 shares of £5 each, payable 10s. on application, £2. 10s. on allotment, and the remainder at intervals. The list closes on Tuesday, the 17th inst. The Company is formed to work a Provisional Order for supplying the borough with electric current, which Order has been obtained in amity with the Reading Corporation, and has been duly confirmed by Act.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended March 30th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited) were £2,659.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the two weeks ending March 31st were £2,822, as compared with £3,357 for the corresponding period of last year.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 830.—Vol. XXXII. FRIDAY, APRIL 13, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The decision of the Court of Appeal has been given in favour of the London County Council in its dispute with the London Street Tramways Company as to the terms upon which that undertaking shall be purchased; in other words, the contention of the referee, Sir Frederick Bramwell, that he was precluded by the terms of the Tramways Act of 1877 from taking profits into consideration when assessing "the then value of the tramway," has been upheld. As we pointed out a week or so ago, this decision, although of some indirect interest to the electrical industry, does not immediately affect it, since the purchase clause of the Electric Lighting Act of 1888 is as explicit as that of the Tramways Act was vague.

The research of Prof. Ewing and Miss Helen Klaassen on the magnetic qualities of iron, which is appearing in our columns, being abstracted from the *Transactions* of the Royal Society, is the most important contribution to our knowledge of the actual material used by dynamo and transformer makers that has yet been published. Not only have practical samples been used, but they have been tested under practical conditions. Tests of iron without number have been made and published, but, either from nervousness or delicate feeling, the names of manufacturers and of users have been suppressed. Sometimes authors have feared to advertise a manufacturer, or to show up his poor work, and at other times tests have been made of iron which never has and never will be used by dynamo builders. Again, iron has been tortured through high inductions which give excellent lecture-room curves, but which give no useful information to transformer makers, and in other cases attention has been directed to the effect of extremely small magnetising forces. Some of these researches have formed valuable contributions to pure science, but every dynamo builder has not time to keep abreast with pure science, and, if such tests as those of Prof. Ewing and Miss Klaassen are not published, manufacturers must undertake them in their own testing rooms, and no one can complain if they decline to publish them.

Besides test of the samples, the effect of bending them to form rings for testing has been considered, and the effect of annealing on the various magnetic properties has been examined. One consideration seems to deserve more attention, namely, the frequency. To be thoroughly practical, without sacrificing a jot of science, the frequencies should be in the range of practical periodicities. The authors express "a doubt whether all that is possible has yet been done by manufacturers of iron to produce a quality specially suitable for such uses as the construction of transformer cores." The strangled discussion at the Institution of Electrical Engineers seven weeks ago was quite sufficient to show that this is more than doubtful.

Those of our readers who are desirous of obtaining information on the economy of steam pumps used for feeding boilers will do well to peruse a Paper on "The Working of Steam Pumps on the Russian South-Western Railways," by Mr. A. Borodin, published in the *Proceedings* of the Institute of Mechanical Engineers, No. 4, 1893. The author of this interesting Paper has made extensive trials of a large variety of steam pumps, some of which are well known within the walls of our electric supply stations. The quantity of steam consumed by these pumps, per effective horse-power hour, varied from 860lb. down to as low as 50lb., the former figure representing the economy of a pulsometer, and the latter that of a Worthington compound pump. From these figures it will be seen that the steam consumption by the feed pumps will generally be a by no means insignificant percentage of the total. Take, for example, a feed pump supplying a boiler with 2,000lb. of water per hour, under a pressure of 100lb. per square inch. The effective useful horse-power will be about 1·5 h.p.; and if we assume an average value for steam consumption, as given by Mr. Borodin, say 100lb. per horse-power per hour, there will be 150lb. of feed water per hour used solely for the pumping. This amounts to as much as 0·75 per cent.; and it is quite within the limits of practice for this consumption to rise to one or even two per cent.

The way out of the difficulty does not appear to lie in the design of more economical pumps; for, above all things, simplicity of working parts and ease of repair are the essentials in a power station feed-pumping plant. In many stations the heat of the exhaust steam from the pumps is utilised for heating the feed water; and by this practice there is no doubt that almost the whole of the exhaust heat can be restored to the boilers. This, in fact, is the very reason why the steam injector is such an efficient device, notwithstanding that it may require an enormous weight of steam per effective horse-power per hour. In the experiments recorded by Mr. Borodin an injector required no less than 1,440lb. of steam per effective

Digitized by Google

horse-power hour! Without doubt this is a very bad case, even for injectors; but if all the heat gets back to the boiler—who cares?

The recent recommendation of a Committee of the Worcester City Council, that the power developed at their new electric supply station should be utilised for pumping purposes at their water works (instead of steam as originally arranged), is one which shows that the Council has grasped the fact that work must be found for the supply station during the daytime. It has been decided to fix two sets of electric pumping plant, consisting of two 30-B.H.P. alternate-current motors having a guaranteed efficiency of 90 per cent., and two three-throw pumps capable of delivering 10,000 gallons per hour to an elevation of 300ft., through 5,000 yards of 10in. main. Electrical engineers will, we are sure, await with considerable interest the publication of the load factor and economy of the electric power station, after it has been working for a year or so under such favourable conditions. Whatever economy may ultimately be obtained, we are, at any rate, justified in saying that it ought to be a very high one; and we heartily commend to the notice of municipalities this very practical mode of giving steady work to their electric supply plant during the daytime.

Some further information on the new adiathermanous glass will be found in another column. Alum solution has long ago been shown to be little or no better than water as a heat screen, although alum crystals are good absorbers of radiant heat. It should be observed that while the first table relates to screens of one uniform thickness, so that the results are at once comparable, the second set in which the thicknesses differ cannot be directly compared, for the absorption is not proportional to the thickness. The effect of ferrous salts in solution is so remarkable that we hope further experiments will be made.

The general question of the screening of radiation is at present but little developed. In the present case it would seem to be due to resonance of the molecules either directly or by their action on the interstitial ether. A red-hot poker emits waves of all lengths down to about one forty-thousandth of an inch. Abney and Langley have made observations on waves of about one ten-thousandth of an inch, and between these and waves of half an inch there are some twelve octaves of completely unknown radiations. We cannot study them because we cannot generate them separately, though all are generated uselessly when light is produced. It is conceivable that some of these vibrations might be sifted out by means of suitable screens, and having been separated, they might be studied.

A man with a mission is commonly reputed to be a danger to the commonwealth; how much more dangerous, then, must be a Government Department with a mission, seeing that it is even more of an intangibility than a limited liability company. The Directors of the latter can occasionally be brought to book, and made to testify by their presence in the witness-box that a limited liability concern possesses a simulacrum of body and soul. But in dealing with a Government Department even this approximation to evidence of a bodily and spiritual existence is denied us, though the permanent officials are generally admitted to be its life and soul, and it has been averred, but never proven, that they have their departments under their thumb.

It is on account of this departmental elusiveness and the characteristic thoroughness with which the Board of Trade entered upon the mission, assigned to it by Parliament, of municipalising electric lighting, that we are glad to learn that the vagaries of one town council at any rate have received a check. For years past the corporation of a certain little town, not a hundred miles from London, has been "thinking of going in for electric lighting," and by judiciously-timed debates and reports has managed to do nothing itself, and at the same time keep everyone else from doing anything. Finally, the advent of a *bonâ fide* locally-supported company obliged the Corporation to state its readiness to give its consent, though only on condition that the promoters accepted a clause involving municipal purchase on an old-iron basis within 10 years. This was too much even for a department with a mission, and the Corporation was told that the Provisional Order Confirmation Bill would go forward notwithstanding its non-assent. Thus irreverently dealt with, the municipality now proposes to try and secure the reduction of the 42 years' period to 30 years. We wish it all ill-success in this venture: it is bad even for local authorities to be encouraged in the belief that they can eat the cake and have it.

An Alternate-Current Tramway.—The Creusot Works will exhibit an electric tramway on the alternate-current system at the Lyons' Exhibition.

The City Lighting.—The City of London Electric Lighting Company announce that they are now prepared to supply current in 406 streets, courts, lanes, &c., within the City, and that current will be laid on by the end of next month in most of the remaining streets.

Electric Traction in Switzerland.—The Bernese Oberland Railway Company is contemplating the substitution of electric traction for steam. The scheme is a very important one, comprising 200-H.P. locomotives, with 10 trains on the line simultaneously. Water power is plentiful.

Bristol University College.—Courses of lectures will shortly commence at this college, on civil, mining, and electrical engineering. The electrical engineering courses will comprise electric lighting, dynamo-electric machinery, and transmission of power.

Folkestone.—Last Friday, the Folkestone Corporation, after a sitting extending over four hours—the last of several meetings on the subject—approved of a scheme of electric lighting, at a cost of £35,000. There was considerable opposition, and several members of the Corporation who are shareholders in the Gas Company were not allowed to vote on the question.

Cable Interruptions:

	Date of Interruption.
Cayenne-Paramaribo	Oct. 15th, 1893.
Bissao-Bolama	Nov. 24th "
Garachico-Santa Cruz de Palma	Dec. 27th "
Fao-Bushire	Mar. 20th, 1894.
Bonny-Cameroons	Mar. 21st "
Brest-St. Pierre (P.Q. Co.)	Mar. 29th "

Rigidity.—This is the oracular manner in which a semi-scientific American contemporary announces the fact that no known substance is perfectly rigid:—"The form of no solid

matter or metal can be said to be fixed, under the possibilities of pressure equal to the flow of its atoms toward a readjustment of an equilibrium necessary to maintain a permanent form, by equalising or transferring pressures from a single direction to the multiple directions required for stability."

Death by Electric Current.—On March 16th last at Innsbruck a lamentable accident occurred. A high pressure circuit is carried on poles from the Mühlauerklamm to the town, and the telephone wire on the same poles being broken in several places by the weight of the snow, came into contact with the high-pressure circuit, and was hanging down to the ground. A young man named Würtemberger, passing the spot, went to clear the wire out of the way, and immediately fell dead. His companion and a neighbouring innkeeper, who tried to remove and restore him, thinking they saw signs of life, received severe shocks, but were not injured.

Electrical Bills in Parliament.—Amongst the Bills referred to Sir J. Kennaway's Committee, which will commence work on Thursday next, are the Charing Cross, Euston and Hampstead Railway Bill, and the London, Walthamstow and Epping Forest Railway Bill. It is stated that more petitions have been presented against the London, Walthamstow, and Epping Forest Railway Bill than against any other Bill before Parliament, with the exception of the Thames Conservancy Bill, against which 99 petitions have been presented. The Charing Cross and Hampstead Railway Bill is to confer further powers upon the Company, and enable them to acquire additional lands.

Electrolytic Sterilisation of Tetanus Filtrates.—The current number of the *Istituto d'Igiene sperimentale di Roma* contains an exhaustive and very important memoir "Sul veleno del Tetano," by Dr. Fermi and Dr. Pernossi. It covers close upon 60 pages, and records numerous experiments on the behaviour of the toxic soluble products of tetanus cultures under various conditions. Amongst these the action of heat was investigated, and it was ascertained that the tetanus-filtrate diluted with water was deprived of all pathogenic properties when exposed for one hour to 55° C., but when completely desiccated it was still toxic after being exposed for one hour to 120°C. The action of an electric current on its pathogenic properties was also examined, and they were found to be destroyed after exposure for about two hours to a current of about 0·5 amperes.

Lightning.—On Monday week during a thunderstorm at Thirsk, a large tree was struck by lightning. The tree was split, and the clothes of a youth sheltering under it at the time were burned off his back. The young man himself was seriously injured. On the following day a house situated in Oakes' Row, near Codnor Park, was struck by lightning.—The thunderstorm which occurred on Wednesday last was accompanied in the Luton district by a heavy downpour of rain and hailstones of an extraordinarily large size. The lightning near the town set fire to a barn and destroyed some outbuildings. About two miles from Harpenden the lightning killed three cows, and other damage is reported. During the storm, at Lampeter South Wales, a farmer's son was struck by lightning and killed instantly. The man was engaged in ploughing at the time.

Electrical Communication with Lighthouses and Lightships.—The Royal Commission on Electrical Communication with Lighthouses and Light-vessels have presented their second report, which recommends the establishment without delay of electrical communication by aerial wires between the telegraphic system of the country and a number of shore lighthouses and lighthouse stations. The Commissioners state that it is with regret that they have decided to confine their recommendations in this report to shore lighthouses; but until more has been done towards perfecting the communication of those light-vessels and lighthouses which were mentioned in the previous report as having the strongest claim to immediate attention, the Commissioners hesitate to add to the list of light-vessels and rock lighthouses with which they consider that electrical communication should be made. The report also recommends that the general lighthouse authorities should be invited to consider the general question of signalling with a view to institute a universal system of visual and sound signals at all the various light stations on the coast of Great Britain and Ireland.

Iron and Steel Institute.—The annual meeting of this Institute will be held, by kind permission, at the Institution of Civil Engineers, 25, Great George-street, on Wednesday and Thursday, May 2nd and 3rd, commencing each day at 10:30 o'clock a.m. On Wednesday, May 2nd, there will be a general meeting of members, the Council will present their report for the year 1893, and the President will deliver an address. On Thursday, May 3rd, the following Papers are expected to be read and discussed:—(1) "On the Physical Influence of Certain Elements upon Iron," by Prof. A. O. Arnold; (2) "On the Analysis of Steel," by H. K. Bamber, F.I.C.; (3) "On the Capacity and Form of Blast Furnaces," by William Hawdon; (4) "On Scandinavia as a Source of Iron Ore Supply," by Jeremiah Head, M.Inst.C.E.; (5) "On the Application of Electricity as a Motive Power in the Iron and Steel Industries," by D. Selby-Bigge; (6) "On the Walrand Process," by G. J. Snelus, F.R.S. (Vice-President); (7) "On Methods of Preparing Surfaces of Iron and Steel for Microscopic Examination," by J. E. Stead, F.I.C.; (8) "On the Relations between the Chemical Constitution and Ultimate Strength of Steel," by W. R. Webster.

Post Office Telegraphs.—The following figures from a Parliamentary paper ordered to be printed by the House of Commons last Session are of interest if only as showing exactly where we are in the matter of the telegraph deficit. The net telegraph revenue for the year ending March 31, 1893, amounted to £2,486,791. 5s. 1½d., and the "value of telegraph services performed for other public departments without remuneration" is stated to be £39,520. 18s. 1d. The total outgoings for the same period were £2,692,994. 11s. 2¼d., so that the year's operations resulted, if we consider the work done for public departments as having been paid for in hard cash, in a deficit of £166,682. 7s. 11¾d., which, if the interest on capital for the same period be added, is converted into a deficit of £465,570. 13s. The total deficit up to March 31, 1893, interest on capital being taken into consideration, was £4,929,257. 1s. 4d. On the other hand, if we only consider actual income and actual outgoings, this deficit is converted into an excess of receipts over expenditure of no less than £2,127,276. The capital expenditure on behalf of the telegraph service as shown by Government stock created now amounts to £10,868,663. 14s. 5d. In connection with this return it must be remembered, firstly, that extensions have almost entirely been paid for out of revenue, and secondly, that until the exact allocation of expenses as between the postal and telegraph departments is known, it is impossible to say whether the above big deficit is an actual fact or a mere matter of bookkeeping.

The Paris Bourse and Long-Distance Telephony.—The fussiness of officialdom, says the *Standard*, was amusingly illustrated and frustrated on the Paris Bourse last week. "It had hitherto been the practice for members who made use of the long-distance telephone there to run up a little account, which they settled before they went home for the night. The arrangement worked well; it must, therefore, be reformed. An order was issued that in future all messages must be prepaid, and that before entering the speaking chamber everybody was to state how many he intended to despatch. But neither in London nor in Paris is the stockbroker a person whom it is safe to trifle with. The complicated laws and customs of his own profession he obeys, and, in some cases, understands; but he is always ready to fight against rules and regulations imposed by outsiders—even her Majesty's judges. No sooner was the new edict promulgated on the Bourse than the members decided that it must be promptly withdrawn—like an Address in reply to a Queen's Speech or a General Strike Manifesto. With one consent they dispensed with the telephone, and the result of this boycotting was that the Post Office authorities, early in the afternoon, agreed to cancel the offensive order. The credit system being thus re-established, business was resumed, and the Central Administration began to earn their fees again. It is difficult to see what object was aimed at in the novel demand, since the amount of bad debts incurred under the old plan must have been infinitesimal. Nor is it quite obvious why the members

Digitized by Google

of the Bourse felt such a strong objection to the ready-money system, unless it be that men who habitually deal in large sums of money are generally reluctant to pay out small ones. A substantial cheque they will draw without wincing, but they do not like to part with their petty cash."

Small Arc Lamps.—A discussion on the potential possibilities of small arc lamps has been started in the *Electrical Engineer* of New York. Prof. Elihu Thomson writes that as far back as 1882 and 1883 he experimented with arcs using 2 to 3 amperes, and with a potential between the carbons of about 50 volts. An arc with 2½ to 3 amperes was readily obtained, and the mechanism for feeding, accurately, the carbon of small diameter was worked out, but the great difficulty at that time was that no carbons could be had pure enough or uniform enough in structure to permit such arcs to run steadily. Subsequently enclosing short-plate carbons in a chamber of glass with limited air supply or none at all was tried. This gave better results, but the carbons gave out enough impurities to obscure the glass in a moderate time. The actual waste of the carbon was very slow, and with a good arc length the light was quite steady. Very small arcs, says Prof. Thomson, when burned in the air with ordinary carbons, have a woeful tendency to rotation. Referring to the early difficulties of arc lighting, due to flickering caused by the use of inferior carbons, Prof. Thomson says, "There was, of course, an added prejudice against the light itself because it was a white light, or appeared bluish in relation to flames, torches, and such other 'hereditary' night lights. It is easy to account for such prejudice, and it is difficult to see how it could have been avoided. For countless ages the human race had relied for night light on fires, torches, lamps burning fats or oils—and the sensorium had come to expect a night light to be orange or yellowish in quality, and to be able to recognise no other to be in correspondence with hereditary expectation. Hence the sudden appearance of a white light at night was a sort of shock which could only be assimilated in the consciousness as something uncanny, inspiring dread or distaste rather than the reverse sentiment."

Electric Discharges.—At a recent meeting of the Académie des Sciences M. Lippmann presented a Paper by M. N. Piltchikoff, on a new method of studying the electric discharge. This method consists in joining one pole of a Voss electric machine to a metallic point which is held over a layer of castor oil contained in a copper dish, connected to the other pole of the machine. If the point is positively charged a large depression is formed, at the centre of which a secondary depression is seen if the distance between the point and the oil is diminished. If a small screen is placed between the point and the oil, an elevation is produced at the centre of the depression; the shape of this elevation being the same as that of the shadow that would be formed if the electrified point were luminous. The level inside this shadow is the same as that of the unaffected liquid, so that it appears that the screen stops the action and produced an electric shadow. The curious effect is shown in a very striking manner by the employment of mica screens cut into various geometrical forms; in every case the "shadow" formed on the depression was an exact reproduction of the screen. One cannot help being struck, says *Nature*, with the resemblance of the above experiment to some of those of Prof. Crookes. The same phenomena are produced with the negative discharge. The discharge acts in a very powerful manner, and the phenomena show themselves even when a strong blast of air is caused to play between the point and the oil. Using different gases the author finds that at the ordinary atmospheric pressure the electric shadows are in all cases the same; the only differences obtained were in the secondary depressions which appear when the electrified point is very near the surface of the oil. With very low pressures, however, the shadows are not formed. The author has succeeded in photographing the depressions and the shadows, and has obtained sharp and well-defined negatives with an exposure of about twenty seconds, showing that, at any rate for this length of time, the phenomenon does not change appreciably.

The Trans-African Telegraph Line.—From information furnished by the British South Africa Company, it appears that the telegraph company which Mr. Rhodes formed last year in London shipped to South Africa 400 miles of telegraphic plant, with iron poles and insulators of the same pattern as used for the wire connecting Cape Town with Fort Salisbury. Of this plant 200 miles were sent to Beira, and thence, *viâ* the Beira Railway and by ox-wagon, transported to Salisbury for the section of the line between that place and Tete, on the Zambesi, traversing the auriferous Mazoe district. The other 200 miles of plant was sent to the Chinde mouth of the Zambesi, and thence carried by steamers to Tschekwawa, a place about 140 miles up the Shiré river. Of this 200 miles 80 miles is being constructed backwards in a westerly direction to connect Tschekwawa with the Zambesi at Tete. The remaining 120 miles is to be erected northwards to Blantyre and Zomba, the British Consulate in the Shiré highlands of Lake Nyassa. Some months ago constructors were sent to Tschekwawa, and they have already constructed some 50 miles of the 80 miles connecting the Shiré with the Zambesi. Of this, 20 miles, completed and in working order, is in the Portuguese territory. The task of cutting the road from Tschekwawa to Tete has been an extremely difficult one owing to the denseness of the forests, but in three months of hard work the officials employed by Mr. H. H. Johnston, Her Majesty's Commissioner and Consul-General for British Central Africa, have made rapid progress. So thick is the growth of timber in this region, that the broad track cut for the telegraph poles resembles in many places a tunnel through the forest. The southern section of 220 miles between Salisbury and Tete is being erected under the superintendence of Mr. Gordon, a nephew of the late General Gordon. This section crosses the Zambesi to join the Shiré section at Tete, where, the river being broad, it was proposed to erect a lofty iron pole on an island in mid-stream. It was here that the recent collision with the Portuguese is said to have occurred.

Capt. Abney on Photometry.—At his second lecture at the Society of Arts, Capt. Abney dealt with the amyl acetate, Dibdin-Sugg-pentane, and Methven standards. Different chemical amyl compounds gave a light differing no more than 3 per cent. from that of the pure acetate, some being in excess and others deficient, the light even of impure amyl acetate was likely therefore to closely approximate to that of the pure substance. Photographic records were exhibited, showing that a slight difference in the actinic power of screened standards of the Methven type was caused by varying the height of the flame. Capt. Abney spoke highly of the Rumford or so-called shadow photometer which is not in favour among gas testers. The two disadvantages were, that with wide flames the junction of the shadows is ill-defined, in such a case a white band rather than an overlapping of the shadows is preferable; the other was that errors might arise if the screen were not perpendicular to the light; but, as Capt. Abney observed, a man must be a fool to allow such errors to occur. An inclination of 10deg. would give an error of 1½ per cent., and 5deg. only 0·4 per cent. Bunsen discs are likely to get out of order, and are therefore likely to lead to errors unless in the hands of an expert. The Methven standard is liable to error if used at short distances, since the thickness of the flame, as seen through the slot, must vary. A flat flame used behind a slot would give no such error. Capt. Abney went very fully into the question of scintillation produced by revolving sectors, and showed that the appreciation of a sensation of continuous or of scintillating light depended on the degree of illumination as well as on the frequency of extinctions. Similary, the appreciation of slight differences of illumination depend largely on the degree of the illumination. A strip of paper with a gradated series of tints from black to white showed each step clearly when brightly illuminated, but in a feeble light not only were the steps indistinguishable, but the gradation of the whole was much less marked. Text-books stated that the eye was able to detect certain small differences, and this value, whatever it was, was repeated, as errors are wont to be, in text-book after text-book. The fixed degree of accuracy of a photometer is quite illusory. With a feeble light, a difference of 2 per cent. or more is not appreciable, but with stronger lights, everything else being the same, one half per cent. or less can be detected.

REVIEWS.

Electric Waves: being Researches on the Propagation of Electric Action with Finite Velocity through Space. By Dr. HEINRICH HERTZ. Authorised English Translation: By D. E. JONES, B.Sc.; with a Preface by Lord KELVIN, P.R.S. (London: Macmillan and Co. 1893.)

The discovery of the Rosetta stone did not more completely solve the meaning of the hieroglyphic formulæ graven in the stones of Egypt, till then mere symbols devoid of physical significance, than have the researches of the late Dr. Hertz into the phenomena of the propagation of electromagnetic waves solved the physical meaning of the Maxwellian formulæ. Many had gazed at those algebraic signs in wonder at their true meaning; and, like Maxwell himself, had made isolated attempts with detached experiments to build upon them some physical basis. But it was not until the long line of careful research by Hertz had been well-nigh completed, that the inductive method of reasoning could safely be applied to their physical interpretation, and the medium of electromagnetic action could be defined. The observed inter-dependence of certain optical and magnetic phenomena had already given rise to a well-grounded theory of the mutual relationship between the two classes of physical action; but it was impossible to go much farther, or to say in what exact way the phenomena of light resembled the phenomena of electromagnetic action. Then Hertz struck the true key-note; and lo! electromagnetic waves were observed to have the same velocity as that of light, and to follow the same laws of refraction, reflection, and other modification of their paths. This was the grand solution; and onward from this point the studies of light and of electromagnetic waves proceeded in parallel, in regard to any attempt to investigate their inner nature or the nature of the medium of their propagation.

"To fully appreciate the work now offered to the English reading public," writes Lord Kelvin, in his most interesting Preface, "we must carry our minds back 200 years, to the time when Newton made known to the world the law of universal gravitation." Here, in the struggle between Newtonianism and the dying Cartesian doctrine, we have the battle-royal between the rival theories of action-at-a-distance and action-by-contact. The victory was to the former, for a time; and in the hands of Bernouilli, and subsequently of Boscovich, the doctrines of Newtonianism were carried far beyond the doctrines of the individual Newton. In fact, Newton expressed himself as being opposed to the notion of matter acting where it is not; though, as we see by his support of the emission theory of light, he was not prepared to accept the notion of a luminiferous ether. Newton, however, suggested, that gravitation might be explained as being due to a diminution of pressure in a fluid filling space. Thus the doctrine of an empty space, requiring the infinitely rapid propagation of a distance-action, held the field, and was recognised by scientists of the eighteenth century as the only plausible hypothesis. History repeats itself; and again the battle-royal was fought, this time, early in the nineteenth century, in favour of the ether hypothesis; and action-at-a-distance was mortally wounded. Before the phenomena of interference of light and the magnetic and electrostatic researches of Faraday, both the idea of empty space action and that of emission light propagation failed; and the propagation of force through the ether, and of light by vibratory conditions of the ether, came to be held as necessary doctrines. Later still, Maxwell assumed the existence of and investigated the state of stress in a medium through which electromagnetic action is propagated. The mathematical theory which he deduced gives a set of equations which are identical in form with the equations of motion of an infinite elastic solid; and, on this theory, the rate of propagation of a disturbance is equal to the ratio of the electromagnetic and electrostatic units. The experimental determination, by Maxwell and others, that this ratio is a number equal to the velocity of light in ether in centimetres per second, is a fact which gave immense strength to the Maxwellian hypothesis of identity of the light and electromagnetic media. But, although this is the case, the Maxwellian hypothesis, even when taken in conjunction with the experimental support which he educed for it, fell far short of being a complete demonstration of the identity of luminous and electromagnetic propagation.

It is a popular belief that the greatest scientific discoveries and inventions have been the result of pure accident. The belief is only supported by flimsy and superficial evidence. Nevertheless, it is worth noticing that Dr. Hertz was led to commence his series of researches into the propagation of electromagnetic action by what may, perhaps, be styled an accident. In other words, he was engaged upon quite a distinct line of research when certain unlooked-for phenomena attending the discharge of Leyden jars attracted his attention. Thus were initiated the researches which are recorded in the present volume; but it is safe to say that, in thus stumbling upon the problem, Hertz made the only stumble in connection with it. For there is not in the entire annals of scientific research a more completely logical and philosophical method recorded than that which has been rigidly adhered to by Hertz from start to finish. We can conceive of no more delightful intellectual treat than following up the charming orderliness of the records in the pages before us. Setting out with a definite purpose, Hertz took the measure of its length and breadth and gauged its relations to known facts; then proceeded, with infinite patience, to explore. Nothing could be more remotely removed from accident, stumbling or haphazard groping in the dark.

The progress of Dr. Hertz's researches was recorded from time to time in Papers contributed by him to *Wiedemann's Annalen* and other journals; and translations of these have appeared in the columns of *The Electrician*. The publishers of *Wiedemann's Annalen*, however, being unable to comply with the numerous applications made for copies of these researches, invited Dr. Hertz to prepare his Papers for publication in a collected form. It was felt to be best to reprint the Papers in the form in which they originally appeared, an explanatory introduction being written by their author, in which he describes the manner in which the investigations were undertaken, and discusses their bearing upon electrical theory and the criticisms to which they have been subjected. The collected researches were published early in 1892, under the title of "*Untersuchungen über die Ausbreitung der Elektrischen Kraft.*" The work before us is an admirable translation of the German original, by Prof. D. E. Jones, with a change in the title, suggested by Lord Kelvin, and with one or two slight alterations in the original notes. The researches themselves, as we have already said, are a splendid consummation of the efforts which have been made since the time of Maxwell to establish the doctrine of one ether for all energy and force propagation—light, heat, electricity, and magnetism. The original Papers, with their introduction, form a lasting monument of the work thus achieved. The able translation before us, in which we have a skilful blend of the original meaning with the English idiom, and which is copiously illustrated, places the record of these researches within the reach of the English reading public, and enables it to study this important and epoch-making landmark in the progress of physical science.

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(Continued from page 604.)

Relative Merits of Two-phase and Three-phase Currents.

Experts differ as to the relative merits of two and three phase currents. As regards the alternators and motors there is, perhaps, not much to choose between them. Machines designed for similar outputs, whether synchronous or non-synchronous, are found to have about the same efficiencies, starting torque, weight, and apparent watt consumption, the three-phase machines, however, being the better, according to

experiments made by Mr. Kolbein, the chief engineer of the Oerlikon Works. As regards the winding details, perhaps the two-phase type is the simpler. The main difference between the two systems lies in the relative weights of copper required in the conductors for given conditions, and the ease with which the currents may be handled, regulated and controlled.

The first experiments with three-phase working brought to light difficulties in the regulation of pressure between the three mains at the points of supply, when the currents in the three circuits were not approximately the same, which though since overcome to some extent, are greater than those obtaining with two-phase currents—they lie chiefly with the design of alternators and transformers. Two-phase currents, if worked

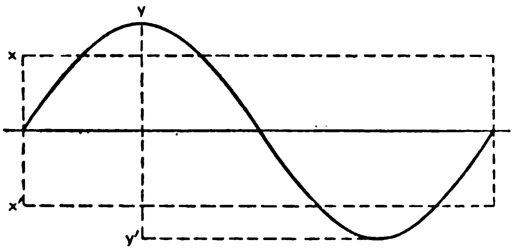

FIG. 96.—Single-Phase System.

xx' = Effective Pressure of 3,550 volts (*see* Table).

yy' = Maximum Pressure of 5,000 volts.

with *two separate circuits* are as easily dealt with as single-phase currents, and serve readily most purposes to which single or poly-phase currents are usually applied. They are specially convenient for distribution. It may be safely inferred that two-phase are better adapted for a combined service of light and power work; while three-phase currents are specially useful for running with equally loaded circuits, and therefore are not generally so suitable for lighting work.

For simple transmission of power between two distant points, however, the requirements are different, and the three-phase currents system is generally cheaper than either a continuous-current or a one- or two-phase alternate-current system.

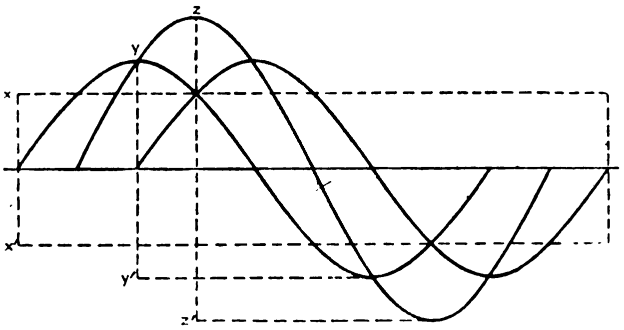

FIG. 97.—Two-Phase System. Three Wires.

xx' = Effective Working Pressure of 3,550 volts.

yy' = Maximum Working Pressure of 5,000 volts.

zz' = Maximum Component Pressure of 7,100 volts.

This interesting and important problem may be considered from three points of view, each of practical value :—

(1) On the basis of effective pressure at the distributing station (or motor terminals, perhaps).

(2) On the basis of maximum difference of pressure between conductors.

(3) When the economic law is considered.

The ratios of the weights of copper under these conditions are stated in tabulated form in the accompanying Table, in which, to give a practical character to the figures, a definite power has been selected for transmission to the receiving station. Constant line loss and constant fall of pressure have also been considered.

In the final column the economic law has been considered to the exclusion of either a definite line loss or drop, the equivalent current being taken as in column 3. In practice, the weights would be modified by local considerations; but the main ratios would hold good, and the figures given form, therefore, a reliable guide between the relative merits of the systems as affected by the weight of copper.

The significance of the difference between effective and maximum pressure is at once apparent if Figs. 96, 97, 98 and 99 are examined.

In these figures the *electrical centre of gravity* is shown graphically. In any electrical circuit of good or bad insulation there is a datum pressure with reference to the variations of pressure in the circuit. For example, in a continuous-current circuit the absolute pressure of the negative pole of the dynamo will have a constant ratio to that of the earth's surface at the particular site, and the difference of pressure

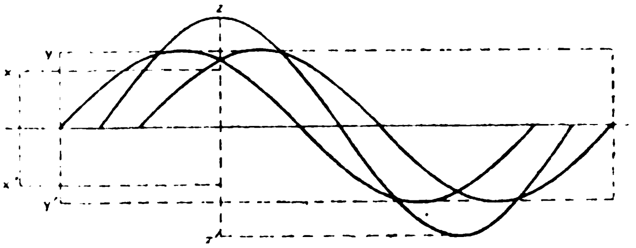

FIG. 98.—Two-Phase System. Three Wires.

xx' = Effective Working Pressure of 2,500 volts.

yy' = Effective Component Pressure of 3,550 volts.

zz' = Maximum Component Pressure of 5,000 volts.

between it and the positive pole will simply affect the absolute pressure of the positive pole. And if the negative pole be grounded, the datum pressure will be that of the earth's surface.

Again, with an alternate-current circuit, with both poles insulated, the cyclical changes will alternately raise and lower the absolute pressure above and below zero pressure, which corresponds to that of the earth's surface. Thus in a circuit carrying a current of 5,000 effective volts pressure the maximum pressure between any two points of the circuit will be $5{,}000\ \sqrt{2} = 7{,}050$ volts, while the absolute pressure, *i.e.*, *that* above the earth, will be only 3,525, positive or negative. The stress through the insulation to earth will, therefore, be only 3,525 volts.

But if the circuit be grounded, say, at one of the main terminals, the absolute pressure between the other terminal and

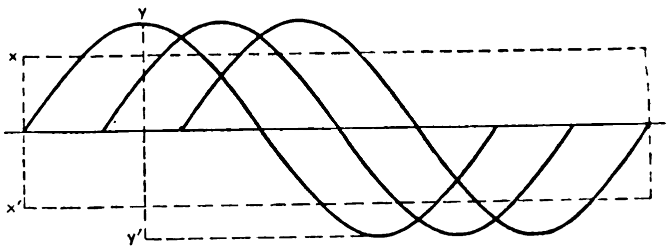

FIG. 99.—Three-Phase System.

xx' = Effective Pressure of 3,550 volts.

yy' = Maximum Pressure of 5,000 volts.

earth will be 7,050 volts, and therefore the insulation all over the high-pressure circuit will be subjected to this stress, although the effective working pressure will remain as before.

This possible change in the stress upon the insulation of a circuit carrying an alternate current has led to the general practice of earthing one of the primary mains, usually at both the generating and distributing circuits. The maximum stress is thus accepted and suitable precaution adopted to safeguard against accidents; and additional security is gained because a fault in the other main at any point at once blows the fuses and disconnects the faulty section.

With two-phase three-wire circuits it is permissible to earth the middle wire, at the generating station, which then is at zero pressure. The same precaution is observed with the "star" coupled three-phase system. With the "triangle" three-phase system it is not permissible to earth either of the mains, since the earth would then form part of the circuit.

	E.P. ditto ditto	5·78	5,000	5,500	8,700	1 × 500	86·5	0·435	0·866

* Effective pressure measured (*a*) with respect to the working pressure in each circuit, (*b*) with respect to the component pressure.

In the final column is given the necessary weights of copper, when the economic law is considered to the exclusion of either a definite line loss or drop, the equivalent current being taken as in column 3.

It appears, then, that from consideration affecting prime cost of line the three-phase system is cheaper for long-distance transmission than either single-phase or double-phase alternate currents. Continuous currents are the cheapest of all, but are not admissible for extra high pressures.

The selection of a system for a long distance transmission of power plant will mainly depend upon the maximum permissible pressure. If it be possible to work at such pressures as are feasible, in the engineer's judgment, for continuous-current dynamos (coupled in series or otherwise), then there can be no doubt from considerations affecting the line that this will be the cheapest and best system. But if extra high pressure be deemed advisable, then the three-phase system will generally prove the cheapest.*

In connection with this question it is important to notice that the engineers responsible for the electric transmission of power plant being laid down at Niagara, have finally, after mature consideration, decided upon a four-wire two-phase system. The reasons for their choice are given by Prof. G. Forbes, in a Paper entitled "The Electrical Transmission of Power from Niagara Falls," read before the Institution of Electrical Engineers on November 9, 1893. The details of the scheme have been strongly criticised by English experts, and the choice of two-phase currents is open to doubt. When it is considered that Buffalo, the nearest large city, is fifteen miles distant, it is clear that the weight of copper will be a very important item in the cost of the whole plant, and in the author's judgment a three-phase system would prove more economical in first cost, and give as good pressure regulation as the two-phase. For it must be recollected that there is a line difference of pressure of 20,000 volts, and hence step-down transformers will have to be used at every point from which power is taken. The *main line* drop will, therefore, be as difficult to regulate with two-phase as with three-phase currents; and variation of pressure of submains of the distributing systems can be as readily controlled by using *independent* secondary circuits from three-phase transformers as from *separate* secondary circuits of single or two-phase transformers, Prof. Forbes's argument that two-phase currents are more easily *redressed* than three-phase currents is probably sound, but the fact that no form of alternate current has yet been made unidirectional in a practical manner cannot be ignored.

* The generating plant may perhaps be a two-phase one, with suitable step-up transformers, as proposed by Mr. Scott, of the Westinghouse Company. And it may also prove economical to transform the phase again at the receiving station. The ingenious proposals of Mr. Scott, however, have not yet been verified in practice; but there seems to be no doubt of their feasibility and usefulness.

(To be continued.)

THE IMPORTANCE OF COMPLETE METALLIC CIRCUITS FOR ELECTRIC RAILWAYS.*

BY J. H. VAIL.

In the early days of electric railway construction two distinctly different systems were devised and competed for public favour. The one being the overhead double trolley system, affording a complete metallic circuit for the out-going and return of all the electric current required to move the motor cars, and the other being the single trolley system, using the track and earth as a common conductor for one side of the circuit, and the trolley wire and parallel mains for the opposite side.

The double trolley system was found impracticable of operation in many of its details, and the single trolley, because of its simplicity and convenience, has made rapid advances in public favour. The single trolley system has depended largely upon the earth and buried pipe systems for completing the circuit. Many devices for making the track and earth combined a more complete and low resistance circuit have been resorted to, such as burying copper or iron plates, old rails or old car wheels, and connecting same to the track; or, at frequent intervals, driving iron rod down in the earth and connecting by wires to track; or by making actual connection with wire from tracks to gas and water pipe systems.

* Abstract of a Paper read before the National Electric Light Association at Washington.

Digitized by Google

Also, for supposed reinforcement of the track, we have used a bare wire of iron or copper, buried in the earth, laid parallel to the track, and connected at frequent intervals; also the supposed electrical connection of rails at joints, by bond wires of iron or copper, only having a small fractional part of the capacity of the rail as a conductor. In the early days of electric railway construction it was assumed by experts that the earth and the buried pipe systems would, when combined, form an ample return for the electric current. At that age of the art experts did not fully appreciate the immense quantities of current that would require to be carried, and therefore did not foresee that these currents when disseminated would produce the serious results that have been caused by electrolytic action on systems of pipes buried in the earth and owned by other companies. Frequent tests prove that the earth itself cannot afford the free path for the current that was anticipated. Earth conductivity has been over-estimated. Iron and lead pipes, being better conductors than earth, must of necessity carry the current, if no superior path is offered by the method of construction. The natural moisture of the earth hastens the destructive electrolytic action of the current on these pipes In some soils electrolysis is more rapid than in others. The rapidity of action depends upon the chemical constituents of the soil. It has been found that illuminating gas leakage held in such soils as underlie the cities of New York, Brooklyn, Boston, Philadelphia and elsewhere, hasten electrolytic action. Abundance of substantial evidence can be produced. These serve to prove the case, which cannot longer be successfully denied nor assigned to other causes. It has been stated that in an electric railway system where a connection has been made to water pipes, the pipes have carried as much as 28 per cent. of the total current. Instances are known where as much as 40 per cent. is carried on the pipe systems. It is the opinion of the writer that any gas or water-pipe system used as a carrier of electric currents will not only be corroded through the body of the pipes, but will surely in due time show defects at joints, as here will occur higher resistance than in any other portions of the pipe system. It has been proven by test that the electrolytic action of even five amperes of current on an iron pipe is considerable, and that much damage will result in one year. The rapidity of action depends upon character of soil, amount of moisture, and quantity of current; the destructive action is constant and sure. Any system using ground plates, ground rods, or substitutes therefor, or bare return track wire buried in the earth, is constructed primarily to utilise the earth as return circuit; when the earth does not afford good return the current is sure to follow the water pipes, gas pipes, or other buried conductors offering the path of least resistance. We now see that these prove to have been only makeshift methods to reduce the cost of construction. We find that the evidence thus produced and the troubles constantly occuring in existing street railway systems are sufficient to show that all methods of grounding the track circuit or connecting to pipe systems should be entirely discontinued; it, therefore, becomes of vital importance to so construct the electrical railway system as to avoid all electrolytic action on buried systems of metal work that are the property of other concerns.

Having produced the evidence and established the case, let us briefly analyse the matter and ascertain the reason for these results. What was intended to be good has proved to be defective electrical work executed in connection with track systems, has not given to that side of the system a perfect path for the travel of the current; the conductivity of the rail circuit being impaired to such an extent that the electric current must force itself through the earth or through metal pipe lines buried therein.

A further examination into other features of construction requires some consideration of the bonding of rail joints. The existing methods of utilising railway tracks for conducting large quantities of current are faulty in at least three particulars—first, restricted conductivity at joint, due to insufficiency of the rail bonds; second, neglecting to properly utilise the track as a conducting medium; third, failure to provide a complete circuit of low resistance. For electrical purposes we cannot regard the joint plates and bolts as of any permanent value; the contact is electrically imperfect, the metal surfaces are oxydised and under constant movement, due to passing cars pounding the rail joints. The rail sections are in many systems of ample conductivity to carry more than the requisite current, provided they are perfectly bonded and properly connected by feeders with the dynamos. We must, therefore, bond the rail joint in such a *mechanical* manner as to maintain perfect *electrical* contact, and with sufficient metal to restore at the joint nearly the full conductivity as of the rail itself; and at the same time to give the existing joint plates their present freedom of motion.

It has been found that a system of track with faulty rail bonds will give a shock to animals and, possibly, to human beings, should the same be brought into actual contact in such a manner as to complete through them the broken circuit. It will be readily understood how difficult it is to maintain proper inspection of the electric bonding where the bonds are covered up by the street pavement. Under such conditions the ground circuit and the bonding escapes inspection until excessive coal consumption, loss of current, and other troubles, force themselves upon the attention of the street railway management. Observation proves that a faulty rail bond will show its location in winter by heating, due to high resistance, and if snow be present on the ground around the joints the snow is partially melted, thus indicating location of fault. Let us turn our attention for a few moments to the question of the conductivity of the rails.

According to statement of G. F. Sandt, which the author believes correct, the area in square inches of a single track of two 56lb. rails is 10·9748, and a single track of two 70lb. rails is 13·7186, while the safe carrying capacity, recorded at one-third that of copper in amperes, is respectively 780 and 976 amperes. The carrying capacity of copper wire between No. 10 B. and S. gauge and 1in. varies between 16 amperes and 302 amperes.

These figures serve to show how utterly absurd it is to bond a track of 70lb. T rails with iron rail bonds No. 4 or No. 0 in size, and to pretend to reinforce their conductivity with a No. 0 iron or even a No. 0 copper wire. It is laying a 12in. water main and then putting a ½in. pipe alongside to help it out. The No. 0 B.W.G copper wire has a resistance of over 20 times the single track of 56lb. T rails per foot, and the No. 0 B.W.G. iron wire over 112 times the resistance per foot of the same track. How, then, can either of these be of any adequate assistance for conducting current?

The writer knows personally of several instances where the copper supplementary wire has absolutely disappeared. The writer believes that 99 per cent. of the money expended for so-called supplementary wire is absolutely thrown away. The same money expended in other directions will give more adequate return. Does not this show conclusively that we should give our attention to the more perfect bonding of the rail joints, and also to apply track feeders in such a manner as to fully utilise the conductivity of the track, and thereby make it fulfil the service of which it is capable when properly treated? We are in error when the track system is named as a return circuit. The track system of all electric railways should really be the positive side or outgoing circuit.

It is also important that existing systems of operating electric railways should be promptly taken in hand and the proper remedies intelligently applied. The three-wire system has been mentioned by some engineers as a possible solution. I will here diverge for a minute to state that a trial was made four years ago under favourable conditions—not to avoid electrolysis, but to save copper. We developed physical difficulties of operation which warned us to avoid the three-wire system in future electric railway work. I believe I am safe in stating that 90 per cent. of the electric railways have their systems so constructed as to largely restrict the conductivity of the rail circuit. A one-sided system is fundamentally wrong. The quantity of current to be controlled is so enormous that ordinary make-shift methods will not answer. Having carefully analysed the whole matter, I feel justified in recommending that we must adopt the complete metallic circuit as the standard for the best electric railway practice. This can best be obtained by the following method—first, by so bonding the track as to render the rail joints of as low resistance and nearly equal conductivity to the rails, and to execute this work so as to maintain this improved condition; and, second, the track system must be supplied with insulated feeders leading direct from the bus bars in the station to predetermined points of the track system, and thus offer a perfect low resistance path for this side of the electric circuit, the some as is obtained with the trolley line and the overhead system. All of these features and improved methods have been put in practice by the writer.

The only proper system is one that affords a well insulated and complete metallic circuit of low resistance, that will give an ample path for the complete unrestricted circulation of the entire current from pole to pole of the dynamo, thus offering no inducement for the current to follow such conductors as gas or water pipes. I am not recommending extravagant methods, but only such as are deemed essential for economy, and of a practical nature for reducing expenses and augmenting dividends. The item of cost cannot properly be urged as an objection, because where the whole construction requires a large investment, every detail of the work should be so executed as to be permanent and enduring. If the details are carefully analysed it will be found that the cost of frequent reconstruction, maintenance and renewals of rail bonds and bare wire amount to an excessive rate of interest on original investment, and would soon pay the small additional cost to build a complete metallic circuit. The superior service obtained from a complete metallic system of low resistance with the proper application of insulated track feeders will, within a brief period, more than refund a reasonable interest on the investment through the saving of fuel alone, not counting other economies in renewals and maintenance. The tract feeder system will be far less costly than the double trolley system.

Digitized by Google

Whether track feeders should be laid underground or erected overhead is a question largely controlled by local conditions and capital available. I express a preference for underground work as being more permanent and subject to the least cost for repairs. The original construction is certainly more costly for underground. The actual cost of copper is the same in either. The necessity of constant repairs under existing methods, and the damage to water and gas pipes by electrolytic action, simply proves that it is but a question of time as to how long before electric railway companies will be forced to adopt the complete metallic circuit. Where experience and practical knowledge is applied the cost will not be excessive. It is not difficult to arrive at an exact method of doing the work, and an accurate estimate of its cost. The writer has observed on some roads that large quantities of copper for return circuits have been placed at great expense, apparently without a proper conception of how to obtain the best results. Frequently a far less amount of copper, judiciously applied for improved distribution by the feeder system, would give superior equalisation of pressure at reduced cost. If for the movement of cars singly or in quantities at a high speed the electric current is to be distributed uniformly over an electric railway system, the subject must be handled with as much scientific accuracy as is always used for a perfect system of incandescent lighting, in order to obtain equal distribution and free flow of current in both sides of the system.

The conductivity of the rails should be calculated with as much care as the overhead system, and when the track needs reinforcing the purpose should be accomplished by laying a thoroughly insulated main line (not a bare line) and making frequent sub-feeder connections bonded to the track. If used at all this main will be of large size. Such a system, accurately worked out, will show by actual test with instruments on the cars a surprising equality of electromotive force throughout a large territory.

A very careful test has been made with instruments on moving cars, throughout a system covering 40 miles of streets, with double tracks, equal to 80 miles single track. The readings showed—maximum volts, 512; minimum volts, 420. Average of electromotive force over entire system, 460 volts, the electro-motive force in station, at bus bars, being 520 volts. The feeders were calculated for 10 per cent. drop. The actual average drop from dynamo to motor does not exceed 12 per cent. This will be found to result in reduced fuel consumption, better working of the motors, a most satisfactory reduction in repair accounts, and an improved general economy of the entire system. In the system of distribution secured by the above method, the use of ground plates, rods or other insufficient methods is needless; the current travels only over the paths provided for it, and electrolysis of gas and water mains is entirely obviated.

ADIATHERMANOUS GLASS.

In our issue of January 19th, p. 288, we gave an account of some investigations by Herr Richard Zsigmondy on the absorption of heat rays by a new ferrous glass devised by him, and capable of passing light while acting as a screen to heat rays. That glass has now become known under the name of "Schirmglas," or screen glass. Herr Zsigmondy has been continuing his researches into the absorption of heat by different other substances, and Dingler's *Polytechnisches Journal* gives an account of these.

The following table shows the percentages of the heat of an Argand burner *transmitted* by layers of the following substances 0·38in. thick :—

Concentrated sulphuric acid	15·7
„ hydrochloric acid	14·0
„ solution nitrate of manganese	14·0
„ nitric acid	14·0
„ solution aluminium chloride	12·9
„ phosphoric acid	12·7
„ alum solution	12·15
Iron perchloride (2·8 per cent. iron)	11·2
Copper chloride (bright blue)	8·2
Ferrous ammonia sulphate, 4·7 per cent. iron, colourless	2·6
Solution of iron in orthophosphoric acid, 5·6 per cent. of iron, colourless	2·1
Green vitriol, acidulated solution, 8·9 per cent. of iron, almost colourless	1·19

The acids are thus better transmitters of heat rays than water (about 12 per cent.). The ferrous salts of iron are good absorbers of heat rays; and their efficiency does not depend on the chemical salt used, so long as the iron is present in the ferrous state, but on the percentage of iron in the solution.

As to glass, neither alumina, nor lead, nor zinc, nor baryta, nor boracic acid, nor an excess nor a deficiency of alkali, has any marked influence on its absorptive power for heat rays, so long as the glass is colourless; but when the glass is coloured the absorption for heat rays is sometimes greater. The following table gives the percentages absorbed by different samples chosen :—

——	Thickness in millimetres.	Percentage of heat transmitted.
Silver glass, bright yellow	1·1	64·5
Table glass, bright	2·8	63·2
Mirror glass	7·52	63·5
Chromium glass, bright green	3·43	61·3
Copper glass, bright red	1·8	61·1
Table glass, greenish	3·0	59·1
Bright opal glass (flame appears reddish through it)	2·0	57·7
Bright blue copper oxide glass	2·7	53·0
Yellow iron-manganese glass	1·7	53·5
Brown iron-manganese glass	2·6	42·7
Dark red copper glass	2·1	51·5
Blue cobalt glass	2·3	41·0
Dark blue copper oxide glass	2·5	34·0

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, April 13th.

PHYSICAL SOCIETY.

5 p.m. Discussion on: "Calculating Machines," by Prof. O. Henrici. After which the following Papers will be read: (1) "The Minimum Temperature of Visibility," by P. V. Gray. (2) "The Mechanism of Electrical Conduction," by C. V. Burton.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Ordinary Meeting at Westminster Palace Hotel. The following Paper will be read:—"Lubricants: their Use, Testing, and Analysis," by William F. E. Seymour.

ROYAL INSTITUTION.

9 p.m. Evening Discourse on: "Some Properties of the Electric Discharge through Gases," by Prof. J. J. Thomson, F.R.S.

MONDAY, April 16th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture. "Photometry," by Capt. W. de W. Abney, F.R.S.

TUESDAY, April 17th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "Electric Illumination," by Prof. J. A. Fleming, F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. The following Papers will be read: (1) "The Training of Rivers," by Leveson Vernon Harcourt, M.Inst.C.E. (2) "Estuaries," by Henri Léon Partiot.

WEDNESDAY, April 18th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. The following Paper will be read: "Design applied to Carpets," by Alexander Millar.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Meeting at 20, Hanover-square.

THURSDAY, April 19th.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. General meeting at 25, Great George-street. Presidential Address. The following Paper will be read:—"Description of the Grafton High-Speed Steam Engine," by Edward W. Anderson.

SOCIETY OF ARTS.

8 p.m. Foreign and Colonial Section. "Tasmania and the forthcoming Hobart International Exhibition, 1894-95," by G. Collins Levey.

FRIDAY, April 20th.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. General Meeting at 25, Great George-street. The following Paper will be read:—"Description of a Fluid Pressure Reversing Gear for Locomotive Engines," by David Joy.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting at 28, Victoria-street. A Paper will be read on "Secondary Batteries," by G. C. Allingham.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Early British Races," by J. G. Garson.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny

Editorial, Publishing, and Printing Offices :

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies :—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
- **VOL. I.**—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
- **VOL. II.**—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.
The same book in German, price 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 8s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRIC MOTIVE POWER. By A. T. SNELL. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

PRACTICAL MAGNETISM. By J. A. KINGDON. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

NOW READY.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK FOR 1894.

(THE BIG BLUE BOOK.)

1,000 pages of valuable information; 550 closely-printed pages of Directory matter.

Price 7/6, post free 8/3; abroad 8/10.

NOMENCLATURE AND SYMBOLS.

In spring, an electrician's fancy lightly turns to thoughts of nomenclature. Whether this be due to a brain overstrained by attendance at meetings of scientific societies during the winter, or to premonitions of a midsummer madness which culminates in a Paper on symbols or names for units, with perhaps a new unit or two thrown in, we cannot say. The scientific world has been invited at different times to adopt kilobarads, of which, eighty-nine go to a pound weight per square inch; micro-franks, one of which is equivalent to eighty ampere turns; thoms, millihens, "and twenty more such names . . . as these, which never were, nor no man ever saw." For the most part, this name-giving does not arise from the advent of new and nameless ideas, but is connected with those physical quantities which for no very obvious reasons have been called units. As soon as somebody recognises that a certain quantity is a unit, he yearns for a name wherewith to dub it. Mechanical engineers have observed, and have calculated, the effects of friction for years; but have never felt the want of a unit of friction, nor when they determine the friction of water in pipes by loss of head in feet are they blamed for suppressing certain dimensions. Engineers who do not know that M/LT^2 are the dimensions of stress, and who have no idea of what is meant by torque or radian, are quite familiar with the calculation of torsion or twisting moment in inch-pounds or foot-tons, and would not be grateful for a "unit" named after some celebrated millwright.

On June 17, 1890, the American Institute of Electrical Engineers proposed to connect the names of FRANKLIN and of HENRY with some electrical units. Amongst other electrical quantities which had acquired unit rank, but which had not received suitable titles, was self-induction; and as HENRY'S

Digitized by Google

claims to fame had been less widely recognised than those of FRANKLIN, the connection was pressed, and has now been adopted. On March 21st last, the same body urged that the honoured names of GILBERT, WEBER, OERSTED, and GAUSS should be associated with the "units" of magnetomotive force, magnetic flux, reluctance, and "flux-density." That GILBERT had no idea of magneto-motive force, and that OERSTED never imagined such a quantity as reluctance does not enter into the question at all. Our New York correspondent informed our readers in our last issue that "it is urged that there is a practical necessity for the adoption of names for magnetic units." And in its issue of March 31st, the *Electrical World* talks of "workers in practical electricity" having had "presented to them a system of practical magnetic units which seems as well if not better suited to their needs than any yet devised," as if something actually creative had taken place, and not merely a local christening. Do we want a unit of magnetomotive force? Does anybody outside the lecture-room use it? Is it not a clumsy analogical companion to the objectionable expression electromotive force? If something more practical than an ampere-turn is going to displace this well-known quantity, we shall be interested to see it. If 4π is going to be suppressed or included or dodged in some way, confusion is likely to arise. FARADAY gave us the idea of a line of force, and we have given it a quantitative value; the number of lines, define them how you will, is quite sufficient for all practical purposes without any new unit of magnetic flux, and *a fortiori* we can dispense with gausses. *Ars longa, vita brevis.* But to speak of gausses instead of "lines per square inch" will not greatly shorten art. Life, rather, will be more brief, for very worry of remembering what all these names mean. As far as reluctance is concerned, we are thankful to have the word, and this, with the symbol **R** to match the well-recognised **H** and **B** is quite sufficient, without any new name.

The question of symbols arises at once out of a discussion of names. The "Symbols for Physical Quantities and Abbreviations for Units," proposed by M. HOSPITALIER, and recommended by the Committee on Notation at the Chicago Congress have been issued by the *Electrical World* of New York, printed on a card for easy reference. These symbols were certainly not adopted by the Congress, and it is difficult to decide how much importance is to be attached to the recommendation of a committee. The table is useful for its columns of defining equations and for the dimensions of the quantities; but that is not its main object. It is doubtful whether a thoroughly representative international congress could, by discussion and amendments, produce a much better set of symbols, but for all that many writers will still decline to alter their custom and to adopt the characters selected by M. HOSPITALIER. The Frankfort Congress in 1891 gave some attention to this matter, and passed unanimously three resolutions of a general character. Physical quantities, such as current, were to be denoted by an italic letter a; units, such as the ampere, by a Roman capital A; and angles and physical constants, coefficients relating to properties of materials, such as μ for magnetic permeability, were to be denoted by Greek letters. This Congress went on, however, to "decide" that the practical electrical units should be represented by the capitals which constitute the initial letter of their respective names, A for ampere, F for farad, O for ohm, &c. Nearly three years have elapsed, but we are not aware that this decision has been regarded. M. HOSPITALIER's system was submitted to this Congress, and it was recommended that a committee should "kindly put the system to a practical test, and at the end of the present year (1891) publish the results of their examination in the technical journals." We are not aware that the Committee have kindly or unkindly done anything of the sort. M. HOSPITALIER asks us to use u for difference of potential and v for geometric volume, C for capacity, and K for moment of inertia. The thoroughly French I for the quantity which Frenchmen so curiously name *intensité du courant* is perhaps destined to supersede the C or the A used by some writers. The ragged German capitals for the chief magnetic units have given place in our columns and in the writings of most English electricians to block letters. The only argument that can be urged in favour of the untidy and indistinct German letters is that they were used by MAXWELL.

Having got his units and names for them, and symbols for the names, the electrician is not happy until he tacks prefixes on to them. The kilo-, milli-, centi-, are common, the deca- is rare, and the micro- is occasional. Messrs. HOUSTON and KENNELLY, however, are not satisfied with these, and in another column call attention to the claims of bicrohenrys, begafarads and quegohms. A writer hard-pressed for time or paper might, if he pleased, use such jargon in his note-book. He alone need understand it, and having invented it, may be expected to read it without much difficulty, but it is asking a good deal to invite the whole scientific world to bother itself with such prefixes. In the original report of the British Association Committee for the Selection and Nomenclature of Dynamical and Electrical Units, to which we owe the C.-G.-S. system, Mr. STONEY's suffixes, to denote the exponent of the power of 10, were recommended. Thus, the length of an earth quadrant is metre-seven, or 10^7 metres, and a horse-power is 7·46 erg-nines per second. The fact that this suffix system has not been generally adopted is sufficient reason for assuming that it was not wanted, sensible and easily remembered as it is.

OBITUARY.

PAUL JABLOCHKOFF.

An attempt to apportion a due share of credit for the invention of the steam-engine to Hero, the Marquis of Worcester, Savory, Newcomen, and Watt would be no more vain than to examine the proportion of honour which must be accorded to the inventors of the electric light. No one can deny a place to Paul Jablochkoff among the four or five men who by their scientific knowledge, their ingenuity, their perseverance, and by that art of convincing the public, which is so important an element of success—as success is generally measured—have given electric lighting to the world.

Paul Jablochkoff, who was born at Serdobsk (Government of Saratow) on September 14, 1847, died at St. Petersburg on Friday last.

M. Jablochkoff belonged to a distinguished and well-to-do family. His father was a municipal councillor and a member of the General Council of his province. His younger brother was, at the age of 28, a lieutenant-colonel in the Engineers, and took part in Skobeleff's expedition into Central Asia. M. Jablochkoff studied at the Military Engineering College at St. Petersburg, which he left in 1866. As he manifested scientific tastes he was sent to the Military Galvano-Technical School. His military service lasted five years, and in 1871, his particular aptitude for electricity having been noticed by his superiors, he was appointed director-general of the Moscow-Koursk telegraph lines for the Midi Railway Company. It was while he occupied this post and had the telegraph workshops at his disposal, that M. Jablochkoff began to take a deep interest in the subject of electric lighting. In the year 1872, the Nihilist propaganda first began to inspire terror, and when the Emperor travelled by rail it was decided to light up the track in front of the engine by means of an arc light. M.

Digitized by Google

Jablochkoff was responsible for the lighting on the Moscow-Koursk section, and the frequent failures of the apparatus then employed induced him, no doubt, to consider all possible means of improvement. In 1875 he quitted the Imperial Telegraph Service, and from that date devoted his time exclusively to scientific pursuits. Passing through Paris on his way to the Philadelphia Exhibition of 1876, M. Jablochkoff was so pleased with what he saw of that city that he never got any further on the road to Philadelphia. At this time there was being held in London an Exhibition of Scientific Apparatus, and M. Bréguet sent M. Jablochkoff to London to represent that well-known firm. On his return to Paris, the Bréguet workshops were placed at M. Jablochkoff's disposal. Eight months of experimental work resulted in the famous "Jablochkoff candle." This discovery gave an immense impetus to electric lighting. A company was formed to work the patent, and in May, 1878, a magnificent row of Jablochkoff candles lit up the Avenue de l'Opéra at Paris. The Jablochkoff system of lighting soon spread, and before long "electric candles" were burning at Rome, and on the Thames Embankment in London. The "electric candle," however, is by no means M. Jablochkoff's only claim to fame, as the following list of patents taken out by him will show:—The electric candle, the distribution of currents by means of induction coils, an incandescent Kaolin lamp, the distribution and division of the electric current by means of condensers, a voltaic battery consuming coal, an alternate-current dynamo, a sodium battery, auto-accumulators, and a ribbon-wound electro-magnet.

M. Jablochkoff's patent, No. 1,996, of 1877, for "Producing and Dividing Electric Light," was deemed, if we may judge by the peaceable manner in which royalties were paid to its owners, the now defunct Electrical Engineering Corporation, the master patent in this country for alternate-current distribution by aid of transformers, although both the drawings and the second claim show that the inventor had in view series distribution, and merely used the "induction-coils" as a convenient means of preventing the interruption of the circuit by the failure of any single lamp. When a petition for prolongation came before the Judicial Committee of the Privy Council in April, 1891, a most curious discovery was made in regard to this patent. It was found that whilst the blue paper covers bore the date May 2, 1877, the face of the specification was dated May 22nd, the consequence being that two communications "On a New Form of Electric Light," made to the Society of Telegraph Engineers on May 9th, by the Acting-Secretary, Mr. W. E. Langdon, and M. L. Denayrouze, of Paris, became instances of prior publication and invalidated the patent. Mr. Moulton, nevertheless, sought to secure a confirmation of the patent under the law of 1877, but to no purpose; the amended petition for confirmation and prolongation being dismissed on May 13, 1891. The importance of the invention with which Jablochkoff's name is chiefly associated lay in its simplicity. When M. Dumas, President of the Académie des Sciences, described the Jablochkoff candle before the Academy, he said: "This discovery involves the suppression of all the mechanism usually employed in ordinary electric lamps." The Serrin and Duboscq lamps, excellent in their way, could not be run in series; but the new candles could be so connected with ease. The English patent is dated, No. 494, February 6, 1877.

To-day Jablochkoff candles have almost disappeared, and arc lamps, with more or less complicated mechanism, are common. Jablochkoff, in fact, succeeded in "subdividing the electric light," that is to say, successfully ran a number of lamps in series. That his candles flickered more than mechanical arc lamps was but a small disadvantage compared with the so-called subdivision. Practical electric lighting may be said to date from the lighting of the Avenue de l'Opéra in May, 1878. In that same month Brush applied for his English patent, No. 2,003; and in October, five months later, began that extraordinary period of inventive activity which, to a large extent, must be considered due to Jablochkoff's success.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Continued from page 646.*)

Steam.

Steam and Water.—The working substance in the steam engine is either steam or a mixture of steam and water; and its behaviour, under whatever conditions of actual practice it may occur, is the most complex of all working substances used at the present time. Steam is either the vapour of water or a condition of gas produced by superheating that vapour. In this series the term *water* will only be applied to the substance in the liquid state, the term *steam* being applied both to the vapour and to the ultra-vaporous gas, which latter we shall find it convenient to call *gaseous steam.* Our knowledge of the relations between these three substances—water, steam, and gaseous steam—and of their individual relations to thermodynamic quantities, is derived from numerous sources, but principally from the careful and exhaustive series of researches undertaken by Regnault, and published by him in 1847.† Up to the present time this knowledge is very incomplete, and the formulæ expressing these relations are quite empirical. In other words, although we are acquainted with the manner in which the properties of the three substances vary, we are unable to deduce those variations, because we do not know enough about the molecular properties of the substances.

If a mass of cold water is placed in the bottom of a closed vessel fitted with a sliding top, as shown in Fig. 8, so that the whole of the enclosed space is filled with water; and if

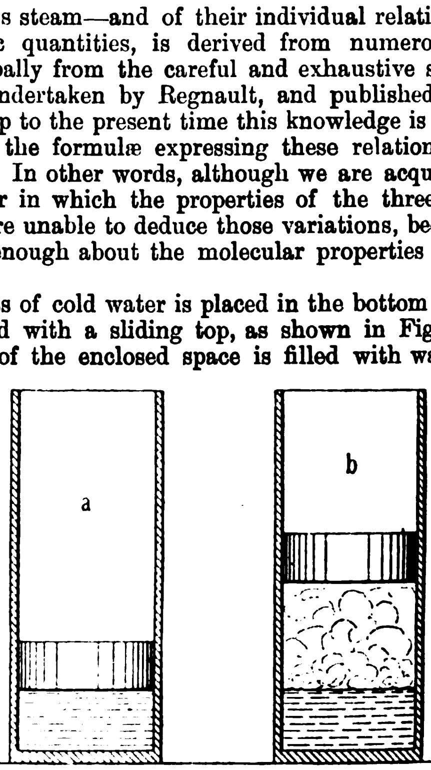

FIG. 8.

the water is now heated continuously, the following phenomena will be observed. We will suppose that it is possible to ascertain the temperature and pressure of the enclosed substance, as well as its volume, at any time. Let the external pressure on commencing be that of the atmosphere; and let the temperature of the water be that of melting ice (32°F.). At first, on the addition of heat, the volume will decrease at a slow rate and the temperature will rise, until 39·1°F. is reached. Then the volume and temperature will both increase as heat is added. Assuming the pressure on the piston to be unvarying, this will go on, and the enclosed space will be found to be always full of water, until a temperature of 212°F. is reached. Heat now added will cause the piston to rise at a much more rapid rate, and it will be seen that the increase of volume is due to the production of vapour between the piston and the surface of the the water. This transition is represented in Fig. 8 by *a* and *b*. It will be observed, however, that the addition of heat, no matter at what rate it may be added to the water, will not cause either an increase in the temperature or in the pressure of the steam, both these quantities remaining stationary till every particle of water has been passed into a state of vapour. The temperature at which this occurs is called the *boiling point of the liquid* or the *saturation point of the vapour*. Steam in this condition is called *saturated steam*. All the water having been evaporated,

Digitized by Google

it will be found that the addition of heat will cause a rapid rise in both the temperature and the volume of the steam; the rate of change in the relations between pressure, volume and temperature being much more rapid than in a perfect gas. The steam is now said to be *superheated*, and the rise of temperature above the saturation temperature is called the number of degrees of superheat. After a considerable number of degrees of superheat it will be found that the steam behaves according to Charles' law, the volume and absolute temperature varying in simple proportion. In this state, the steam is known as gaseous steam. Steam in which water is held in suspension is called *wet steam*; and saturated steam which is just on the point of rising in temperature on account of all the water having been evaporated is sometimes called *dry saturated steam*.

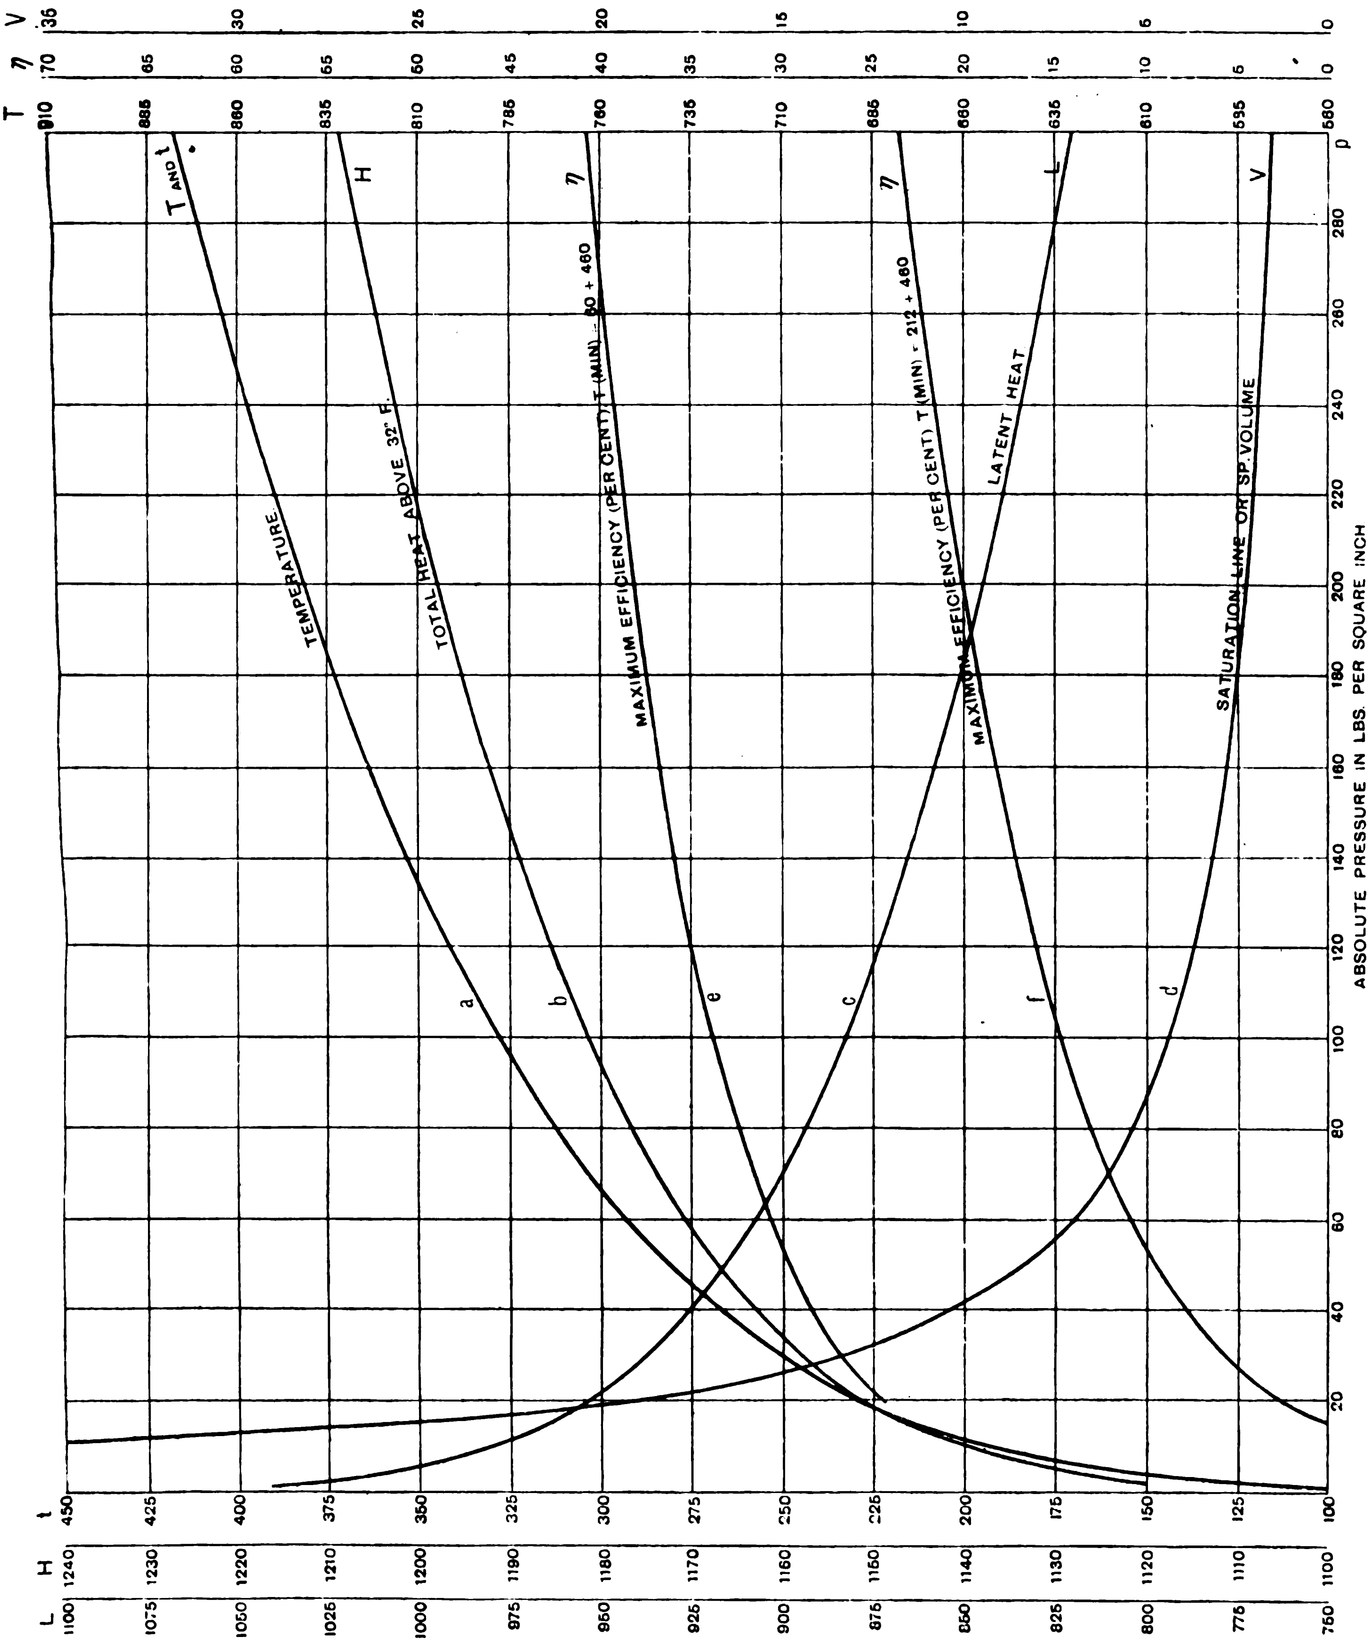

Fig. 9.

Thus far it has been assumed that the water and steam have been kept at constant pressure. Let it now be supposed that the foregoing experiments are repeated several times, during each time with a different pressure, either above or below that of the atmosphere. It will then be found that the general series of phenomena is always repeated, and in exactly the same order; but that the boiling point, or

saturation point, depends in every case upon the pressure; being a single-valved function of that pressure. In other words, for every pressure there is a definite temperature at which steam can exist in the state of saturation or at which there can be thermal equilibrium between steam and water with which it is in contact; this temperature varying with variations of pressure. If saturated steam apart from water, at constant pressure, is heated it will become superheated; if it is cooled it will partially condense; but the temperature and specific volume of the remaining vapour will remain unaltered. If saturated steam in contact with water has its pressure increased or decreased, it will rise or fall in temperature in such a manner that the temperature will always represent the saturation point corresponding to the pressure at the instant.

Properties of Saturated Steam.—As our knowledge of the properties of water and saturated steam is empirical, it will be most convenient to give at first the graphical representations of those properties, and to collect the empirical formulæ afterwards. A general study of these properties is perhaps best made by means of a set of curves such as will be found in Fig. 9. Here there are six independent vertical scales, each relating to the single horizontal scale of pressures. The six vertical scales are marked with index letters at the top and these letters are repeated at the extreme right end of the curves which relate to them. Thus, the curve (*a*) is marked T and *t* at the end, and gives on the scale T the absolute temperature, and on the scale *t* the ordinary temperature on the Fahrenheit scale, of the saturated steam. Similarly, the curve (*b*) gives on the scale H the total heat of 1lb. of the steam, reckoned above 32° F. The total heat is here considered to be the amount of heat required to raised 1lb. of water from water at 32° F. to saturated steam at the given pressure. It is equal to the sum of the latent heat of vaporisation and the sensible heat. The latent heat alone is given on the curve (*c*), as measured on the scale L. Both H and L represent heat in British thermal units per pound of steam. The relation between the pressure and specific volume of saturated steam is shown in curve (*d*), the specific volumes being measured on the scale of volumes, V, in cubic feet per pound of steam. This, the P.V.-curve of saturated steam, is often called the *saturation line.*

A close study of these four curves will reveal more than could be put into several pages of printing, so the author will avoid describing the most evident points of relationship between them, and will rely on the reader making a careful study of the curves. But a few important points must be briefly noticed. Firstly, it will be observed that the two curves (*a*) and (*b*) are sharply convex at the lower pressures, and tend to become almost flat and straight at the higher pressures, thus indicating that while the addition of a large amount of heat, or the production of a large increase of temperature, is necessary to give a definite rise of pressure when the pressure is very small, only a small rise of temperature, or a small increment of heat, will cause the same change of pressure when the pressure is initially high. For example, the difference between steam at 10lb. pressure and that at 20lb. is represented by the addition of 10·6 B.T.U. and a rise of 34·7°F. in temperature, while the difference between steam at 210lb. and that at 220lb. is represented by only 1·2 B.T.U. and 3·9°F. Secondly, of the total heat of the steam a lesser and lesser proportion is due to internal work and to the external work of increased volume, as the pressure rises. This is seen in the latent heat curve. Consequently, the curve of sensible heat—or the difference between the total and latent heats—must at all pressures rise at a greater rate than the curve of total heat.

Limiting Efficiency.—Since work can only be done in a heat engine by a fall in temperature of the working substance, saturated steam can only be made to do work by permitting it to fall in pressure. In a steam engine which works without expansion no working fall of pressure need occur; and in such an engine the work is done, not by the intrinsic energy of the cylinder steam, but by the latent heat of the evaporation of water at the surface of the water in the boiler. This will be evident when it is considered that the intrinsic energy of saturated steam is constant if the pressure is constant, which it is in a non-expansive engine. To perform work actually by the heat energy in a mass of saturated steam, that mass of steam must fall both in temperature and pressure; in other words, it must specifically expand. In ordinary engines the whole mass is made to expand, so that the total volume becomes greater; but it is conceivable that an engine might be constructed in which the specific volume of the steam might increase without any total increase of volume, a portion of the steam condensing to water. This would happen, for example, if the steam worked on a thermo-electric cycle. Now, the limiting or thermodynamic efficiency of the steam engine is determined by the temperatures between which the steam is worked, and therefore by the pressures between which the saturated steam expands, always assuming the steam to remain saturated. Moreover, since the lower temperature of the heat cycle may not be lower than that of the coldest of surrounding bodies—which is usually a supply of cold water—we may say that it is impossible to get a higher efficiency with saturated steam at any pressure than that which is fixed by the saturation point and (say) 60+460 absolute degrees. If we construct a curve which is the locus of these limiting efficiencies, we shall obtain the curve (*e*) in Fig. 9. It has not been thought necessary to plot this curve below 20lb. pressure.

Remembering that the efficiencies given by this curve on the scale, η, are the highest possible efficiencies where a natural temperature below 60°F. cannot be obtained, our first thought on looking at the curve must be that the steam engine is necessarily a very inefficient motor. And, indeed, this is the case, even to a more marked extent than is indicated on this curve. For, besides other sources of loss, it is practically impossible to work the steam down to so low a temperature of exhaust. One thing of importance, however, a cursory examination of the curve will reveal, namely, that it is possible to have a higher efficiency where the steam pressure is high than where it is low. This is the theoretical basis of the use of high pressures in steam working. The curve also shows that, whereas a small rise of pressure will produce a considerable increase in the efficiency where the pressures are low, even a very large rise of pressure will produce only a small increase of efficiency where the pressures are high. On this account, as we shall see more fully later, it does not pay to continue to increase the pressure of the steam beyond a certain point; for the prime cost and other expenses of the steam plant increase very rapidly with the pressure when the pressure is high.

Effect of the Atmosphere.—We have said that it is practically impossible to work a steam cycle down to a temperature of 60°F. There are several reasons for this, depending upon the special conditions in each case; but one of the most important reasons is the prejudicial effect of the atmospheric pressure. If the steam is exhausted from the engine into the air, or if some special means are not taken to prevent the atmospheric pressure being exerted against the moving parts of the engine, the lowest temperature down to which the cycle can be carried is that of steam at atmospheric pressure. For, if the air is allowed to exert its pressure on the exhausting steam, it will be useless to let the steam expand in the engine below the atmospheric pressure. For, if the expansion is carried beyond this point, then, although more energy may be taken from the working steam than would otherwise be the case, there will be a still greater amount of energy expended uselessly in overcoming the air pressure. The result would be a net loss of energy. Re-calculating the values of the limiting efficiencies for different pressures, on the assumption of a minimum temperature of 212+460 absolute degrees, we may plot the results and obtain the curve (*f*), which when read on the scale of efficiencies, η, is seen to be everywhere of lower value than the former curve. Two important facts are brought out by this curve: firstly, that a very considerable improvement of the thermodynamic efficiency of a steam-engine can be produced, at whatever pressure of steam it may be working, by screening the air pressure from the exhaust and working the steam down to the lower temperature which this practice

Digitized by Google

may permit; secondly, that the pressure at which the curve of efficiency tends to become flat is a higher pressure in the curve (f) than in the curve (e), or, in other words, that the practical improvement of the efficiency by raising the pressure may be pushed to a further point in the engine with air back-pressure.

(*To be continued.*)

ON CERTAIN NEW PREFIXES PROPOSED FOR PHYSICAL UNIT MAGNITUDES.

BY EDWIN J. HOUSTON AND A. E. KENNELLY.

The increasing extent to which scientific unit magnitudes are being used in physical research has received a check by the inconvenient size of some of the fundamental C.-G.-S. units. particularly the dyne and the erg.

In order to lessen this inconvenience we would propose the following additional prefixes, which we have found convenient in our own work.

For example, instead of writing one thousand megergs, we would suggest the term one begerg; and, similarly, for the expression one million megergs, the term tregerg, and for a billion megergs, a quegerg, following the analogy presented by the words million, billion, trillion, and quadrillion.

Again, instead of writing the one-thousandth of a microfarad, we would suggest the use of the term bicrofarad, and also the tricofarad as the millionth of a microfarad where necessary.

The meaning of these suggested prefixes is, therefore, as follows :—

Bega = 1,000 millions, or a billion, or 10^9.
Trega = one million million, or a trillion, or 10^{12}.
Quega = 1,000 trillions, or a quadrillion, or 10^{15}.
Bicro = 1,000 millionth, or 10^{-9}.
Tricro = one trillionth, or 10^{-12}.

The following applications of these prefixes will suggest their advantages :—

From 1 metre = 1·0 metre = 100cms.
and 1mm. = 0·001 metre = 0·1cm.
„ 1 micrometre = 1·0 micron = 0·000001metre = 10^{-6} metre = 10^{-4}cm.
„ 1 bicrometre = 1 bicron = 0·000000001 metre = 10^{-9} metre = 10^{-7}cm.
„ 1 tricrometre = 1 tricron = 0·000000000001 metre = 10^{-12} metre = 10^{-10}cm.

The micron is of the order of the length of a light wave in the ether, and is a fundamental unit of magnitude in microscopy.

The bicron is a magnitude which will be useful in dealing with the mean free path of gaseous molecules according to the kinetic theory of gases.

The tricron is of the order of atomic dimensions according to the estimate of Kelvin.

From 1 megadyne = 10^6 dynes = Approximately the earth's gravitational force on 1 kilogram of matter.
„ 1 begadyne = 10^9 dynes = Roughly the earth's force on 1 ton of matter, *i.e.*, the weight of 1 ton.
„ 1 tregadyne = 10^{12} dynes = Roughly the weight of 1,000 tons.
„ 1 megerg = 10^6 ergs = 0·0737 foot-pound at Greenwich.
„ 1 begerg = 10^9 ergs = 73·7 foot-pounds at Greenwich.
„ 1 tregerg = 10^{12} ergs = 73·730 foot-pounds at Greenwich. = 37 foot-tons approximately.
„ 1 megohm = 10^6 ohms
„ 1 begohm = 10^9 ohms = 1,000 megohms.
„ 1 tregohm = 10^{12} ohms = 1,000,000 megohms.
„ 1 quegohm = 10^{15} ohms = 1,000 tregohms.

A begohm is about the insulation of 1 mile of well-insulated conductor.

A tregohm is about the resistance required to limit the deflection of a high-grade mirror galvanometer under 1 volt to one scale division of 1 millimetre at 1 metre range. Such a galvanometer might be called a *tregohm galvanometer.*

A quegohm is the limiting resistance with 1 volt and unit deflection, of an extremely sensitive mirror galvanometer, which might be termed a *quegohm galvanometer.*

From 1 microfarad = 10^{-6} farad.
„ 1 bicrofarad = 10^{-9} farad or 1/1,000 microfarad.

The C.-G.-S. electromagnetic unit of capacity being 10^9 farads is consequently a begafarad. The use of these prefixes, therefore, assigns a convenient name to the C.-G.-S. unit of capacity, which would otherwise require a special denomination.

From 1 henry = 10^9 cms.
and 1 microhenry = 10^3 cms.
„ 1 bicrohenry = 1 cm.

WATER-TUBE BOILERS.

As a good deal of interest is being taken now in water-tube boilers, we take from the columns of the *Engineer* the following particulars of trials made at the works of Messrs John Barry Ostlere and Co., Limited, Kirkcaldy, N.B., on two Babcock and Wilcox water-tube boilers, one fired by a "Juckes" stoker, the other by a "Bennis" pneumatic stoker.

——	"Juckes" stoker.		"Bennis" stoker.		
Date of test	20/12/'93	21/12/'93	22/12/'93	25/12/'93	26/12/93
Length of test ......hours	9	9	9	9	9

The water was measured by means of tanks. Each tank contained 130 gallons, and there was an overflow equal to 282 gallons per 68 tanks.

THREE-WIRE DISTRIBUTION WITH A SINGLE DYNAMO.

The Compagnie de Fives-Lille, says M. Ch. Haubtmann in *L'Electricien*, have recently fitted six 60-H.P. dynamos with a device enabling each one of them to be worked separately on a three-wire circuit; one machine of the kind, coupled direct to a Willans engine, is to be shown at the forthcoming Exhibition at Lyons.

The Fives-Lille device is illustrated purely diagramatically in Fig. 1. The dynamo brushes, B_1 B_2, are connected to the outside leads, L_1 L_2, of the three-wire system, and two diametrically opposite points, a and b, of the armature are connected together through a low-resistance coil D, which possesses, however, considerable self-induction to prevent the short-circuiting of the armature. To the middle point, O, of this coil, the end of the neutral wire, N, is joined. In cases where it is not practicable to rotate the coil D with the armature two diametrically-opposite segments of the commutator are joined up to two collector

Digitized by Google

rings keyed to the dynamo shaft, and the ends $a\ b$ of the coil D take the form of collector bars, the neutral wire N being connected up as before to the middle point O.

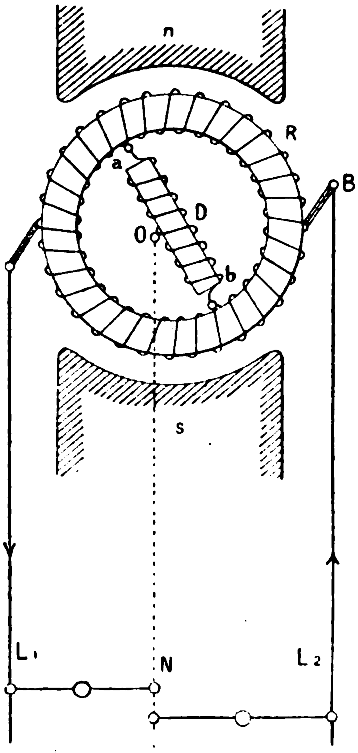

Fig. 1.

This device may also be used in the manner shown in Fig. 2, where the central station is supposed to be some distance from the area of supply, at the commencement of which one or

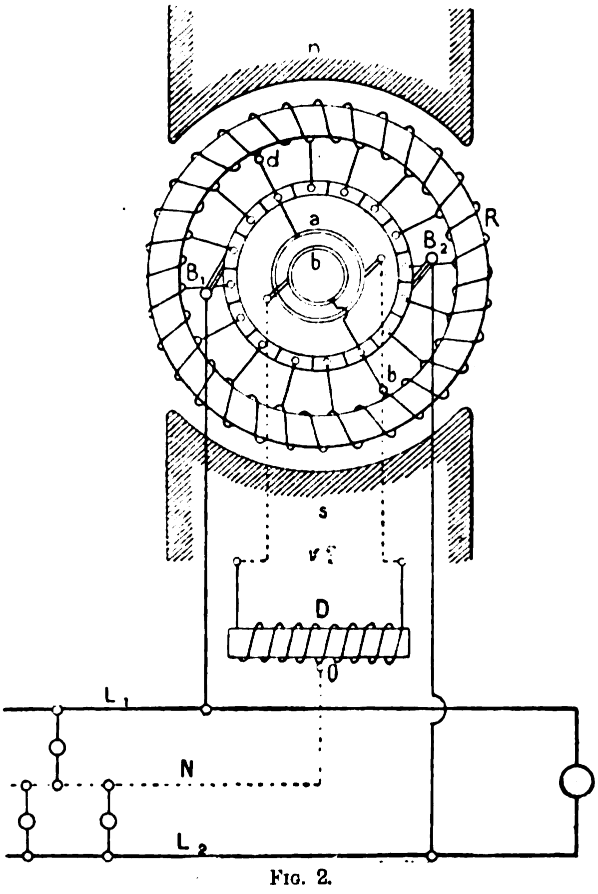

Fig. 2.

more of these "three-wire" equalisers may be joined up. It would seem as if the two sides of a three-wire system would have always to be very carefully balanced to prevent trouble with this device.

MAGNETIC QUALITIES OF IRON.*

BY J. A. EWING, F.R.S., AND MISS HELEN G. KLAASSEN.

(*Continued from page 640.*)

The next sample to be tested (Ring IV.) was of thin sheet iron, which, like the last, had been supplied to form the core of a dynamo armature. This iron, though supplied for a purpose in which magnetic softness is important, did not compare favourably with the thick sheet of Ring III. The ring was built up of 30 flat annuli, which were turned cut of larger punched discs. The thickness of the sheet varied in different discs from 0·044cm. to 0·050cm. The external diameter was 10·9cms. and the internal diameter 8·45cms., and the mean thickness of the sheets was 0·47mm. The discs were insulated from one another with paper. Nine cycles were

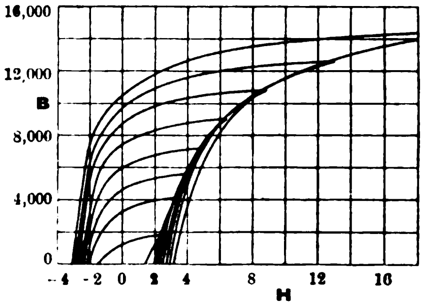

Fig. 11.—Ring IV. Thin Sheet Iron.

measured in the first instance, and then six small cycles, with a larger induction coil and a more sensitive adjustment of the current galvanometer. The results are given graphically in Figs. 11 and 12. The larger cycles, with the exception of the second, are drawn on Fig. 11. Fig. 12 exhibits the small cycles. The induction coil used in measuring the large cycles had 12 turns, but in the small cycles a coil with 195 turns was used to give a large magnification of the ballistic readings, the sensibility of the ballistic galvanometer itself being unchanged. The curves of the small cycles have been determined in this instance with particular minuteness, as a study of the behaviour of the iron under reversals of weak magnetising forces. In the lowest cycle the limits of the magnetising force are so narrow that the condition is approaching that of quasi-elastic magnetisation; there is, however, still a distinct trace of hysteresis.

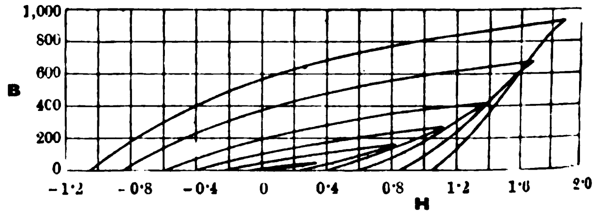

Fig. 12.—Ring IV. Thin Sheet Iron, Small Cycles.

From measurement of the curves of Figs. 11 and 12, the values of $\int H\, dI$ and of the coercive force have been determined, and the results are exhibited, with others, in Fig. 21. A reference to Fig. 12 will show that the overlapping of one cyclic curve by the next lower curve (corresponding to a slightly narrower magnetic range) is characteristic of low cycles as well as of high ones. The loss of energy in reversal (measured by the area enclosed within the curve) becomes very small, both absolutely and relatively to the magnetisation, in the lowest cyles; the molecular movements which constitute magnetisation are there approaching the almost perfect reversibility which, as Lord Rayleigh has shown, is attained when the range of force is still further reduced.

By way of further illustrating the behaviour of this sample under the weak magnetising forces of the small cycles, Fig. 13 has been drawn to show the total induced magnetism, and also the residual magnetism, in each small cycle, both in relation

to **H**. The figure forms an interesting example of the early stages of the magnetising process.

The next sample (Ring V.) was also of thin sheet iron. It was sent by Mr. Parker, of the Electric Construction Corporation, as a sample of the iron used in building up the cores of his transformers. This iron is supplied in sheets about 6ft. long and 3ft. wide, and its thickness is 0·367mm. To make the ring, a strip 2in. wide and 6ft. long was cut from the sheet,

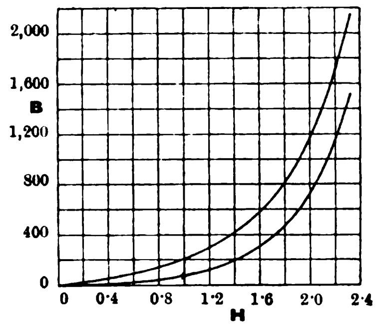

Fig. 13.—Ring IV. Thin Sheet Iron. Induced and Residual Magnetism under Weak Forces. Top Curve, Induced; Lower Curve, Residual Magnetism.

and this was coiled (along with a strip of paper for insulation) into a close spiral of the dimensions shown in the sketch (Fig. 14), the ends of the spiral overlapping one another for a centimetre or so. This is a convenient way of giving sheet metal the ring form suitable for ballistic tests; it is open, however, to the criticism that the bending of the metal is liable to harden it somewhat, especially near both surfaces, and it is possible that this consideration partly explains the comparatively sloping character of the curves (Figs. 15 and 15*a*)

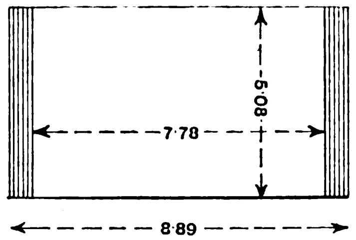

Fig. 14.—Section through Ring V.

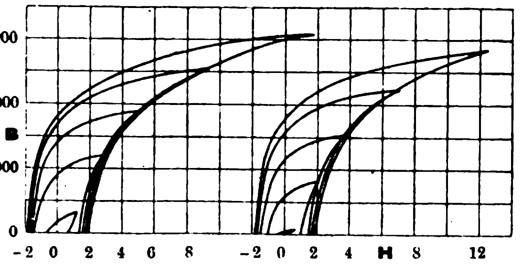
obtained with this ring. A similar remark, of course, applies in the case of rings formed by winding soft iron wire.

These cycles are shown in Figs. 15 and 15*a*. Measuring from the curves we have the results, which will also be found in Fig. 21.

The remaining specimens dealt with in this section of our experiments were of iron wire. In Ring No. VI. the core was of fine cotton-covered wire 0·34mm. in diameter, which was kindly supplied to us for the purpose of these experiments by



Figs. 15 and 15a.—Ring V. Soft Sheet Iron.

a leading firm of manufacturers at the instance of Mr. W. H. Preece. It was described as Swedish charcoal iron, but the tests show that it was decidedly hard in the magnetic sense, having a rather high coercive force and other characteristics resembling those of mild steel. Six cycles were measured, with results which are given graphically in Fig. 16.

The next specimen (Ring VII.) was also of cotton-covered iron wire, of larger diameter than the last, namely 0·975mm. It turned out to be only moderately soft in the magnetic sense. In addition to the measurements of magnetic cycles, the results of which are given below, and in Fig. 17 and 17*a*, several other experiments were made with this ring with the view of determining directly the heating effect of magnetic reversals. These will be described in a later part of this Paper. The ring had a mean diameter of 9·6cms., and the net area of section of the iron wire forming its core was 1·00 sq. cm.

For the last sample on our list (Ring VIII.) we are indebted to Mr. James Swinburne, who sent a hank of the soft iron wire used in the cores of his "hedgehog" transformers. The diameter of the wire was 0·602mm., and its surface was bright.

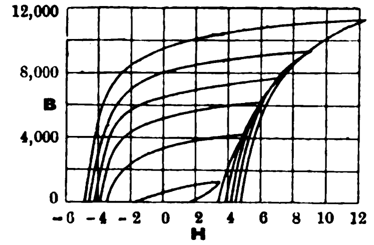


Fig. 16.—Ring VI. Fine Iron Wire.

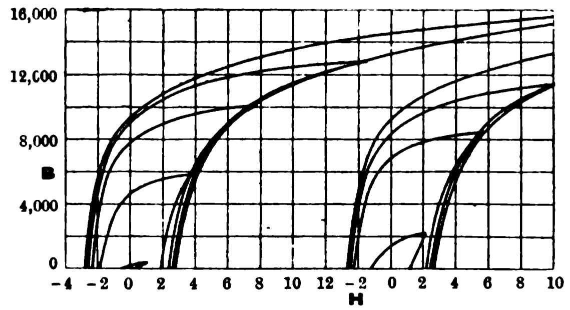
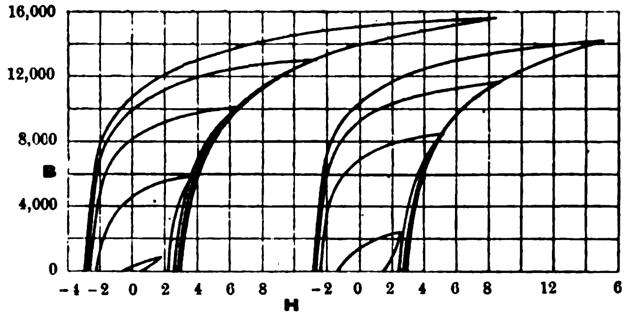
On winding it into a ring with a mean diameter of 2·75cms., without, in the first instance, taking any steps to secure insulation between neighbouring turns of the bright iron wire, we found that the Foucault currents in the ring were so influential as to make the ballistic tests of it in this condition worthless. In all the previous examples the wire or sheet metal forming the core had been insulated by cotton or paper.



Figs. 17 and 17a.—Ring VII. Iron Wire.

The ring was then soaked in a hot bath of boiled linseed oil, which was allowed to penetrate freely to the core—a treatment which, we believe, is similar to that actually followed in the building of the transformers. It appears that this was effective in preventing the Foucault currents from passing from wire to wire. Tests made with the ring in this state, which we shall distinguish as the first state, are shown in Figs. 18 and 18*a*.



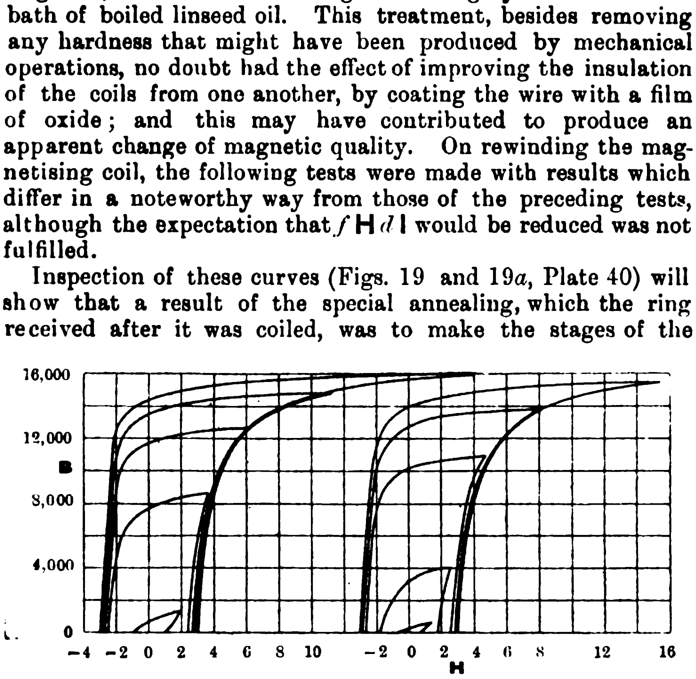
Figs. 18 and 18a.—Ring VIII., *before* Special Annealing.

The fact that the cyclic curves obtained from the metal in this state had somewhat rounded outlines, and gave values of $\int \mathbf{H}\, d\mathbf{l}$, which, though by no means exceptionally great, are greater than those given by the softest iron, led us to suspect that the metal had been slightly hardened, either in the manufacturer's hands, or in our coiling it into a ring for testing. Accordingly, we resolved to make another trial after annealing the wire in the coiled up state. The ring (No. VIII.) was

Digitized by Google

stripped of its magnetising coil, and was heated to redness in a forge-fire, after which it was again thoroughly soaked in a hot bath of boiled linseed oil. This treatment, besides removing any hardness that might have been produced by mechanical operations, no doubt had the effect of improving the insulation of the coils from one another, by coating the wire with a film of oxide; and this may have contributed to produce an apparent change of magnetic quality. On rewinding the magnetising coil, the following tests were made with results which differ in a noteworthy way from those of the preceding tests, although the expectation that $\int \mathrm{H}\, d\, \mathrm{I}$ would be reduced was not fulfilled.

Inspection of these curves (Figs. 19 and 19*a*, Plate 40) will show that a result of the special annealing, which the ring received after it was coiled, was to make the stages of the



FIGS. 19 and 19a.—Ring VIII., *after* Special Annealing.

cyclic process be much more sharply differentiated from one another than they were before. In other words, the curves are now exceedingly square-shouldered. The residual magnetism is high, and the rate of descent when reversal of magnetism is taking place is extremely rapid and uniform. $d\mathrm{B}/d\mathrm{H}$ in the higher cycles is about 13,000 at its maximum, and maintains a value little short of this, while B changes by as much as 20,000.

Fig. 20 has been drawn in further illustration of the magnetic qualities of this ring (Ring VIII. after special annealing). The curves in it show the whole induced magnetism and the residual magnetism (for each cycle) in relation to H. Taking the inclination of a tangent to the former curve drawn through the origin to measure the maximum permeability we find its value to be 2,420.

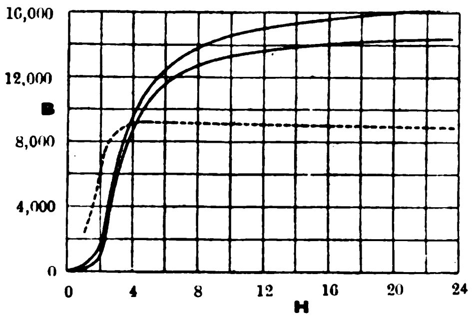


FIG. 20.—Ring VIII., *after* Special Annealing. Top Curve, Induced Magnetism; Second Curve, Residual Magnetism; Dotted Curve, Ratio of Residual to Induced Magnetism.

In the same diagram (Fig. 20) the curve drawn in broken line shows, in relation to H, the ratios of the residual to the induced value of B in each cycle. This curve rises with a rapid, nearly uniform, gradient (from a point to the right of the origin, since a finite amount of magnetising force may be applied without causing the iron to acquire any residual magnetism). It bends over fast when H is about 2·5, passes a maximum which is not sharply defined, and slowly falls as the magnetism is pushed into the region of saturation. Throughout the steep part of the magnetisation curve the difference between the residual and induced magnetisms scarcely increases at all, while B is increasing tenfold. The relation of the residual to the induced magnetism presents, in this and other respects, just those characteristics which the molecular theory (referred to below) would anticipate. In the present instance when the ratio is a maximum the residual induction is 93 per cent. of the induced.

The special annealing had hardly any influence on the value of $\int \mathrm{H}\, d\, \mathrm{I}$ and of the coercive force, notwithstanding its very considerable effect in changing the form of the cyclic curves, and in improving the permeability. The curve from Ring VIII. in Fig. 21 gives the relation of $\int \mathrm{H}\, d\, \mathrm{I}$ to B in this final state. The corresponding curve for the ring in its previous state would, if drawn, be nearly coincident with this one.

For the sake of comparison with these various specimens of iron we add here the values of $\int \mathrm{H}\, d\, \mathrm{I}$ (copied from *Phil. Trans.*, 1885, p. 556) obtained in tests made in Japan of a piece of soft iron wire. The method used in the Japanese tests differed from our present method; the specimen was a single straight piece, long enough to be practically endless, and its

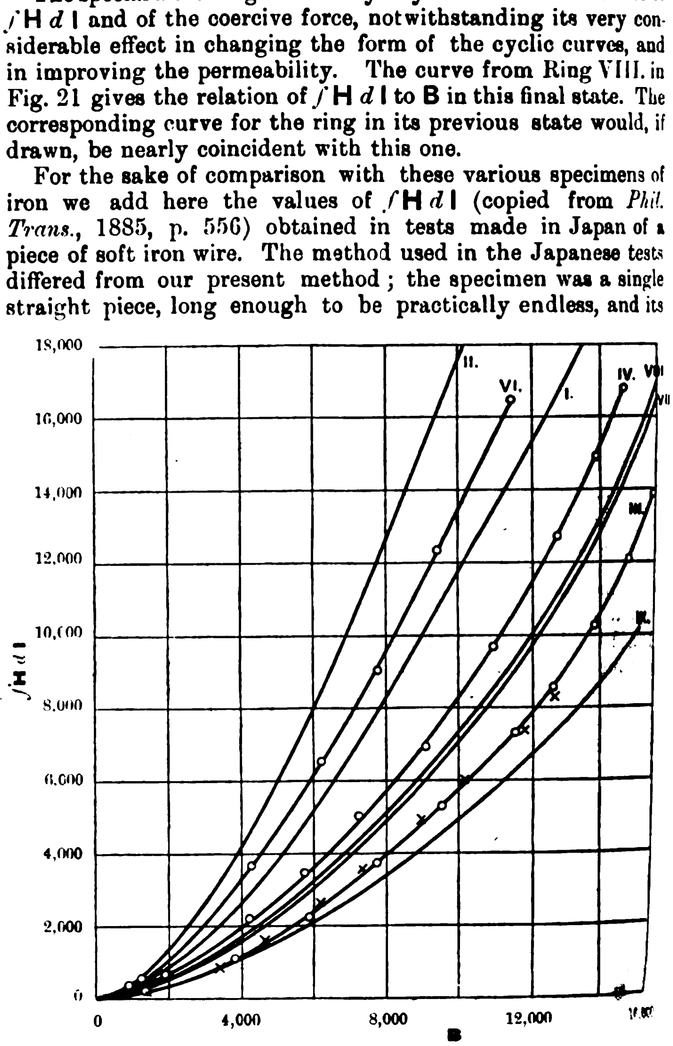

FIG. 21.—Curves of $\int \mathrm{H}\, d\, \mathrm{I}$ and B. Collected Results. The Crosses indicate Readings for Ring V.

magnetism was changed slowly, and was measured by a magnetometer. We have numbered these old tests IX. for convenience of reference.

IX.—*Old Tests made in Japan of a Soft Iron Wire.*

Limits of H.	Limits of B.	Limits of I.	$\int \mathrm{H}\, d\, \mathrm{I}$.
75·2	15560	1230	10040
26·5	13700	1090	8690
7·04	11960	951	6590
6·62	11480	913	6160
4·96	10590	842	5560
3·76	8790	699	3990
3·01	7180	571	2940
2·56	5950	473	2190
1·95	3830	304	1160
1·50	1970	157	410

None of the specimens tested at this time have given so low values of $\int \mathrm{H}\, d\, \mathrm{I}$ for the higher cycles, though the values in Rings III. and V. are practically identical with those in the Japanese iron for cycles in which B is less than 4000. The superior magnetic softness of this wire (No. IX.) was further shown by the fact that its coercive force after strong magnetisation was 1·75, whereas in all the rings now tested the coercive force exceeded 2. At least one other specimen of wire used in the Japanese experiments was as good.

The comparison suggests a doubt whether all that is possible has yet been done by manufacturers of iron to produce a quality specially suitable for such uses as the construction of transformer cores. The conditions of manufacture which secure

Digitized by Google

low hysteresis appear to be imperfectly known, or, at least, to be less generally recognised than electricians might wish. It must, however, be admitted that with respect to hysteresis losses under the comparatively low intensities of magnetisation usual in transformers, the sheet iron of Rings III. and V. is very nearly as good as the wire tested in Japan.

This will be apparent from Fig. 21, where the values of $\int H\,dI$ are plotted in relation to B for all the rings, and also for the wire in question (No. IX.). The figure shows in a striking way the extent to which the dissipation of energy in a cyclic magnetising process may vary in different specimens even of soft iron.

To facilitate comparison we also give a Table of Numerical Values of $\int H\,dI$, measured from these curves, for the various specimens of iron.

The values for Ring. V. are nearly the same as for Ring III.

- IX. Very soft iron wire (Japanese tests).
- III. Sheet iron, 1·95mm. thick.
- V. Thin sheet iron, 0·367mm. thick.
- VII. Iron wire, 0·975mm. diameter.
- VIII. Iron wire (of "Hedgehog" transformers), 0·602mm. diameter.
- IV. Thin sheet iron, 0·47mm. thick.
- I. Fine iron wire, 0·2475mm. diameter.
- VI. Fine wire, 0·34mm. diameter. Supplied as Swedish charcoal iron.

Again, Fig. 22 shows the relation of B to H for the various rings. The values of B are the limiting values in the successive cycles, and are measured, as we have already pointed out, after the corresponding magnetic force has been many times reversed. They are consequently rather lower, especially in the early parts of the curve, than those values of B which a first application of H would produce. Comparing the curves of Fig. 22 we see that high maximum permeability does not necessarily imply small hysteresis losses. Ring VIII. with its "square-shouldered" curve has a higher maximum of permeability than any of the other rings, though its hysteresis losses are much greater than those of Rings III. and V. And Rings III. and V. differ decidedly in permeability though their hysteresis losses are as nearly as possible equal. A reference back to Fig. 15 will show that the curves exhibiting magnetic cycles may assume a sloping form, implying comparatively little permeability, and yet enclose but small areas. When iron is spoken of as magnetically soft the implication sometimes is that its permeability is high, sometimes that its hysteresis losses are small. The two characteristics, are, however, in great measure independent. It is interesting to notice also that the easy slope of some of the soft iron curves in Fig. 22 allows them to be crossed by curves for steel, even under moderate magnetising forces. For instance, a force of 13 *c.g.s.* induces more magnetism in the rather hard steel of Ring II. than in the very soft iron of Ring V. A comparison of permeabilities in respect to any such force as this would furnish no criterion of magnetic softness. It may, however, be added that the specimens which are soft in the sense of having small hysteresis losses excel in permeability in the initial stage of the magnetising process. Compare, for instance, the relative permeabilities of the rings when B is say 1000: it will be seen that the order in which they stand in regard to smallness of hysteresis loss, and in regard to permeability, is at this stage the same. If softness is to be judged by the B-H curve it is clear that the early portion of the curve is the best guide.

Values of $\int H\,dI$.

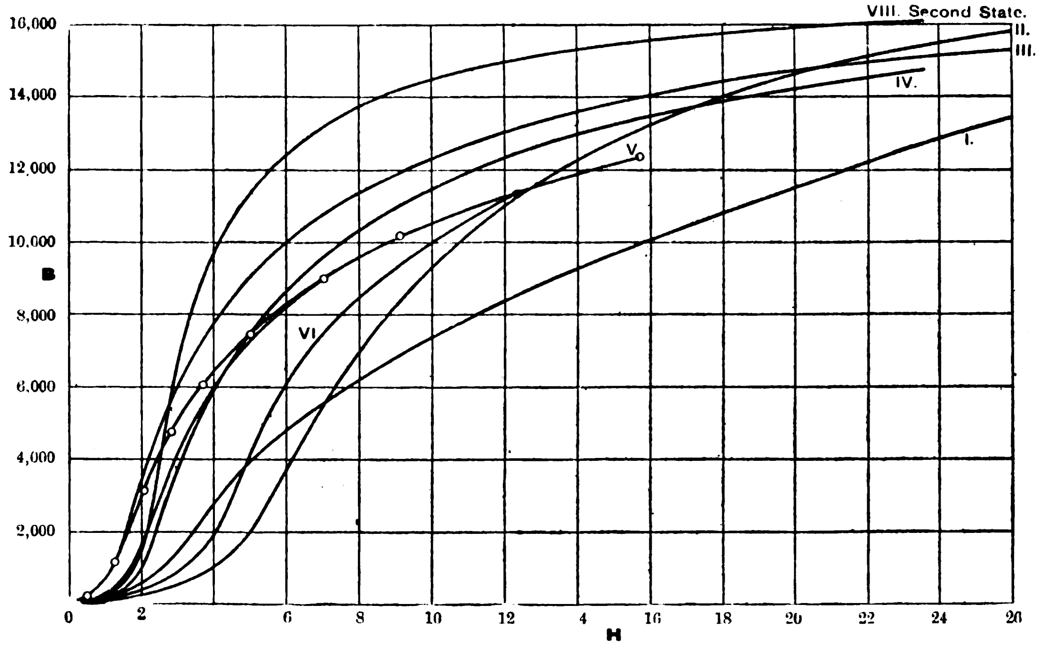

Fig. 22.—Curves of B and H

In a Paper read before the American Institute of Electrical Engineers* on the "Law of Hysteresis," Mr. C. P. Steinmetz has discussed certain experiments on the relation of $\int H\,dI$ to B, and contends that the empirical formula

$$\int H\,dI = \eta\,B^{1\cdot 6},$$

where η is a constant factor, is in good agreement with the results of experiment. From the figures Mr. Steinmetz gives, and from those which our own experiments supply, it appears that within a certain range of values of B this formula may be taken as giving a fairly close approximation to the real value of $\int H\,dI$. As an empirical formula of the kind is of use to designers of transformers, we have been at some pains to examine how nearly and within what range a formula of this type may be taken to represent the facts. It will suffice to refer to one example in some detail.

Taking Ring IV. (thin sheet iron) for which we have a

* *Transactions* of the Institute, January 19, 1892, vol. 9, p. 3.

Digitized by Google

numerous and very consistent series of determination of $\int H\,dl$, extending from $B = 43$ to $B = 14{,}720$, we have tested the constancy of the index ϵ in the formula

$$\int H\,dl = \eta B^{\epsilon}$$

by plotting log B in relation to log $\int H\,dl$.

From $B = 2{,}000$ to $B = 8{,}000$, the curve obtained in this way is a good straight line giving the value 1·475 for the index ϵ, and 0·01 for η. When B is about 8,000 the inclination of the line changes, and from $B = 8{,}000$ to $B = 14{,}000$ we again obtain very nearly a straight line giving $\epsilon = 1{\cdot}70$ and $\eta = 0{\cdot}00134$.

Again, the measurements obtained from the small-cycle tests of Ring IV., show that from $B = 200$ to $B = 500$ the curve of log B and log $\int H\,dl$ is very closely a straight line, giving $\epsilon = 1{\cdot}9$.

Where B is above 500 the gradient of the line gradually changes. Taking the region from $B = 500$ to $B = 1000$ the value of ϵ is 1·68, while from $B = 1000$ to $B = 2000$ it is 1·55.

From these results it is clear that no formula of the type under consideration, with a constant index ϵ, will serve to represent the results within anything like the limits of experimental accuracy. The index begins by being 2 or nearly 2 (a result which follows also from Lord Rayleigh's experiments*): in the ring referred to, this decreases to about 1·47 in the region of high permeability, and then increases again to 1·7 when the "wendepunct" is passed. The changes in the index, indeed, correspond to the passage from one to another of the familiar successive stages in the process of magnetisation: comparatively high values of the index are found first in the initial stage of low permeability, and again in the stage of strong magnetisation when the permeability is reduced by the approach towards saturation, while in the intermediate stage where the curve of B and H is steep the index is decidedly low. The well-marked changes of gradient curve which characterise the magnetising are accompanied by scarcely less well-defined changes on the part of the index ϵ and the factor η, in the empirical formula devised by Mr. Steinmetz.

While, therefore, a formula of this type cannot be admitted to have any physical significance, it may still be serviceable in giving rough approximations for the purposes of the electrical engineer. Though the formula is by no means to be accepted as an equation to the actual curve of $\int H\,dl$ and B, the curve which it gives by a suitable choice of index ϵ and factor η lies fairly close to the actual curve, intersecting it at an intermediate point as well as at two extremes. And it is the case that an index of 1·6, or a number approximating to that, gives a curve lying generally in the neighbourhood of the true curve throughout the range of B which is of most practical importance. In the case of our Ring IV., for instance, the formula

$$\int H\,dl = 0{\cdot}0034\,B^{1{\cdot}6}$$

give values of $\int H\,dl$ which are nowhere (within the range of these experiments) so grossly divergent from the truth as to unfit them for use in calculations connected with transformer design. Thus we have:—

B.	Actual value of $\int H\,dl$.	Value calculated from the above formula.
150	7	10·3
300	31	31
500	80	71
1,000	256	215
2,000	750	650
4,000	2,030	1,970
6,000	3,700	3,780
8,000	5,820	5,930
10,000	8,340	8,540
12,000	11,550	11,430
14,000	15,200	14,630

The divergence is becoming considerable at the top of the range, but elsewhere the agreement is fair. It should, however, be observed that if we wish to make the curve given by the empirical formula coincide with the real curve throughout any short part of its range, other, and often very different values must be given to ϵ and η. Thus, if the part from $B = 2{,}000$ to $B = 8{,}000$ only is considered—a part which includes those values of B which are usual in transformer cores—the formula

$$\int H\,dl = 0{\cdot}01\,B^{1{\cdot}475}$$

will express the results very much more closely. For example:—

B.	Actual value of $\int H\,dl$.	Value calculated from the expression 0·01 $B^{1{\cdot}475}$.
2,000	750	740
3,000	1,350	1,345
4,000	2,030	2,060
5,000	2,820	2,860
6,000	3,700	3,740
7,000	4,650	4,690
8,000	5,800	5,720

Throughout this not inconsiderable range of magnetisation (the region, namely, of high permeability) the agreement is good, but other empirical constants are required to fit the earlier, and again the later parts of the curve.

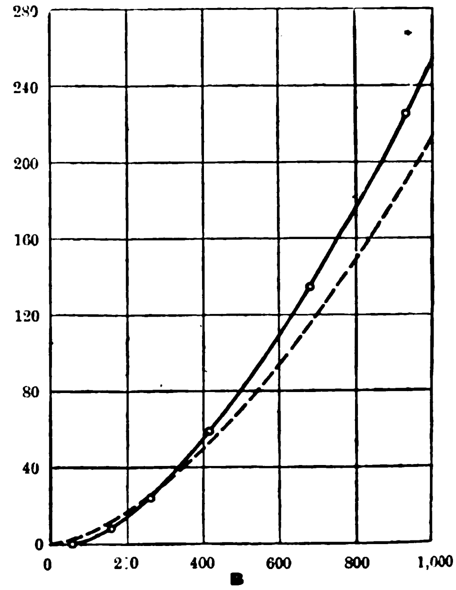

FIG. 23.—$\int H\,dl$ and B for the Low Cycles of Ring IV. The dotted line represents values of 0·0034 $B^{1{\cdot}6}$.

In further illustration of the point, we add a curve (Fig. 23), showing the actual values of $\int H\,dl$ in relation to B for the low cycles in the tests of Ring IV., and on the same diagram a dotted line is drawn, to show the value found for Mr. Steinmetz's formula, namely, $\eta B^{1{\cdot}6}$, the constant η being taken as 0·0034, since that value best accords with the tests of Ring IV. throughout the whole range of magnetisation. It will be evident from the diagram that this early portion of the curve is not even approximately expressed by the formula in question. The character and extent of the divergence is, perhaps, more obvious from inspection of the curve, than from comparison of the numbers which have been given above.

(To be continued.)

* *Phil. Mag.*, March 1887.

POWER TRANSMISSION BY MEANS OF HIGH-PRESSURE DIRECT CURRENTS.*

BY E. SCHULZ.

There are cases in which the use of series machines has distinct advantages over the employment of compound dynamos and shunt-wound motors, these residing chiefly in the fact that when used with high pressure the windings of the magnets have only to resist a small proportion of the total voltage instead of the whole; and

* Abstract from an article in *Elektrotechnische Zeitschrift*, March 8, 1894, p. 137.

Digitized by Google

in the case of shunt coils the danger of breakdown is intensified by the highly inductive nature of the windings. Other advantages of series machines are a more constant efficiency with varying load, greater torque, and a fixed position of the brushes. The author describes a few applications of the series machine, chiefly in cases when it is a question of one motor at the receiving end; he finds that practice confirms the theory. After calling attention to the transmission, at Frankfort, in 1891, of 20 H.P. at 1,300 volts from the Palmen Garten to the Exhibition, which was done by series machines, he goes on to a transmission plant at Geisa, in Thüringen. In this case a cork factory, five kilometres from the station (Hünfeld), finding that coal was doubled in price by the cartage, owing to the mountainous country, determined to utilise a disused mill-stream in its neighbourhood to supply the power required—some 20 H.P. A turbine by Briegleb Hausen and Co., of Gotha, regulated by hand, drives by bevel gearing a horizontal shaft, which in its turn drives the dynamo, giving 650 volts and 32 amperes at 700 revolutions, and taking at full load 32 H.P. The dynamo is four polar, series wound, and for regulating the speed of the motor has a rheostat in parallel with its fields. On the switchboard is also a safety device, consisting of an automatic short-circuiter for the fields, and no fuses are required. The line goes in a large arc of a circle up the mountain to the factory about 1,000 yards away; it is of bare copper wire 5mm. in diameter, and is carried on poles and telephonic porcelain insulators, being protected by lightning conductors; a third wire, of iron, is used for signalling purposes. The motor is wound for 600 volts and 24 H.P. at 650 revolutions per minute, and drives by shafting the whole factory. The starting is excessively simple; it consists merely in closing all the switches, and then starting the turbine, when dynamo and motor both start up gradually; the speed of the latter is very uniform. The loss in volts is 50, and the efficiency is 75 per cent. from the shaft of the dynamo to that of the motor, as was guaranteed; and the installation has been working since November, 1892, without a hitch.

A second case is that of a factory in Chemnitz, where some 200,000 gallons of water a day are used for dyeing purposes, and this is raised by a pump worked by a motor to the factory 80ft. above the pumping station, and about a quarter of a mile away. This factory supplies the power from its main countershaft to a series dynamo running at 1,000 revolutions, and giving 30 amperes at 300 volts, and taking 14 H.P. The safety arrangements and regulating apparatus are similar to those at Geisa. The switch of the motor at the pumping station is practically always on, and when water is required the dynamo is started, and the motor immediately follows its motion. This installation has run 20 hours a day since its erection in December, 1892. A similar case is to be found in the dye works of Herr O. Sattler, in Meerane, Saxony, where, however, the power required is very small, only about 3 H.P., but the distance is over a mile.

A very interesting example is in the brass foundry at Rodewisch. A 55-H.P. turbine drives a 53-H.P. series dynamo, by shafting and belts, providing at 600 revolutions per minute 70 amperes at 500 volts; this current is carried by bare copper wires 10mm. in diameter, through a distance of one kilometre to the receiving station, where the series motor, running at the same speed as the dynamo and giving 41 H.P., drives by ropes a counter shaft. A mechanical coupling enables a steam engine of 80 H.P., which drives other machinery, to be also geared to this shafting, so that the engine and the motor run in parallel; and this arrangement is perfectly successful. It cannot be done with a shunt motor, which is too sensitive, and either takes all the load, or none, and then reacts on its dynamo. The compound motor works better, but the starting is difficult. Series motors have the advantage that when running in one direction they cannot reverse the current and drive their dynamo. The motor and the engine work in parallel 11 hours a day, and the motor works alone for 12 hours; and there has been no hitch since the start in September, 1893. At starting the motor was loaded up to 80 H.P. by cutting off the steam of the engine; the motor drove all the machinery and no sparking was visible, the advantage of a fixed position of the brushes being very evident.

LEGAL INTELLIGENCE.

Thompson v. Cowles Syndicate Company (Limited).

In the Court of Appeal on Tuesday, before the Master of the Rolls and Lord Justices A. L. Smith and Davey, the hearing was commenced of an appeal from the judgment in this case delivered by Baron Pollock on November 14th last. (See *The Electrician*, November 17, 1893, p. 73).

Mr. FLETCHER MOULTON, Q.C., said the plaintiff (Mr. Thompson) sued the defendant Company for the price of certain carbons sold by him to them. The case was heard before Baron Pollock, who found for the defendants, and he (Mr. Moulton) now appealed from that decision. There was originally in the pleadings a counter-claim, which was abandoned at the hearing, so that the only question before their lordships was whether the plaintiff was entitled to recover the price of the carbons, the defence being that the carbons were not good carbons. There would be two questions in the case, one as to what the contract was, that is, what liabilities it carried with it, and, secondly, as to whether the alleged breach was proved. The carbons were used in the process of electrically obtaining aluminium. The carbon rods were tied together in bundles, and used as conductors to convey the current into the bath and to convey it out again. It seemed to him most important that their Lordships should see the way the contract was made, in order to get at an understanding of what it was they really undertook to furnish. They (the plaintiff's side) said what they furnished were perfectly good. There was no question about their being anything but pure carbons, and there was no warranty of any kind. They were delivered, and the defendants worked with them, but they found that they gave them some trouble, so they did not continue to purchase them, and refused to pay for those which they had purchased.

The MASTER of the ROLLS: What did the judge hold?

Mr. MOULTON: That there was no warranty; but it seems to me that he also held that the purpose to which they were to be applied was a known purpose, and that they must be commercially fit for that, and then he held, I think by mistaking the evidence, that we sent something which was not that which we were supplying to other people for the purpose. We sent them a sample, quoted for carbons according to that sample, and sent carbons exactly like that sample. That is not contested. We sent carbons similar to those supplied to a firm doing the same thing for five years. I submit that the alleged failure was not a failure due to any defect of the carbon at all.

The MASTER of the ROLLS: What did the judge find?

Mr. MOULTON: He found that these were not suitable carbons for use in the aluminium process. Continuing, Mr. Moulton read the correspondence between the parties, showing that an offer was made and sample sent in 1891; attention was re-directed to this quotation in May of the following year, and an order was ultimately given.

The MASTER of the ROLLS, quoting a phrase in one of the letters, "of similar make to sample forwarded," said that did not constitute sale by sample.

Mr. MOULTON thought it was something very near it. Resuming his argument Mr. Moulton said he would pass on from his first point to the performance of the order. The plaintiff was the agent for a French manufacturer, M. Berne, to whom the order was passed on. That gentleman wrote saying that 3,000 kilos of carbon would be sent off in two qualities, so that the Cowles Company might make tests and choose which they preferred, and then the remaining 7,000 kilos to complete the order would be sent in accordance with their selection. That letter expressed the intention of M. Berne at the time of writing; but, as a matter of fact, only one quality of carbon was sent, and that was the same quality as the sample, and the same as that which had been supplied to the Swiss Aluminium Reduction Company in large quantities. He could not see why so much importance was attached to this letter. It was not as if one quality was to be cheaper than the other, or in any way different from the other, except that one might suit the particular mode of working of a customer better than another. As a matter of fact, however, that intention was not carried out, as would be seen from M. Berne's evidence. Now he came to the complaint against these carbons. From January, 1892, the defendants had been using certain carbons supplied by an American firm, who had, he believed, set up their own plant, and they had had an American expert over, who had arranged the plant and taught them their business, and told them exactly what current to send through these American carbons. He thought it was 141 amperes that was sent through each carbon. They had never had any experience of anything but these American carbons, which were very hard and metallic in ring. It was said that the American carbons remained black above the bath, whilst when the plaintiff's carbons were used they got red-hot, and wasting set in. They took the plaintiff's carbons, and used them with the same current as they had been using for the American carbons, making no experiments to find what was the proper composition of the bath or what was the proper current to send through them. They just did the same as they had done with the American carbons. What happened was this: Plaintiff's carbons got tremendously hot, so hot that they wasted away, because the air attacked them. They carried out the process in an open cistern, instead of covering in the cistern to exclude the air, and so prevent the wasting. The defendants said, "What your carbons did not do the American carbons did, and therefore yours are bad, and the Americans are good."

The MASTER of the ROLLS: Were yours cheaper than the American?

Mr. MOULTON believed they were a little dearer. Plaintiff replied, "It does not follow at all that ours were worse carbons than the American." There were only about four people in the world who did this difficult process, so that there was no "ordinary method" in the usual sense, and the best way of using particular carbons could only be determined by experiment. The plaintiff's contention was that they must have had the bath a great deal hotter when his carbons were used than when the American carbons were used; they must have done so from the very fact that in one case the carbons remained black, whereas in the other they got red-hot, for they had ascertained that their carbons were quite capable of taking a current of 142 amperes, and to have been used without getting even too hot to hold in the hand. Therefore, the failure was from no fault of the carbons. It might, indeed, be because the carbons were too good.

Lord JUSTICE DAVEY: You say they ought to have used a current adapted to the particular carbon; that they ought to have found out what was the right current for that particular kind of carbon?

Mr. MOULTON: That is my point, my lord.

Lord JUSTICE A. L. SMITH: You must admit there was the bargain to supply carbons for smelting.

Digitized by Google

Mr. MOULTON: Carbon electrodes, I quite agree. But these are only big sticks of well-made carbon. You may use them in any way you like. They are sometimes used for the Cowles process.

The MASTER of the ROLLS: You must have known the particular purpose for which they were required.

Mr. MOULTON: We did, so much so that these were the things which we used to supply to the Swiss Company for the same purpose.

The MASTER of the ROLLS: It seems to me that you did not warrant at all that they should answer a particular purpose, but you did that they should be a merchantable article.

Mr. MOULTON: Certainly.

The MASTER of the ROLLS: The judge seems to have put you in the most favourable position as regards the contract, but to have found that you supplied articles which were not merchantable.

Mr. MOULTON: That they are merchantable carbon rods for use as electrodes in smelting there is no doubt. The only evidence of inferiority, and the only evidence at all of their not being merchantable, is the failure, without previous experiment of any kind.

The Court then rose for the day.

WEDNESDAY, APRIL 11TH.

When the Court resumed on Wednesday morning, after a consultation between the parties, Mr. Moulton said Mr. Bousfield and himself had considered the matter, and had arranged a settlement. The appeal would therefore be withdrawn.

Meux's Brewery Company v. City of London Electric Lighting Company; and Shelfer v. City of London Electric Lighting Company.

This was an action, the hearing of which was commenced before Mr. Justice Kekewich yesterday, for an injunction against the defendant Company to restrain them from so running their central electric lighting station at Bankside as to be a nuisance and a danger, and £10,000 damages were claimed.

Mr. Warmington, Q.C., Mr. Badcock, and Mr. Waight represented the plaintiffs, and for the defendants Mr. J. Fletcher Moulton, Q.C., Mr. Renshaw, Q.C., and Mr. Braithwaite appeared.

Mr. WARMINGTON, in opening, stated that the plaintiff's premises, the Waterman's Arms, Bankside, adjoined the electric lighting station of the defendant company, and since the works of the latter had commenced, the noise and vibration had become almost intolerable, whilst fissures had been developed in the walls of the house to such an extent that it was possible to push a stick or foot-rule right through the wall.

Mr. SEWELL, a surveyor, produced plans of the premises, and described his observations upon the occasion of several visits. On the 23rd of October, 1893, he first visited the plaintiff's house. On approaching it, walking along Bankside, he heard a considerable humming and thumping noise coming from the defendants' works, and felt an accompanying vibration. On the first floor of the Waterman's Arms the windows were rattling very much, and in the south-west angle (that nearest the defendant company's premises) there was a crack having the appearance of newness. This crack extended nearly the whole height of the room, was from a quarter to a half-an-inch in width, and went right through the wall. There was also a crack in the ceiling. In the room on the floor above there was a continuance of the crack in the wall, but it was wider, being over an inch in width. This also extended right through the thickness of the wall, eighteen inches, and he could push his foot-rule through. In this room the roof and the party-wall had parted company, and he could see daylight through the ceiling. The cracks on this floor also appeared to be new. He made a second inspection a few days later in company with Mr. Chatfeild Clarke, the defendant Company's surveyor. This was about half-past four in the afternoon, and although the vibration and noise were still distinguishable, they were not so pronounced as upon the previous occasion. He had gone to the house several times since, and found that the cracks had all spread and opened more. As the result of tests he had made, he was able to say that the vibration and noise were greater when the engines nearest the plaintiff's premises were running, and greatest when a number were running, but at different rates of speed—when they were not in step. He attributed the cracks, in the first place, to the fact that the defendants' pumping water out and making the foundations for their new premises caused Sir William Rose's house, which was on the other side of plaintiff's premises, to settle considerably towards the west side, pulling over the west wall of the plaintiff's premises, which were tied to it. The increase in the extent of the cracks was caused by the vibration consequent on the working of the defendants' engines. There were indications in the plaintiff's house of an original settlement towards the east, and the effect of the operations of the defendant Company had been to pull the west wall over in the reverse direction, and, therefore, to cause and increase the fissures.

When the Court rose for the day it was agreed that the cross-examination of the witness should be taken on Tuesday next, April 17th.

Parker v. London Metallurgical Company (Limited).

Mr. Justice Williams, in the High Court of Justice on Wednesday, gave judgment upon a summons issued by Mr. Thomas Parker for an order that his name might be struck off the list of contributories.

His LORDSHIP said that the applicant was not the allottee of the shares, but merely the transferee of Mr. Tremenheere, and the question was whether the latter had paid for the shares in cash. In order to constitute payment in cash, as distinguished from accord and satisfaction, it was necessary that there should be two debts payable *in presenti*, and that the Company and the person taking the shares should agree that an equal amount of the one debt should be taken in discharge of an equal amount of the other debt. When Mr. Tremenheere took his 100 shares there was a debt of £1,000 due from him to the Company. At the same time he was a creditor of the Company in respect of a loan of £1,000. That loan was to run for twelve months, unless he elected to take the shares set apart for him; in case he did so elect, the loan was to become immediately repayable, and he was then to be entitled to extinguish the £1,000 debt on the shares by setting against it the £1,000 due by the exercise of his option on the loan. He did exercise this option, and the Company thereupon credited him with the amount due on the shares and themselves with the payment of the loan. This transaction amounted to an immediate payment, and was not a mere contract as to something that was to be done *in futuro*. Mr. Parker, as transferee of Mr. Tremenheere, was therefore entitled to have his name removed from the register.

Chadwick v. the Woking Electric Supply Company (Limited).

A motion for judgment in a debenture-holder's action was made before Mr. Justice Stirling on Saturday last. The Company had issued 60 debentures of £50 each, and six of £500 each, and there had been default in payment of the interest. The principal thereupon became due and payable. Counsel explained that the receiver appointed in the action had entered into a provisional contract with certain persons for the sale of the whole business as a going concern, and, under these circumstances, his Lordship made an order for the usual account of the amounts due on the debentures, and an inquiry as to priority, with liberty to apply in Chambers as to the realisation of the property.

CORRESPONDENCE.

"IRON TESTING."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In answer to the letter in your issue of March 23rd from the Manchester Edison-Swan Company (Limited), as to our method of testing iron, we may say that we ascertain that the induction is equal in both cores by observing whether the voltage across the terminals of each coil is the same. It, indeed, is obvious that with iron cores of medium permeability that practically the whole magnetic resistance lies in the air gap, hence, with similar cores of iron the inductions are necessarily equal; however, this is practically verified as follows:—

The two coils are in series, and, therefore, have the same current, and, as the resistance of the coils is small, the voltage being equal, shows that the inductions are equal, or rather that the total number of lines is the same, and as the cores have the same cross-section, the inductions are equal.

It seems obvious that, since the total number of lines passing through a coil of small resistance is proportional to the E.M.F. on the coil, by varying the cross-section of the core the induction can be varied, and that this is correct is shown by the rate of increase of temperature varying with the cross-section of the core.—Yours, &c.,

Heaton Works, Newcastle. C. A. PARSONS AND CO.

THE HERMITE PROCESS AT WORTHING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to Dr. Kelly's report on the above, which you noticed in your last issue, permit us to point out that in our opinion the samples submitted to Drs. Klein and Dupre were not fair samples of the treated sewage, and that our view was supported by several members of the Worthing Town Council at their meeting last Tuesday. As a consequence of this feeling, the Council decided to consider the report as confidential, and not to adopt it or print it until it was confirmed by the investigations now being undertaken by the British Institute of Preventive Medicine. Unfortunately, Dr. Kelly had, on his own responsibility, allowed a large number of copies of the report to be distributed throughout the country. As you have given publicity to the report, we rely on your sense of fairness to give equal publicity to our protest.—Yours, &c., PATERSON AND COOPER.

European Works, Pownall-road,
Dalston, London, N.E., April 9, 1894.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *March* 30, 1894.

Telephone Matters.—The expiration of the Bell telephone patent has been followed by the creation of numerous companies for the establishment of telephone exchanges in rivalry with those of the licensees of the Bell Company, but thus far little or no headway has been made. This is as might have been expected, for aside from the difficulty of now successfully competing with the established exchanges is the continued monopoly by the Bell Company licensees through the Berliner patent of all forms of transmitters, and of all the fundamental switchboard patents. There is no immediate prospect of the trial of the Government suit of some years standing against the Bell Company to annul its transmitter patent for fraud and collusion. The Bate Refrigerator case, also affecting valuable telephone patents, has been argued, and is now in the hands of the judges for decision. Owing to the important character of this case, however, it is thought that the Court of Appeals may certify it to the Supreme Court for a decision that will be thus final.

Education of Electrical Engineers.—An examination of the registers of various colleges and technical schools in the United States shows that there are now about 1,500 students in the different courses of electrical engineering, and the numbers in the several classes also show that the attendance is rapidly increasing. Great stress seems to be laid upon the design of electrical apparatus, although the graduates of the present year would probably be sufficient to provide a dozen designers for each position of the kind in the entire country—all of which it is needless to say, are now filled. In addition, owing to the great reductions in the technical staffs of all the electrical companies during the last year, which reductions will in most cases be permanent, there are now several scores of electrical engineers of experience and proven competency to draw on to fill vacancies in the remunerative positions as they occur, thus still further narrowing the chances of graduates at the present time. It is unnecessary to explain that this state of affairs is largely or entirely due to the popular delusion that "electricity is only in its infancy."

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Corporation of Leeds having become owners of the tramways throughout the city, invite tenders for working the same under conditions which are partly set out in an advertisement appearing elsewhere, and of which conditions of letting, &c., may be obtained on application to Mr. John Harrison, town clerk, Town Hall, Leeds. Tenders have to be in not later than May 5th.

——— The Southampton Harbour Board require tenders for the work comprised in the lighting by electricity of the Town Quay, Southampton. Particulars can be obtained of the engineer, Mr. J. G. W. Aldridge, 9, Victoria-street, London, S.W.; and of 23, High-street, Southampton. Tenders have to be delivered to Mr. A. H. Skelton, clerk, the Harbour Board offices, the Town Quay, Southampton, not later than May 8th. Further particulars will be found in our advertisement columns.

——— The Council of the Borough of Brighton invite tenders for the supply and erection of Willans engines, continuous current dynamos, pipe work, spare armatures, &c. Further particulars are given in our advertisement columns, and all information can be obtained of Mr. F. J. Tillstone, Town Clerk, at the Town Hall, Brighton. Tenders have to be in by 10 a.m. on the 30th inst.

——— Messrs. C. H. Glover and Company, timber merchants, of Ormside-street, Old Kent-road, invite tenders for an electric jib wharf crane. Particulars will be found in our advertisement columns.

——— The Visitors of North Wales Counties Lunatic Asylum invite tenders for the construction and maintenance for a period of five years of a telephone between the asylum and Glanywern Hall, a distance of about three miles. Particulars of Mr. Barker, clerk to the Visitors, Denbigh.

TENDER INVITED.—*Extension of Time.*—The Edinburgh Corporation have extended the time for sending in tenders for the erection of the buildings, &c., on the central electric lighting station at Torphichen-street. Tenders must now be in not later than 10 a.m. on Tuesday next.

TENDERS ACCEPTED.—The Edinburgh Corporation have accepted tenders for the supply of cables in connection with their electric lighting scheme from W. T. Henley's Telegraph Works Company (unarmoured cables), the India Rubber Company (arc lighting cables), Messrs. Siemens Brothers and Co. (armoured cables).

PLANT FOR SALE.—Our advertisement columns contain particulars of an extensive plant for disposal, consisting of Marshall boilers, Armington-Sims engines, E.P.S. cells, &c., which is all in excellent condition, and of which particulars and cards to view can be obtained from Mr. H. Cuthbert Hall, A.I.E.E., 46, Queen Victoria-street, E.C., who will receive orders for the plant up to April 30th.

APPOINTMENTS.—Mr. Edgar Mapple has been appointed resident working electrical engineer to the Blackpool Corporation at a salary of £117 per annum.

——— Lieutenant A. H. Dumaresq has been appointed assistant instructor in electricity at the School of Military Engineering, Plymouth, *vice* Captain A. M. Stuart.

——— Mr. Harold W. Couzens has been appointed Engineer-in-Charge at the Corporation Electric Light Works, at a salary of £120 per annum.

——— Mr. A. J. Lawson, M.Inst.E.E., has been appointed Engineer and Manager of the County of London and Brush Provincial Electric Lighting Company (Limited).

LIQUIDATIONS.—The Official Receiver and Liquidator of Newington, Priddle and Co. (Limited) has called a meeting of the Committee of Inspection for Thursday next to consider a proposal to make a call on all the contributories of the Company of £1 per share.

——— A petition was presented for the winding up of the South Staffordshire Tramways Company (Limited) by shareholders, on Wednesday, and a legal objection that a company incorporated by Act of Parliament could not be wound up on a petition presented by a shareholder was overruled by Mr. Justice Williams, who considered that there might be some benefit to the shareholders in winding up, as there was apparently a surplus to be divided. As, however, charges of fraud had been made, it would be necessary for further evidence to be produced, and the hearing of the petition was accordingly adjourned.

ELECTRIC TRACTION.—The *Financial Times* of April 11th contains an article dealing with electric *versus* steam traction, from which very favourable anticipations are made of the results of electrical working by lines now in course of construction or in contemplation. The deductions made by the writer treat the City and South London line as a pioneer line, built under disadvantageous dividend-earning conditions, but serving to show the difficulties to be overcome and errors to be avoided in the construction of future electric lines.

DUPLEX UPRIGHT TUBULAR BOILERS.—Messrs. J. Weeks and Co., of King's-road, Chelsea, S.W., send us a circular containing a variety of testimonials from users of their patent duplex upright tubular boilers. The testimonials are of a decidedly appreciative character, and all bear date 1894, showing at a glance the established reputation of Messrs. Weeks and Co.'s boilers. Amongst the users are the Zoological Society of London, the Duke of Rutland, the Earls of Radnor, Lisburne, Sandwich, and Derby, and the owners of a large number of the principal private gardens throughout the country.

NEW FIRM.—Mr. Cathcart, late partner in the firm of Cathcart, Peto and Radford, has commenced business under the title of C. H. Cathcart and Co., at Dorset-buildings, Salisbury-square, Fleet-street, E.C.

MESSRS. DRAKE AND GORHAM.—This firm have received instructions from the Earl of Derby that the lighting of Derby House is to be entirely remodelled. The installation will consist of about 400 lights.

MESSRS. RASHLEIGH PHIPPS AND CO.—Amongst the contracts recently obtained by this firm are the lighting of Mr. George Grossmith's house, Dorset-square, London, and Earl Fingall's house in South Audley-street. The firm are also putting in a complete electric lighting plant at Mr. Rattray's mansion at Bear Hill, Twyford.

ELECTRIC COOKING AND HEATING.—The London Electric Supply Corporation (Limited) announce that an exhibition of electric cooking and heating apparatus manufactured by Messrs. Crompton and Co. is now on view at the Corporation's show room, Belgrave Mansions, Ebury-street, S.W., where demonstrations will be given every Thursday from 3:30 to 5 p.m. The series of demonstrations commenced yesterday (Thursday). The apparatus is always on view between 11:30 a.m. and 7 p.m.

Digitized by Google

Rabbidge Telephones.—Many years ago the India Rubber Company were makers of and supplying Silvertown telephones, but at that time the commercial importance of this instrument did not look promising, and the Company allowed the telephone industry to pass into other hands. A new departure has now been made. We have received a price list of the Rabbidge patented telephone, made and supplied by the Company. This telephone is designed for speaking over short lengths, and is specially adapted for offices, warehouses, and in groups of buildings. It is very simple in construction and convenient in manipulation, occupies very little space, and its articulation is loud and distinct. The receiver and transmitter, as well as the call and switch, are contained in one piece, similar in form to the microtelephone, having the receiver at one end to be placed to the ear, and the transmitter at the other to be held near the mouth. This piece is connected by a flexible cord to a plug placed in a wall block (as shown by the illustration), which also bears a small peg on which the telephone is hung. A and B in the illustration show the two plugholes required when only two offices are connected. When out of use the wall block (about 2¼in. in diameter) can be screwed to the side of a desk, and the instrument can be used without the operator leaving his seat. No call bell is necessary, but instead a small vibrating reed is placed in the receiver, which, when the battery is applied, gives a clear whistling note. The usual wall switch is replaced by a tube of mercury in the handle of the telephone, which automatically changes the connections when the telephone is brought into a position for speaking. The transmitter consists of loose carbon granules, which prevent the tendency to "pack," as each time the telephone is inverted the granules fall from one side to the other, and lie loosely in the cell. No permanent magnet is used, and no induction coil, the current being derived from the battery in direct circuit through both receivers and transmitters. The battery recommended for use is four Leclanché cells, preferably the No. 2 sealed agglomerate block form; No. 1 size may be used where the work is constant, or where a large number of instruments are connected. The Rabbidge telephone, being manufactured by the Silvertown Company, it is unnecessary to say that good workmanship may be relied upon.

Messrs. John Bolding and Son (Limited).—Mr. John Bolding informs us that he has registered his business of brass founder and manufacturer as a private limited company, his reason being to give his employés a pecuniary interest in the business, which will be conducted as hitherto under his personal superintendence and management. No shares will be offered to the public, all the shares being held by Mr. John Bolding and the employés.

"The Journal"—Part 110 of the *Journal of the Institution of Electrical Engineers*, price 3s. 6d., is now ready, and can be obtained of Messrs. E. and F. N. Spon, 125, Strand, London, W.C.

Ayr.—The Borough Engineer has presented a report, in which it is proposed to provide a preliminary supply of 4,600 private lights, and 15 2,000 c.p. arcs, to replace 95 gas lamps in the streets. He estimates the total initial cost at £11,000, the annual up-keep at £1,641, and the revenue from 3,000 private lights at £1,650. It was subsequently agreed to invite Mr. Robert Hammond to examine and survey the borough, and to report generally on the electric lighting question.

Bedford.—The deputation recently appointed by the Corporation has waited upon the Board of Trade, and was accompanied by representatives of the Bedford Electric Light Company and representatives of the Bedford Ratepayers' Committee. After hearing Mr. Sydney Morse on behalf of the Company, Mr. Coward on behalf of the Corporation, and Mr. Roff for the Ratepayers' Association, Sir Courtenay Boyle said it was clear that there was not a concensus of opinion in Bedford as to what was best to be done, and this was one of the cases in which the decision of the Board of Trade should be at once communicated. The Board of Trade were glad to develop trade by facilitating the efforts of such companies as the Bedford Company, but the primary object must be the benefit of the ratepayers, who were in the first place represented by the Corporation. The Bedford Corporation had had an Electric Lighting Order since August 4, 1890, and had done nothing under it, but the time when some definite action must be taken by them appeared to have arrived. His (Sir Courtenay's) advice to Mr. Mundella would be that if the Corporation would pass the necessary resolution for resolving to carry out the supply of electricity within the area covered by their Order, their assent to the application of the Bedford Company would not be dispensed with. If the Corporation would not consent to proceed with their Order, then the Board of Trade would dispense with their assent to the Company's application. In the event of the Company obtaining the powers asked for, the area to be supplied would be matter for reconsideration. There was no reason to suppose that the Company could not amply satisfy the Board of Trade as to their ability to carry out the conditions of the Order, and this would have to be done within the prescribed time; meanwhile the Corporation's Order would not be revoked in order that they might have an opportunity of dealing with the subject. The matter, therefore, was one in which the Corporation had the power to carry out the Order already obtained, and if this were done the Company's application would not be granted, but unless the Corporation moved at once, the Company's Order would receive the assent of the Board of Trade.

Bootle.—The Town Council have resolved to light the public offices by electricity, and are advertising for tenders. It is anticipated that the expense will be about £500 per annum, and a saving of about £40 on the gas bill is also expected. £3,600 is to be borrowed to recover the cost, subject to the sanction of the Local Government Board.

Bradford.—Complaints have been received from time to time by the Gas and Electricity Committee of the Corporation as to the lighting of the out-townships in the district, and a sub-committee has been appointed to consider the best means of placing the townships of Heaton and Allerton, and other smaller districts, on equal terms with the rest of the borough as to lighting facilities.

Bristol.—The Council of the Bristol Chamber of Commerce has just issued its report, in which reference is made to electrical matters. Satisfaction is expressed at the outcome of the agitation made by the Associated Chamber of Commerce, by which 22 lighthouses on the British coasts have been connected with the shore by electrical communication, including Lundy Island, the usefulness of which has been clearly demonstrated during the recent winter storms. In reference to the extension of the telephone system, the report states that in 1891 the number of subscribers to the Bristol Exchange was 562, which has increased up to the early part of 1894 to 800, in addition to 250 private lines. Reference is also made to the importance of the extensive installation of the electric lighting works put down by the Corporation, and which is now supplying current throughout the district. The Industrial Exhibition held at Bristol is declared a financial success from every point of view.——An extraordinary meeting of the members of the Bristol Tramways and Carriage Company has been held, at which formal approval has been given to the promotion of a Bill, now before Parliament, authorising the Company to make additional tramways. In reference to the threatened opposition from frontagers in West-street, the Secretary stated that, seeing that all conditions of the Tramways Act were fully complied with in the Company's proposed Bill, it was unlikely that the opposition would have any success.——The Local Board of St. George at their meeting last week received a statement from the chairman as to the objections raised to the electric railway scheme. He said that from interviews with the objectors they seemed bent upon opposing the measure, although the statutory amount of road space was properly provided for in the Tramways Company's Bill. The original number of objectors was three, but on solicitation being sent round this number had been increased.

Buckingham.—The local gas company has decided to light all the lamps or none, and is "jibbing" at a contract which has been given to Messrs. Parr and Gillies to light some of the public lamps by electricity. The Town Council appear disposed to extend the electric lighting contract, and the local gas company may have reason to regret the position it has taken up on the subject.

Burton.—The Municipal Offices Committee have presented a report to the Town Council, in which it is proposed to introduce the electric light into the municipal buildings at an expenditure of not more than £997. 13s. This expenditure was approved.

Chelsea.—The Chelsea Vestry have had before them the important question of the property in pipes laid for electric lighting cables, and subsequently disused. In 1889 the London Electric Supply Corporation laid some iron pipes from Knightsbridge through to Draycott-place, and for a short time supplied electricity to houses in the vicinity, but, subsequently, the cables were withdrawn, and the pipes are now empty. The National Telephone Company asked for permission to use these pipes for their telephone wires, and this proposal Mr. T. W. E. Higgins, the Surveyor to the Vestry, recommended should be approved. A member of the Vestry expressed his opinion

Digitized by Google

that through disuse by the original company the pipes became vested in the local authority, and it was ultimately decided that the Surveyor should inquire into the legal position and report.

CLONTARF.—At a meeting of the Town Commissioners, their approval was sought to the proposed electric tramway between Clontarf and the Hill of Howth, to be constructed by the Clontarf and Hill of Howth Tramway Company (Limited). After hearing the views of a deputation which waited upon them, the Commissioners adjourned the discussion on the subject to a special meeting to be held to-morrow (Saturday).

COLCHESTER.—The Public Library Committee of the Town Council will discuss at their next meeting the advisability of lighting the new Public Library by electricity.

DARLASTON.—The Local Board have agreed to the appointment of a special committee to consider the drawing up of a report to the Local Board on the subject of electric lighting.

DUBLIN.—Complaints have recently been made by subscribers to the National Telephone Company's system that undue preference is being given to new subscribers over those who had been subscribers to the Telephone Company of Ireland, whose business the National Company recently acquired. This has led to a correspondence, in which Mr. V. B. Dillon, Lord Mayor of Dublin, who is also a member of the Local Board of the National Company, points out that since the acquisition of the Irish Company's business the National Company have laid out large sums in improving the Dublin service, representing a total outlay of £20,000. The National Company had also decided to reduce the ordinary £12 exchange rental to £10 to subscribers entering into a five years' agreement, retaining the £12 rental for those who preferred the regular annual subscription. This arrangement having met with some opposition from many of the old subscribers, it has now been decided to make the rental £10, withdrawing the five years' condition. This brings to a satisfactory termination a state of affairs which has caused considerable agitation amongst the Company's subscribers in Ireland, who agree that since the transfer a great improvement in the service has resulted.

EALING.—The contractors for the electric lighting of this district have notified the Local Board, through their surveyor, that the Board will be in a position to deal with the question of private lighting, and, in fact, with the whole of the electric lighting of the district, by the beginning of August. Applications for a large number of lamps had already been received, showing that for private lighting the Board might expect an increasing demand for the electric current.

EDINBURGH.—Mr. Monkhouse, the Corporation's resident electrical engineer, has now assumed duty, his temporary official quarters being at the City Chambers. He has recently prepared a set of rules, which the Corporation are now issuing, to be observed by contractors in wiring houses to be supplied with the electric current.——The Corporation have taken counsel's opinion on the question of their agreement with Messrs. Dick, Kerr and Co. for the tramway rights. Mr. Cripps, Q.C., advises that the Corporation must not on any account allow the matter to pass this time without taking action. Generally the opinion is adverse to Messrs. Dick, Kerr and Co.'s arrangements.

FAREHAM.—At a meeting of the Local Board a letter was received to the effect that at the annual meeting of the shareholders of the Fareham Electric Light Company a resolution was passed authorising the Directors to offer their business to the town authorities. The letter was from Mr. Blake, who therefore offered the whole of the buildings, plant, machinery, mains, apparatus, &c., which the Company have installed, and for which they possess a Provisional Order for a term of 42 years from 1892. It was proposed by the Chairman of the Board that the proposal should be placed before a general meeting of the ratepayers, and this is to take place on the 25th inst.

FIRE AT NORTH WOOLWICH.—A disastrous fire occurred on Wednesday evening at the extensive works of the Fowler-Waring Cables Company at Henley-road, North Woolwich. The fire was first observed at 7:15, and commenced in the insulation room, which was entirely destroyed. The stock is damaged to the extent of between £5,000 and £6,000. The Fowler-Waring Company is very busy, but we are glad to say that little or no inconvenience will arise from the fire, and only a trifling delay will be occasioned by the disaster, which will temporarily throw out of employment a small number only of the Company's employés. The damage is fully covered by insurance.

GUILDFORD.—The Board of Trade have intimated that they propose to dispense with the consent of the Corporation to the Provisional Order applied for by the Holloway Electric Supply Company for lighting Guildford and district by electricity. If the Corporation wish to have any clause inserted whereby they can acquire the undertaking previous to the expiration of the 42 years' limit inserted in the Order, the Board of Trade are prepared to give the matter their consideration. The subject was dealt with at the last meeting of the Town Council, when it was decided by a small majority to ask the Board of Trade for power to purchase on statutory terms after 30 years, instead of the 42 years' limit provided in the Company's order.

GREAT MISSENDEN (BUCKS.).—Messrs. Habgood and Smith gave, last week, an interesting demonstration of electric heating and cooking, the plant being kindly lent by Messrs. Crompton and Co. for the purpose. The electric lighting of the village is progressing favourably, and many applications have been received from private consumers.

THE HARTLEPOOLS.—The Town Council have discussed the subject of electric trams, and have approved certain provisions and conditions set out by the promoters of the electric tramways in the city.

LIVERPOOL. — At a general meeting of the members of the Junior Reform Club, which was largely attended, it was unanimously resolved that arrangements should be made forthwith for the installation of the electric light throughout the Club's premises.

LONDON COUNTY COUNCIL.—A motion that the footways of the Victoria Embankment be widened in order to allow the electric light standards to be placed on the sides of the carriage-way has been approved. It has also been agreed that the Highways Committee consider and report to the Council on the feasibility of providing for the lighting of Westminster and Waterloo Bridges by electricity, apart from the question of the electric lighting of the Victoria Embankment.

MONTROSE.—The report of the deputation appointed to visit Edinburgh, Coatbridge, and Glasgow in connection with the electric lighting scheme is to be presented at the next meeting of the Police Commission.

MIDDLESBROUGH.—The Electric Lighting Committee of the Town Council have appointed a deputation to visit Halifax and Bradford, and to extend their visit to Huddersfield if necessary, to inspect the electric lighting plant laid down at these places, and to obtain information and report to the Council.

PERTH.—A proposal has been made by the local gas company to fit up the Town Hall for the electric light, and to supply a number of arc lamps for the street lighting. The gas company's tender for lighting the Town Hall for £106. 15s. has been accepted; 80 lights are to be provided.

POPLAR.—In reply to a question asking when Mr. Preece's report would be received regarding the electric lighting of the Poplar district, the Clerk to the Board of Works replied that Mr. Preece had been very ill, but that it was hoped that his report would be received in a few weeks.

PRESENTATION.—At Brighton, on Saturday last, Mr. G. J Philpott, late Chief Engineer of the Brighton and Hove Electric Light Company, was presented with a gold watch and chain as a *souvenir* of his connection with the Company, and as a mark of respect from those who had served under him. Mr. Philpott has joined Mr. Taylor at Croydon.

ST. OLAVE'S (SOUTHWARK).—The new offices of the Board of Works have now been completed. The building has cost £2,300 to construct, and has been lighted throughout by electricity by Mr Mackie.

SHIRLEY (HANTS).—The question of lighting their district by electricity is under the consideration of the Shirley and Freemantle Local Board, and at the meeting last week the General Purposes Committee were instructed to commence negotiations for the purchase of some disused factory premises in Mousehole-lane for a central lighting station.

SOUTHPORT.—The New Infirmary Committee have reversed a decision come to three weeks ago, and have decided that, at any rate for the present, the electric light shall be used in all the wards and rooms of the institution, and that the supply be obtained from the Southport Corporation's mains. As the production of electricity on the premises is now contemplated, the building committee was instructed to make the boiler house and chimney of ample dimensions.

SOUTH SHIELDS.—Since the appointment of Mr. J. A. Jeckell as borough electrical engineer, in November, 1893, the Electric Lighting Committee have considered the question of obtaining a suitable site for the central station, and have ultimately selected one known as the Low Foundry, which has been purchased for the sum of £4,400. The station will be on the river side, with a frontage of 125ft. This will enable the authorities to obtain coal at the lowest figure, and water for condensing will be almost costless, as, even at low tide, the water does not leave quay. The site has a total area of 2,500 square yards, and is very central.

STIRLING.—In connection with the intention of the Town Council to continue to oppose the application made by the Caledonian Electric Supply Company for a Provisional Order, a petition is to

Digitized by Google

be sent to the Board of Trade to the effect that if the Council have another opportunity they will themselves make an application for a Provisional Order. According to the latest intelligence, the Board of Trade have decided not to proceed with the Caledonian Company's application.

SUNDERLAND.—A Local Board inquiry has been held, at which the proposal to borrow £26,000 for electric lighting purposes was investigated.—— A proposal having been made that electricity should take the place of gas for lighting the Union workhouse, it was decided at the last meeting of the Board of Guardians that they should wait until the Corporation supplied them with the electric light, and this amendment was carried.

WATFORD.—Mr. Rogers, who is well known in connection with electric lighting matters in this town, has written to the Local Board inquiring what steps they propose to take in order to secure the electric lighting of the town. An electric lighting company was formed 18 months ago, with the Earl of Essex as Chairman, but at that time the Local Board stepped in, and announced its decision to itself apply for a Provisional Order, and still nothing has been done.

WEYBRIDGE.—The new contract entered into between the local authorities and the Weybridge Electric Supply Company (Limited) provides for the 119 public lamps being lighted at a charge of £2. 17s. 6d. per lamp per annum.

WOKING.—It is stated that Messrs. New and Mayne have secured the control of the Woking Electric Supply Company's business and works, and that it is proposed to put down improved machinery. About ten miles of cables are already laid covering a large area, and the anticipated demand for current justifies Messrs. New and Mayne in making considerable extensions in the near future.

WORCESTER.—The City Council have adopted a resolution to rescind a decision come to last year to erect at the waterworks Tangye engines and pumps and Galloway boilers, at an estimated cost of £1,960, and decided to accept instead a tender of the Brush Company to supply and fix two sets of electrical pumping plant at an estimated outlay of £1,128, and also a tender from the same company to lay mains capable of conveying the necessary current to drive the motors and to light 1,000 lamps, *en route* from Castle-street to the waterworks, at a further cost of £961.

COMPANIES' MEETINGS AND REPORTS.

Eastern Extension, Australasia, and China Telegraph Company (Limited).

The following is the report of the Directors of this Company for the half-year ended December 31st last, which will be submitted to the forty-first ordinary general meeting, to be held at Winchester House, Old Broad-street, E.C., on Wednesday, the 18th inst., at 2 o'clock :—

The gross receipts, including Government subsidies, have amounted during the half-year to £251,698. 10s. 6d., against £247,766. 19s. 1d. for the corresponding period of 1892. The working and other expenses, including £21,122. 4s. 8d. for cost of repairs to cables and expenses of ships, absorb £76.574. 15s. 6d. against £91,768. 18s. for the corresponding period of 1892, leaving a balance of £175,123. 15s. From this is deducted £4,015 1s. 9d. for income tax, and £31,895 for interest on debentures, debenture stock, and contribution to sinking fund, leaving as the net profit for the half-year £139,213. 13s. 3d., which, with £81,116. 17s. 8d. brought forward from the previous half-year, shows an available balance of £220,330. 10s. 11d.

One quarterly interim dividend of 1¼ per cent. has been paid for the half-year, and it is now proposed to distribute another of like amount on the 19th instant, making, with the interim dividends paid for the first half-year, a total dividend of 5 per cent. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year 1893. The balance of £107,830. 10s. 11d. has been carried to the general reserve fund, which, after being credited with interest received on investments during the half-year, now stands at £633,686. 2s.

The working of the Australian tariff arrangement for the third year of "Guarantee," ending 30th instant, is estimated to result in a loss of between £11,000 and £12,000, half of which will be borne by the Guaranteeing Governments, and the other half by the associated cable companies, in accordance with the terms of the agreement. This loss would, however, be far greater, but for the abnormally large traffic which was transmitted during a portion of the year in connection with the financial crisis in Australia.

In accordance with the provisions of the Trust Deed dated May 10, 1879, 371 of the Company's Five per Cent. Australian Government Subsidy Debentures amounting to £37,100 were drawn by lot on the 2nd instant for payment at par on July 2nd next. (The numbers are given in *The Electrician* of April 6th.)

With a view to carrying out the arrangements referred to at the last general meeting for increasing the security of the Company's China system, a contract has been entered into with the Telegraph Construction and Maintenance Company for the manufacture and laying of an alternative cable between Singapore and Hong Kong, connecting the island of Labuan and British North Borneo *en route*. The first section between Singapore and Labuan is now being laid, and the whole work is expected to be completed and the line opened for traffic before the end of the present month.

Your Directors have the satisfaction to report that the Netherlands-Indian Government have placed at the Company's disposal a special wire through Java for the transmission of the International traffic by the Company's employés, and a small station has been opened by the Company in the Government office at Sourabaya in connection with the same. This special wire gives the Company an efficient alternative communication to their Singapore-Banjoewangie cable.

Mr. Francis Augustus Bevan and Sir Albert J. Leppoc Cappel, K.C.I.E., are the Directors retiring by rotation, and offer themselves for re-election. The retiring auditor, Mr. Henry Dever, desires to offer his firm, Messrs. Deloitte, Dever, Griffiths and Co., for election as auditors to the Company. Messrs. Welton, Jones and Co., also retire, and offer themselves for re-election.

Indo-European Telegraph Company (Limited).

The following is the Directors' report to be presented to the general meeting to be held at Winchester House, Old Broad-street, E.C., on Thursday, the 25th inst., at noon. Holders of shares to bearer intending to be present at the meeting must deposit their shares at the offices of the Company before noon on Tuesday, April 24th.

The Company's revenue from all sources for 1893 amounted to £122.860. 10s. 4d., as compared with £117,479. 13s. 10d. for 1892, showing an increase of £5,380. 16s. 6d. The expenses were: on commercial and general account, £34,916. 5s. 11d. ; on maintenance account, £30,043. 11s. 7d.; total, £64,959. 17s. 6d., as against £62,148. 16s. 3d. for 1892, an increase of £2,811. 1s. 3d. Deducting the above expenses, taking credit for £7,557. 16s. 11d. brought over from 1892, and debiting income-tax, there remains the sum of £63,952. 3s. 8d. From this amount £15.000 has been placed to reserve, and that sum, together with £10.625 amount of interim dividend, have to be deducted, leaving a balance of £38.327. 3s. 8d. The Directors now propose the declaration of a dividend for the six months ending December 31st, of 17s. 6d. per share, making, with the dividend already paid, 6 per cent. and a bonus of 20s. per share, both free of income-tax, making in all 10 per cent. for the year, carrying forward £6,452. 3s. 8d. to the credit of 1894.

The Directors have to express their deep regret at the loss of the valuable services of their late colleague, Mr. Weaver, who died last September, and who had been connected with the Company since its incorporation. Mr. John von Berenberg Gossler and Mr. H. H. Meier retire from the Board by rotation, and, being eligible, offer themselves for re-election. The auditors, Messrs. C. F. Kemp, Ford and Co., public accountants, retire and offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

INTERNATIONAL ELECTRIC STORAGE (LIMITED).—This Company was registered on April 4th, with a capital of £200,000, in £5 shares, to purchase or otherwise acquire all or any of the shares, works, undertakings, business, property and liabilities in and of the Universal Electric Lighting Company (Limited) ; to acquire all or any of the letters patent of Messrs. Theryc and Oblasser for electric accumulators, granted to them in the United Kingdom and elsewhere ; to generate, produce, store, accumulate and distribute electricity and electromotive force ; to manufacture and supply electric locomotives, cars, motors, batteries, accumulators, distributing mains, &c. ; and generally to carry on the business of electricians, electrical and mechanical engineers, telegraphic and telephonic apparatus manufacturers, electrical appliance manufacturers, &c. The subscribers (with one share each) are : Major S. Flood Page, John L. Higgs, J. G. B. Elliott, James H. Mace, B. H. Van Tromp, Col. Ernest Villiers, and A. Schanschieff. The first Directors are : Major S. Flood Page, Messrs. Vaughan Cousins, John L. Higgs, James H. Mace, Charles Theryc, B. H. Van Tromp and Ernest Villiers.

STEEL AND GARLAND (LIMITED).—This Company was registered on April 5th, with a capital of £40,000, in £5 shares, to carry on the business of a manufacturer of and dealer in electric light fittings and general art metal work and brass aud iron founder, carried on at Sheffield and London.

WILLIAM ALLAN AND CO. (LIMITED).—This Company was registered on April 5th, with a capital of £50,000, in £100 shares, to purchase or otherwise acquire, and undertake all or any part of the business, goodwill, property, and assets of Messrs. William Allan and Co., of the Scotia Engine Works, in the borough of Sunderland, Durham, as from April 1, 1894. William Allan, M.P., is the Managing Director.

BOHM AND CO. (LIMITED).—The annual return of this Company, made up to February 19th, has been filed. The Company was registered on October 21, 1892, with a capital of £20,000 in £1 shares, to acquire the business of glassblowers and electricians, carried on by Ernest Böhm and Ernest B. B. George, at 42 and 43, Little Britain, London, E.C., and to carry on the business of glassblowers and workers, electrical and mechanical engineers, and manufacturers of electric, magnetic, telegraphic, and telephonic appliances and apparatus. 19.999 shares have been taken up, of which 19,992 were issued as fully paid to the vendors. Upon the remaining seven shares the full amount has been called, resulting in the payment of £1, leaving £6 in arrear.

MAZARRON ELECTRIC LIGHT COMPANY (LIMITED).—The statutory return of this Company, made up to March 14th, was recently filed. The nominal capital is £15,000, divided into 500 £8 per cent. cumulative Preference shares of £10 each, and 10,000 Ordinary shares of £1 each. All the Ordinary and 100 Preferred shares have been taken up, of which 9,995 Ordinary shares were issued as fully paid to the British and Foreign

Digitized by Google

Trading Company (Limited), of 175, Dashwood House, New Broad-street, London, E.C. The full amount has been called on the remaining 7 Ordinary and the 100 Preference shares, resulting in the payment of £1,007. The Company referred to above now hold 5,493 Ordinary shares.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED). The annual return of this Company, made up to February 26th, has recently been filed. 4,566 shares, out of a nominal capital of £50,000, in £10 shares, have been taken up, and a call of £8 per share made on 3,535, while a call of £6 per share has been made on the remaining 1,031 shares. This has resulted in the payment of £34,226, leaving £240 in arrears.

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY COMPANY (LIMITED).—This Company's usual annual return was recently filed, when 6,769 shares of £5 each, out of a capital of £50,000, were allotted. A call of £4 per share on 6,701 shares has resulted in the payment of £28,735 (which includes a sum of £1,931, which has been received in advance of calls), while 68 shares have been issued as fully paid.

PONTYPOOL ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company made up to March 18th, has been filed. Out of a nominal capital of £50,000, in £5 shares, 953 shares have been taken up. Upon 509 of these the full amount has been called, and upon the other 444 a call of £4 per share has been made, resulting in the payment of £4,341, which includes a sum of £20 paid on certain shares applied for but not allotted.

SCARBOROUGH ELECTRIC SUPPLY COMPANY (LIMITED).—The first annual return of this Company, made up to March 14th, has been filed. 2,450 shares of £10 each have been taken up, a call of £8 per share made, and the full amount of £19,600 received in respect thereof.

SMITH AND CHAMBERLAIN (LIMITED).—The annual return of this Company, made up to November 8, 1893, was recently filed. 1,528 shares, out of a nominal capital of £100,000, in £10 shares, of which 1,521 shares were issued, with £8 per share considered as paid. £8 per share has been called and paid on the remaining seven shares.

ST. JAMES AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to February 13th, has been filed. The nominal capital consists of 100 Founders' shares of £1 each, 19,980 Ordinary shares of £5 each, and 20,000 Preference shares also of £5, a total of £200,000. All these have been subscribed and allotted, and the full amount paid.

SUNBEAM LAMP COMPANY (LIMITED).—The annual return of this Company, made up to February 14th, has just been filed. Out of a nominal capital of £25,000, in £10 shares, 1,600 have been taken up, and of these 857 were issued as fully paid. Upon 455 of the remainder, £8 per share has been called, and the full amount has been called on 288 shares, resulting in the payment of £6,490, and leaving £30 in arrear.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—The annual return of this Company, made up to March 13th, has been filed. The whole nominal capital of £448,200, divided into 37,350 shares of £12 each, has been taken up, the full amount called, and all calls paid.

CITY NOTES.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend for the quarter ended 31st March last of 9s. per cent. on the Ordinary stock, and 18s. per cent. on the Preferred stock (less income tax), payable on May 1st.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—Notice is given that the eighth and final drawing of the Five per Cent. Debentures (1884 issue) of this Company—187 in number—will take place on the 20th inst. at the offices of the Company.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended April 8th were £852, as against £842 in the corresponding period of 1893, being an increase of £10. The total receipts for the half-year amount to £12,886, as against £12,856 for the corresponding period of 1893, an increase of £30.

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING COMPANY (LIMITED).—Letters of allotment for the first issue of 19,900 Ordinary shares in this Company are now being posted.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announces the payment by warrants, on May 1st, of interest for the half-year ending April 31st on their Four per cent. Mortgage Debenture Stock. The transfer books will be closed from April 27th to May 1st, both days inclusive.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company give notice of their intention to apply to the Board of Trade, under Section 6 of the Merchant Shipping Act, 1871, for an order to change the name of a vessel purchased by them for use as a telegraph steamer, from "Nentwater" to "Duplex." Any objection to the proposed new name must be sent in to the Marine Department, Board of Trade, by April 17th.

GREAT NORTHERN TELEGRAPH COMPANY.—The accounts are issued of this Company for the year 1893. The total receipts for the year, after deducting a loss on exchange of £42,275, and including a balance brought forward of £45,667, amounted to £352,975 against an expenditure of £77,793, leaving a balance available for dividend (after paying off 100 of the 1883 Five per Cent. Debentures, the payment of interest on the remainder, and the payment of interim dividends, which absorbs £95,250) of £179,932, out of which it is proposed to pay a dividend of 7s. 2d. per £10 share, taking £54,166, adding to the reserve and renewal fund £83,333, increasing the pension fund of the staff by £2,778, taking £1,500 for the remuneration of the Directors, and carrying forward £38,154 to next account. The reserve and renewal fund now amounts to £862,968, and the balance-sheet shows the investments on account of this fund, which are all of the gilt-edged description.

PETZOLD AND CO. (LIMITED).—It is notified that the whole of the debentures (£60,000) are now in course of being paid off at par. The English portion (£25,000) will be paid on presentation at the Crédit Lyonnais, 40, Lombard-street, E.C.

PHOSPHOR-BRONZE COMPANY (LIMITED).—The annual general meeting of this Company was held at the Bridge House Hotel, London Bridge, on March 30th (Mr. Henry Seebohm in the chair), when the Directors' reports and accounts were adopted. Mr. C. E. Taunton resigned his position as a Director, and Mr. Bernard Gibson was re-elected and Messrs. Francis W. C. Cumming and Richard E. M. Lagerwall were appointed Directors, the last named to be Managing Director.

SHEFFIELD ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—This Company invite applications for a new issue of 6,000 shares of £7 each, which will make up a total subscribed capital of £70,000. This new capital is required to supply mains in the residential districts of Ranmoor and Broomhill. The new shares, which will be subscribed for locally, are to rank for dividend along with existing shares as from December 31st last. The nominal capital of the Company is £98,000, in 14,000 £7 shares, and the Company has power to borrow on debentures £25,000.

SOUTHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual meeting of this Company was held at the offices at Southampton on Wednesday in last week, under the presidency of Mr. G. T. Harper, J.P., who said that the prospects of the Company were very encouraging. The loss brought forward from 1892 of £755 had been reduced by last year's profits to £185; and with the continued demand for the electric current, there was every prospect that by the end of the present year they would have arrived at a dividend-earning stage. More capital was, however, required to enable the Directors to cope with the new applications for the light, and he hoped that local investors would take up sufficient shares to warrant them in incurring necessary expenditure. Notice would shortly be given of the intention of the Company to apply for a Provisional Order. The report (which appeared in our last issue) was adopted.

SUBMARINE CABLES TRUST.—Notice is given that on and after April 16th the sum of £1. 15s., on account of the coupon due April 15th, will be paid by Messrs. Glyn, Mills and Co., 67, Lombard-street, E.C. Coupons should be left with the bankers four clear days for examination.

THE "TAPE."—The Stock Exchange Committee have recently decided to call upon the Exchange Telegraph Company to withdraw its tape machines from their "outside broker" clients, and this the Exchange Company have agreed to do. It is difficult to see what public service this meddling order of the Stock Exchange Committee will effect, as an outside broker wishing to deal at tape prices will have little difficulty in effecting his object by the aid of the telephone. The Exchange Company, however, may be considerable losers by the action of the Committee, as many of its clients are members of the outside broker fraternity. The Stock Exchange Committee in taking this feeble action proves its incompetence to deal with a matter of serious public importance, viz., the relationship existing between the outside broker and members of the Stock Exchange. For some years the Committee have issued a small advertisement warning the public that members of the Stock Exchange are not allowed to advertise for business. This warning note has been withdrawn, and the Stock Exchange Committee thereby leave the public at the mercy of a set of sharks whose nefarious practices have recently come so prominently before the public.

WESTERN UNION TELEGRAPH COMPANY.—The following is the report of this Company for the quarter ended March 31st, 1894:—The condition of the Company at the close of the quarter ended December 31st, 1893, was as under:—

Surplus October 1, 1893, as per last quarterly report...		$7,208,180 13
Net revenues, quarter ended December 31, 1893		1,493,094 33
		$8,701,274 46
From which, deducting for dividend of 1¼ per cent. paid January 15th	$1,185,011 25	
Interest on bonded debt	224,212 25	
Sinking funds	20,000 00	
		$1,429,223 50
Left a surplus January 1, 1894, of		$7,272,050 96
Surplus January 1st, as above		$7,272,050 96
The net revenues of the quarter ended March 31st instant, based upon nearly completed returns for January, partial returns for February, and estimating the business for March, will be about		1,050,000 00
		$8,322,050 96
From which, appropriating for—		
Interest on bonds	$223,737 25	
Sinking funds........................	20,000 00	
		243,737 25
		$8,078,313 71
It requires for a dividend of 1¼ per cent. on the capital stock issued		$1,185,000 00
Deducting which leaves a surplus, after paying dividend, of		$6,893,313 71

In view of the preceding statements, the Committee recommend the payment of a dividend of 1¼ per cent. on the capital stock of this Company on April 16th.—The dividend may be collected through any bank on or after the 16th inst.

Digitized by Google

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended April 6th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited) were £3,113.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have decided to recommend the undermentioned dividends for the six months ended December 31st last:—On the First and Second Preference shares, 6s.; on the Ordinary shares, 9d.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 831.—Vol. XXXII. FRIDAY, APRIL 20, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The Northern Society of Electrical Engineers is to be congratulated on its Papers on underground mains, and more particularly on the discussion which followed them. We will make no comparisons: sufficient unto each Society is the science or the engineering thereof. It is, however, noteworthy that it is from Manchester and not from Westminster that we get the interesting news that the cost of maintenance of the bare-strip conductors in Kensington is only 0·43 per cent. per annum, and that in the City of London an average demand of 4½ 8-c.p. lamps per yard of frontage has been provided for. A good deal of further information on the City lighting was given. It is possible that an account of this mysterious system will first be given in Japanese at the Electrical Society at Tokio, and will be published with characteristic illustrations in the 電氣學會雜誌

We have been obliged, through pressure on our space, to omit the long mathematical reasoning—we cannot call it proof—of the (theoretically) best resistance for the receiver on a leaky telegraph line. Dr. Sumpner has sent us a very much shorter proof, based on Bosscha's corollary of Kirchoff's law. The problem seems to be nothing more than a case of Jacobi's law, and, like Jacobi's law, it is not a sound guide for practice. Jacobi's law states that the mechanical work given out by a motor is a maximum when the motor is geared to run at such a speed that the current is reduced to half the strength that it would have if the motor were stopped; under these circumstances only half the watts furnished by the external source are utilised, the other half being wasted. Another well-known case is that the external work done by a battery is a maximum when the external resistance is equal to the internal resistance. In the present case the telegraph receiver is the motor, and the line may be taken as part of the internal resistance of the battery. The law says that half the watts must be wasted. In the simple case, the volts are wasted, being lost on the resistance. All the amperes arrive safely, and, being multiplied by the surviving volts, present themselves as available watts. If, however, the line leaks, whether at one end, at the middle, or all along continuously, some of the amperes are lost (no matter what becomes of them) and hence the watts at the motor are reduced. The same law holds, for it applies only to the resulting watts, and takes no account of the proportion of the constituent volts and amperes. As every student knows, Jacobi's law is not one of maximum efficiency. Battery power, however, is cheap enough in telegraphy, and a little departure in the Jacobi direction from the condition of maximum efficiency is permissible. The usual desideratum is that the current should be enough to make the receiving instrument speak well, and if, as Prof. Hughes suggests, instruments are made by the hundred, with no thought of the resistance or leakage of the line on which they are to be used, a complicated coefficient for telegraphic apathy must be introduced.

The new shunt box recently described by Prof. Ayrton and Mr. Mather, has the two important advantages that, within certain limits of resistance, it is applicable to any galvanometer; and that, when used with a ballistic galvanometer, the multiplying power of the shunt is unaffected by the extent to which the swings of the ballistic galvanometer are damped. The accuracy of ordinary shunt boxes is dependent on the temperature of the galvanometer coils, a quantity which is difficult to determine with any exactness. This defect is removed in the new form of shunt, as the accuracy of the latter only depends on the ratio of the resistances of the shunt coils. While, however, these advantages are beyond dispute, the further claim made that the resistance of the circuit is less altered when the new shunt is used than when the ordinary form of shunt is employed cannot be maintained. As a matter of fact, the change is sometimes greater and sometimes less. The fallacy in the argument given by the authors occurs in the last two lines of the appendix to their Paper, and arises from assuming that the resistance of the shunted galvanometer is always diminished when the shunt ratio is decreased. With the ordinary form of shunt, the change in the resistance of the circuit must always be less than that of the galvanometer; while with the new form, if, as is recommended, the resistance of the shunt is large compared with that of the galvanometer, the increase of resistance by using the shunt may be many times that of the galvanometer.

The experiments accompanying the Paper are only conclusive in showing that a galvanometer with a serious amount of damping, and therefore badly suited for ballistic purposes if the ordinary form of shunt is to be used, can be employed with the new form of shunt for the accurate comparison of condenser discharges. The results given for the comparison of currents are so nearly alike for the two forms of shunt, that the minute difference observed can quite easily be attributed to slight want of proportionality between the deflections of the

Digitized by Google

galvanometer and the currents producing them. The selection of a shunt which happens to give a ratio of 99·63 for purposes of comparison was unfortunate, and greatly reduces the value of the experiments. The resuscitation of galvanometers with astatic needles and control magnets was hardly to be expected from Prof. Ayrton, who, we thought, had demonstrated the all-round superiority of suspended coil instruments.

The Paper read last week before the Institution of Electrical Engineers on the use of a hygroscopic varnish for the glass covers of voltmeter and other instruments was intended to be of a thoroughly practical character, and the idea will doubtless have its uses, especially in those climates in which you can light the gas by shuffling across the carpet and offering a knuckle to the gas-burner. When, however, the author of the Paper, instead of stroking the glass with his finger, rubbed it briskly, if not violently, with a handkerchief, the audience was convulsed with laughter. For three-quarters of an hour they had had an object lesson in the discomfort of naked glow lamps placed on a level with the eye, arranged, no doubt, to illuminate the dials, but incidentally facilitating the experiment by making the glass hot and dry. Just before the meeting, and not knowing which voltmeter had been varnished, we rather incredulously stroked the glasses of both instruments with a finger, as suggested in the Paper (which says nothing about rubbing with a dry handkerchief), and found no deflection in either case. In reply to an inquiry, we have received the following letter from an engineer of unusually wide experience:—

Manager's Office,
The —— Electric Supply Company (Limited),
London, W., April 17, 1894.

Dear Sir: I am obliged for your letter of yesterday's date, and am under the impression that Prof. Ayrton's varnish is to rectify a phenomenon rather than a common fault. Our instruments are now in a state of cleanliness which they have never before attained, for I have personally rubbed them until my arm ached, and have got my staff to do the same, but out of about 65 instruments I have only come across one which gives the amusement referred to, but this particular instrument does it so well that I must really tell you all about it.

It is a voltmeter with a scale up to 250 volts, continuous current, ordinary magnetic type, with a glass cover about 8in. diameter. I have this morning succeeded in obtaining a deflection 250 (volts ?) with the assistance of a tobacco pouch, this was simply stroked across the glass and quickly withdrawn. This rather shows there is a strong affinity between electrical pressure and tobacco. The instrument held the charge for a perceptible time, although it was in an ordinary engine-room in the usual African temperature, but the slightest moisture such as breathing on it dissipates the charge almost instantly, and then the instrument is none the worse, and all goes on merrily as before. But I find it very hard work breathing on the glass, for it requires a lot of puff, and requires some training for the art, such as one might obtain in a German band. I also find that rubbing the glass with a piece of paper gives far more pronounced results than an ordinary coat or cloth, &c. A piece of oily waste does nothing until the oil is polished away, but then, of course, the glass gets so much cleaner that this may possibly give rise to an impression that oil will not dissipate the charge. I cannot quite swallow the remarks about wiping the glass with the finger, or an accidental touch with the coat sleeve; I really have tried it, for my finger is sore, and I have almost worn a coat out with "accidental touching.' It really seems necessary to apply a certain amount of pressure and friction on the glass before an effect is produced, and it is quite clear that instruments are on the market and can be obtained, which will give rise to serious trouble if the men are too energetic in polishing up the instruments when they are reading them; but I have never known men to suffer much from this disease. As a practical source of annoyance I cannot believe it is so serious as Prof. Ayrton would have us suppose; even at the worst a strip of gold leaf inside a glass cover would obviate all trouble.

Of course, we must remember that other voltmeters will give trouble if treated in a particular manner—take, for instance, the Cardew voltmeter. One caused us to use bad language, for a greaser quite fresh to his work had been instructed to immediately cool any bearings, &c., which heated, and having, in his troubles, touched the Cardew voltmeter, and finding it hot he immediately swabbed it down with a bucket of cold water. Our customers said they had never had such a good light before, and very likely they never will again. I shall be pleased to show you the instrument I have mentioned any time you like to call here.

The working man is beginning to show signs of fighting against the employment of "mere electricians" in electric supply stations. This alleged flagrant violation of the principles of trades unionism has brought about a conflict between the Portsmouth Branch of the Amalgamated Society of Engineers and a set of men designated as "not mechanics but professional men," who are employed at the electric light station in order to "deal with no less than thirteen dials and work out mathematical calculations." The grievance of the unalloyed but amalgamated working engineers is that these "scientists" are receiving a *lower* rate of wage than the standard wage for mechanical engineers, and they are jealous that posts, which they consider could very well be filled by "the working man," should be held by men who do not enjoy the unalloyed happiness of being members of their amalgamated society, but who "the moment anything went wrong with the plant would be compelled to fly to mechanics for the execution of repairs." Further details of this incident will be found in our Trade Notes.

King's College Annual Dinner.—This will be held on Wednesday, May 30th, at the Holborn Restaurant. Sir Richard Webster will take the chair.

"James Forrest" Lecture.—There will be an extra meeting of the Institution of Civil Engineers on Thursday, May 3rd, at 8 p.m., when the second "James Forrest" lecture will be delivered by Dr. John Hopkinson, whose theme will be "The Relation of Mathematics to Engineering."

Electric Lighting Orders.—The Board of Trade has made Orders under the Electric Lighting Acts, relating to Barrow-in-Furness, Buxton, Chipping Wycombe, Chesterfield, St. Helens,' West Hartlepool, Grimsby, Harrow, Leyton, Monmouth, Peterborough, and St. Austell, and Bills to confirm them have been just laid before the House of Commons.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
Garachico-Santa Cruz de Palma	Dec. 27, 1893	April 7, 1894.
Bonny-Cameroons	Mar. 21, 1894	April 16, „
Fao-Bushire	Mar. 20, „	April 9, „
Cayenne Paramaribo	Oct. 25, 1893	—
Bissao-Bolama	Nov. 24, „	—
Brest-St. Pierre (P.Q. Co.)	Mar. 29, 1894	—

' Singapore-Labuan Cable was opened for traffic on the 14th inst.

The Antwerp Exhibition.—One of the features of interest in the Antwerp Exhibition will be a number of exhibits illustrating the history and progress of the various forms of artificial illumination. All kinds of lights, from the early Pompeian and Roman lamps down to the most modern forms of electric lamp, will be represented. To electrical engineers a complete series of exhibits of this character would be both an interesting and instructive sight, and it is to be hoped that every effort will be made to make it as complete as possible.

Royal Society.—The following Papers were down for reading before the Royal Society:—Prof. Hartley, F.R.S., "On Variations observed in the Spectra of Carbon Electrodes, and on the Influence of one substance on the Spectrum of another." E. H. Barton, "Electrical Interference Phenomena, somewhat analogous to Newton's Rings, but exhibited by Waves along Wires." Lord Rayleigh, Sec. R.S., "On an Anomaly encountered in Determination of the Density of Nitrogen Gas." G. F. Emery, "Thermoelectric Properties of Salt Solutions."

Electric Railways in London.—The Charing Cross and Hampstead deep level would, in the opinion of *The Statist*, be greatly improved if the line were to be extended across the river to Waterloo. "Then it would be possible to drop the parallel conception of the Waterloo to Baker-street line. Another hint. The extension of the City and South London railway is going to the Angel at Islington. There will be a terminus at that centre, and another of the Charing Cross and Hampstead line at Euston. Now, about half-a-mile of underground extension between these two terminals under the Pentonville-road, would give a splendid sweep of railway at very small cost, because there are no terminals to build. We could then run from Euston to Stockwell."

Waste Steam and the London Sewers.—In the London County Council's General Powers Bill now before Parliament a penalty not exceeding £20, with £5 a day for continuance, is imposed for discharging into the sewers "any waste steam, condensing water, heated water or other liquid (such water or other liquid being of a higher temperature than 110 degrees Fahrenheit), which either alone or in combination with other matter or liquid in a sewer may cause a nuisance or involve danger or risk of injury to the health of persons entering the sewers or be injurious to the structure or materials of the sewers or works of the Council." Any penalty under this section is only to be recoverable by the Council, and no proceeding under this section to recover any such penalty is to be commenced except in pursuance of a recommendation from the Committee of the Council charged with the management of the sewers after a report from the medical officer, chemist, or engineer of the Council.

Obituary.—Col. William Haywood, the engineer to the City Commission of Sewers, died on Friday last. He had occupied this post for 48 years. The construction of the Holborn Viaduct was carried out at a cost of nearly four millions under his direction, and among the many other important street improvements may be mentioned the construction of Queen Victoria-street. Col. Haywood took a very early interest in the introduction of the electric light to illuminate the streets of the City. He visited Paris with a Committee of the City Commission of Sewers in 1878, and again in 1881 in connection with the question. Under his supervision the sum of £12,000 was expended in experiment and trial by the Commission. His reports on the subject were numerous and exhaustive; but he had a strong aversion to the City authorities themselves undertaking to generate and supply the electric energy. He gave close attention to many of the details of the present system of street lighting in the City.

Capt. Abney on Photometry.—In his concluding lecture, Capt. Abney described the use of revolving sectors for reducing a beam of light. Fox-Talbot was the first to employ this device, and Mr. Kempe was the first to introduce a mechanism for altering the size of the opening while the sectors were in motion. He had used this system for 10 years and had never know it fail. He alluded to the work of an American experimenter who thought that an error was introduced when small openings were used. It was admitted by this experimenter that with monochromatic light there was no error; it followed that what was true for each ray was true for the sum of them. He would not waste the time of the audience over such fallacies. Various uses and modifications of the Rumford or shadow photometer were shown, as, for example, the measurement of the reflecting power of opaque screens, in terms of the reflecting power of white paper as a standard. The method of calibration of an absorption wedge, both for white light and for the spectrum by the use of a split beam was explained. The author concluded by showing the greater extinction of red than of green light when the luminosity was reduced. A screen illuminated by red light equal to the candle-power of an amyl-acetate lamp ceased to be visible at50ft., but an illumination by green light of the same candle-power ceased to be visible at 700ft.

Electric Cooking.—Homer sometimes nods, and the usually well-informed *Pall Mall Gazette* recently published an article extolling the electric cooking at the Chicago Exhibition, and making no reference whatever to the state of this art in England. Amends were, however, made on Monday last by a full description of Messrs. Crompton and Co.'s system. An oven, heated to 350°F., taking 25 amperes, is heated in a quarter of an hour with rather more than half a Board of Trade unit, and as there is no draught through the interior, as in a gas oven, it will retain its heat for an hour, and if more is required, a very small current will suffice. A frying pan takes 2½ amperes, and to boil water on a small scale for tea costs one-sixth of a penny. In the course of an interview, Mr. Crompton is reported to have said:—

The Americans are generally supposed to have invented this notion, and we to have stolen it; but, as a matter of fact, we are miles ahead of anything they have got in America, and I fairly startled an American who came to see our things fresh from the Chicago Exhibition. He refused at first to believe his eyes. The most important discoveries we have had to make relate to the enamels in which the wires are bedded, and to certain dry processes of manufacture. It was thought to be impossible for a long time to get an enamel that would resist the very high temperatures required without softening. We have found one at last, and now we use three kinds of enamel. First of all a coating of the hardest enamel is laid on the iron plate, and the little conducting wire is spread upon it. Then a second coat of enamel, not quite so hard, is laid over that; and finally, a coat of decent white enamel is spread over all. The difficulty used to be to put on the second layer without melting the first, and allowing the conductor to sink through and touch the iron plate. Another important change we have made is the substitution of nickel-steel wire for copper or some other metal, which was used at first. But the thing which has really settled the business, and made the industry a practicable one, is a method we have devised for crimping and laying on the fine wire by machinery on to a dummy plate, and so transferring it bodily to the enamel. Formerly it used to be laid on by hand, a difficult matter at the best, and most trying when you are dealing with hot layers of liquid enamel.

The New Atlantic Cables.—The cable-ship "Faraday," belonging to Messrs. Siemens Brothers and Co., has just left the Thames with the first portion of the Commercial Cable Company's new cable aboard. There are at present working ten Atlantic cables, and two more will be laid this year. Of these twelve cables, seven will have been made and laid by Messrs. Siemens. In 1875 Messrs. Siemens laid the Direct United States cable, in 1879 the French cable, in 1881 the northern Western Union cable, in 1882 the southern Western Union cable, and in 1884 two cables for the Commercial Cable Company. The following are the weights of material used in the manufacture of the third Commercial cable, which is in all 2,201 nautical miles in length:—Copper wire, 495 tons; gutta-percha, 315 tons; jute yarn, 575 tons; steel wire, 3,000 tons; compound and tar, 1,075 tons; total, 5,460 tons. The laying will be done in two expeditions; the first, which has just started, will comprise the shore ends and intermediate sections—in all about 700 nautical miles. The first section will be laid from Waterville, in Ireland, out into deep water, and the end will then be buoyed. The second section will be laid from Canso, in Nova Scotia, over the Great Bank of Newfoundland into deep water, and this end will then be similarly buoyed. The "Faraday" will then return to Woolwich to take in the cable for the second expedition, which will start in the middle of June, and will comprise the 1,500 nautical miles of deep-sea cable.——The new cable for the Anglo-American Company, to be laid from Valencia to Heart's Content is being manufactured by the Telegraph Construction and Maintenance Company, and it will be submerged during the summer; two of the latter Company's ships being employed in the operation. This cable, some 1,850 knots in length, will be mechanically and electrically probably the most perfect cable yet manufactured. The conductor will contain more copper to the mile than that of any submarine line yet made, which will give a very high speed of transmission—over 40 words per minute. The 1873 Atlantic cable has never required any repair to the deep sea portion since is was laid 21 years ago, and there cannot be any doubt that cables recently constructed, with all the knowledge acquired by the experience of the past, should have a much longer life and greater immunity from interruptions than in the case of those laid in the earlier years of submarine telegraphy. Of the fifteen cables (including the three earliest, not now working) which have been laid or are about to be laid between Europe and North America, eight will have been made and laid by the Telegraph Construction Company, viz, those of 1858, 1865, 1866, 1869, 1873, 1874, 1880, and 1894.

THE TESTING OF ENGINES AND BOILERS.*

BY PROF. ALEX. B. W. KENNEDY, F.R.S.

LECTURE II.—ENGINE TESTING.

The lecturer said that he would in this lecture confine himself entirely to engine testing, and in order that he might keep himself within reasonable limits, he would practically confine what he had to say to the testing of steam engines of a stationary type; he should not speak of locomotive or marine engines, nor of gas engines.

In engine testing they were looking for two quantities essentially, first the consumption of water per horse-power hour, and secondly the ratio of net to gross power, or what was commonly called the mechanical efficiency of the engine.

He would take the question of water measurement first. Water might be measured for engine trials in two ways, either into the boiler or out of the engine. As to methods of measuring into the boiler, he had practically nothing to add to what he had already said in his previous lecture. He would only give them one caution, which did not affect the question of boiler testing but did affect engine testing. Sometimes, where they had a very big boiler and a very small engine, they were tempted to measure the steam used by the engine by getting the water high in the glass to start with, evaporating it until it stood low in the glass, and then measuring it by pumping in enough water to fill up the glass to its original level. This should never be done. The errors caused by change in the mean temperature of the water in the boiler and by the vagaries of the gauge might be 20 or 25 per cent. of the quantity evaporated.

By measuring the water that was used *out of* the engine was meant, of course, measuring the steam after it was condensed. That could be done easily and readily by any of the methods of water measurement which he had mentioned to them, if only they had a surface condenser to work with. If they had not a surface condenser, it was obviously out of the question, although of course possible by certain calculations. But it was obviously an undesirable thing to calculate any quantities which were capable of being directly measured. So for practical purposes they either measured the water as it went into the boiler, or, in the case of a surface condensing engine, they measured it when it came out of the engine. He need hardly say that there were many advantages in the latter plan if only they could carry it out practically, because the water that went into the boiler did not all get to the engine *as steam*. Not only might there be priming in the boiler, but also a good deal of steam actually formed might sometimes be condensed in the steam pipes and get to the engine finally only as water. Therefore, to find out the amount of actual steam which got to the engine as steam it was well to use a separator just before the engine in the hope that the separator would catch all the water in the steam before it got to the engine, and so allow it to be measured separately. He need hardly say that they had not yet, unfortunately, got a convenient form of portable surface condenser, so that nearly all engine tests which they might have to carry out would have to be made by measuring the water into the boiler. In that case they had to be doubly particular about correction for height of water level, and the thing to aim at was to make that correction as small as possible by keeping the level as nearly as possible constant during the whole running of the test.

As to the duration of an engine trial, this need not be so long as the boiler trial if only they could get the conditions steady. They could not get the conditions of combustion in a furnace steady under a very considerable length of time, as he had pointed out before. But if they were measuring the water out of the engine; if, for instance, they were letting it run into a large tank on a weighing machine, so that they could tell exactly how long each 100lb. took to pass through the engine into the tank, it was occasionally possible with steady working to get a good trial even in half an hour, quite easily in an hour. Suppose, for instance, that they found that the time intervals per 100lb. of water were consecutively 1min. 52sec, 1.53, 1.50, 1.52, and so on. If this went on for half an hour they might safely consider they had got into steady condition, and in such a case half an hour might be sufficient to give them a trustworthy figure—one which would continue the same if the trial continued for ten hours. They could not, however, do that if they were measuring the water into the boiler. In that case the trials must be much longer; it was generally a matter of several hours even as a minimum in the case of an engine trial.

Incidentally, between the water and the power measurement, they required to know the steam pressure, rather because it was an important piece of information, along with the steam temperature, than because it was actually much used in engine-trial calculations. The steam pressure would be read by means of a steam gauge; and of all the lying pieces of apparatus for which engineers were responsible perhaps steam gauges were the least trustworthy. The best thing to do, no doubt, if they wished to gauge the pressure fairly accurately, was to put a steam engine indicator with a tested spring on to the boiler beside the pressure gauge and calibrate the pressure gauge by the indicator.

Now as to power measurement. Here three quantities were required: (*a*) the engine dimensions; (*b*) the mean piston pressures; and (*c*) the speed. It was no use getting the mean pressure right to seven places of decimals if they made a mistake of one revolution per minute, which would often correspond to an error of 1 per cent.—each of the three quantities required to be found with the same degree of accuracy.

As to the engine dimensions he might just remind them that if they were testing an engine about which they did not know anything, and if something depended on the result, it was advisable to have off the covers and guage the real dimensions for themselves. They would also not forget to make an allowance for the rods in the cylinders.

Assuming that they had got the engine dimensions right the two other matters were those to which they would pay most attention. Let them take the pressure first; that was to say, the thing which they measured by the use of a steam-engine indicator, because, as they knew, no engineer or inventor had been kind enough to bring out for them a power measurer which would really integrate the work done by the engine. From the indicator diagram they really measured only the mean height, or pressure, and not the area or work. It would be a very great benefit to all who had to do with the running of any kind of engines if they could find out at any instant the rate at which work was being done. Such pieces of apparatus existed in books, and he believed they had been made. He was afraid it would puzzle them very much to buy one. They must therefore content themselves with using an indicator as a method of measuring pressures. Of course, in measuring pressure they depended on two things—first, the mechanical accuracy of the indicator, the size of its cylinder, the ratio of its leverage, and so forth, which could be reasonably well tested; and secondly, the accuracy of the indicator spring.

Since the Crosby type of springs had been introduced, much more reliance could be placed on indicators than was formerly possible. Probably few of them could in their ordinary work really test indicator springs, but it was always possible to get them tested against a mercury column, and it was very advisable to have this done from time to time. Time would not allow him to discuss different types of indicators. He supposed most of them who had to do with high-speed engines at any rate used Crosby indicators. There were other indicators for high-speeds in the market, but they were newer and not so well-known. There were, of course, also the older types of indicator, now very much improved in construction, which were perfectly useful and reasonably accurate for all speeds up to say 80 or perhaps 100 revolutions per minute. Indicator gear, the apparatus for driving the indicators, formed a subject about which a good deal had been written.

It was a very useful exercise, which he believed he had more than once set to his old students at University College, to find out the possible error in an indicator card caused by a peculiarly bad arrangement of indicator gear. His recollection of the matter was that they had to arrange their indicator gear uncommonly stupidly in order to produce any sensible error in the diagrams! He thought, therefore, the

* Two lectures delivered at the Finsbury Technical College, Dec., 1893.

Digitized by Google

question of indicator gear might on the whole be left to the common sense of the engineer in charge of the test. Some of his own assistants, he thought, would say that it was a much greater difficulty that the indicator gear was sometimes so made that if anything went wrong to it they had to stop the engine to put it right. This also is mere matter of common sense. There were two or three things they required specially to note. The use of strings that were longer than was absolutely necessary was to be avoided ; the use of steam pipes to their indicators which were longer than was absolutely necessary was to be much more avoided ; and when those pipes were comparatively small in area they had to be avoided altogether. He was not prepared to say that with a slow-running engine they might not get very fair results—probably correct results—from an indicator placed on the ordinary double mounting connected to each end of the cylinder by one pipe with a three-way cock below the indicator ; but it was not an advisable arrangement to use, and was very liable to cause considerable error unless the pipes were of very ample dimensions indeed ; he meant unless they were ¾in. bore, or something like that. But the arrangement should certainly not be used if the engine were a high-speed one. In that case they should make the pipes perfectly straight, put the indicator right on the end of them, and keep everything as short as they possibly could. He might, perhaps, give them one or two practical hints about the indicator cards, as to what they should put on them and what they should do with them. The best rule on the whole was to put as little on the actual indicator card as possible. He was supposing now that they were carrying out a trial in which they might have to take from 20 to 30 sets of indicator cards, each set, perhaps, having four or more diagrams. The main thing to have on each card was a number and a date. One indicator card was very like another, and after they had been lying in an office for months the only way of identifying them was by the date, which should be marked by a date stamp. What they really required for their indicator cards was a log-sheet, which should have something like this information on it : in the first column "Time," in the second the number of the diagram, in the third the revolutions per minute, and in the fourth possibly the steam pressure at the engine. It really was of no use writing a lot of statistical information on the back of their indicator cards when they were carrying out a test. It was very nice if they had one set to show everybody, but for serious testing it was only a nuisance.

He had with him a little set of rules which he made out in connection with some very important trials which he was carrying out a little while ago, and he added them here in case they might be of use to his hearers.

Instructions for taking Indicator Diagrams.

See that indicators have the proper length of stroke and are not on their stops.

Blow through before taking every card.

Mark number of card in top right-hand corner.

Let H.P. top cards begin with No. 1, H.P. bottom with 101, I.P. top with 201, I.P. bottom with 301, L.P. top with 401, and L.P. bottom with 501.

Let top and bottom cards of each cylinder be taken as nearly as possible together, and the whole set as quickly as possible.

After having taken a set of cards and entered time in log, &c., put on the new papers at once for the next set.

Draw atmospheric line by hand with full stroke of indicators.

In cases where the work is divided into watches, proceed as follows :—

First watch to get indicators ready before starting, and note numbers of indicators and marks and scales of springs on log sheet.

Second watch to verify these numbers and after taking last cards on the watch interchange top and bottom indicators of each cylinder.

Third watch to verify the changed numbers.

Fourth watch, after taking last set of cards, to take off indicators, verify the springs, and put them in boxes.

Examine every set of cards before putting away, to detect anomalies or errors. Compare top and bottom cards of each cylinder for length, pressure and general appearance. If any difference is noticed, or anything suspicious about cards, report at once to engineer in charge of the test.

Keep the indicator boxes shut, and the papers in them.

Most of these points would be well-known to any of them who had been taking indicator cards largely, but certain points might possibly be novel.

It was a very good plan in the middle of a trial, especially if the cards had been at all queer, to change the indicators from top to bottom, and *vice versa*; they might sometimes find out then that the fault had been due to the indicator, or make certain that it had been due to a valve set. One other thing. While the cards were being taken, keep an eye on them. He meant, do not take them as a matter of course and finally put them away and go on to another set, but examine them carefully and see if there is anything suspicious about them. By doing that they could "spot" an error and be able to say whether it was an error in the indicator or in the engine. When taking the cards let the pencil go over each a dozen times or more. They should not upon any account entertain the horrible idea which some people did, that it was nice to have but one line ; it might make a pretty card, a cleaner line, and so on, but that was not what they were seeking—that was obviously a matter of no importance.

Supposing they had got their cards, the next thing was to get a result from them ; that was to say, to measure the mean pressure. Suppose their indicator springs were checked, or that they knew that they were right, that they had got their diagram, and that they now wished to get the one result for which they took that diagram. He was surprised to find a little while ago that diagrams were still being calculated by the laborious process of dividing them into ten parts, then measuring and writing down separately the pressure at each tenth—even putting it sometimes separately above and below the atmospheric line—then adding together and dividing by ten. He hardly imagined that any student of the Finsbury College would use—or perhaps even know of—this method! He need not say there was no occasion for it at all, unless they wished to give the largest possible chances of error. Probably the best way of measuring indicator cards was by means of a planimeter. He thought, on the whole, a planimeter, carefully used, and taken round every card twice, would be more likely to give correct results than any measurements of ordinates. But planimeters were not always at hand. When without a planimeter the best plan was one of which Mr. Maw, the editor of *Engineering*, had told him long ago ; he did not know whether it was original with him, or from whom it came. It was simply this : divide off the card into the usual ten parts, draw the lines if their eyes were not sufficiently accurate to guide them square across the atmospheric line, then take a long strip of paper, at least ten times as long as the height of the card—sectional paper of the length of foolscap would do—mark the height of the first division upon it, then move the strip until they got to the next division, mark that, and move on to the next, and so on. Then the marked length on that piece of paper was the sum of the lengths of the ten divisions, and the only error they could have made would be the error of parallax in marking the paper when they put it right on to the indicator diagram, which was a very small error. They did not have any arithmetical error in adding up their ordinates, because they had not measured them separately, they simply measured with the ordinary scale of inches divided into tenths, or whatever it might be, and simply marked off the decimal place. On the whole, he thought that was the quickest and most accurate method of getting the mean pressure from an indicator card if they had not a planimeter. If they had a planimeter they should use it. Those who did use them most could generally put them up to a few little dodges for reading them without absolutely destroying their eyesight before they grew old! When they had got their mean pressure they wanted to calculate from it the indicated horse-power. (They would suppose for a moment that they had got their speed.) There were one or two matters connected with the calculation of power from cards which were worth remembering. If they had a great number of cards in one trial all taken at about the same power it was obviously unnecessary

Digitized by Google

for them to calculate the power of them all. They would calculate the mean pressures for them all and then find the mean mean pressure and get the power from it. That would save them a good deal of arithmetic. In any case, of course, they would use an "engine constant." That was to say, they would not go through the formality of multiplying by the area and dividing by 33,000, or whatever it might be; they would use an engine constant which was really the power the engine would give out with 10lb. mean pressure and 100 revolutions per minute, or something of that kind. That engine constant included all the arithmetic except the speed and the mean pressure, and as those were variable they could not, of course, include them in any constant. They would find it extremely convenient, if the engine were a compound one, to reduce the mean pressure to the low-pressure cylinder and to work finally with only the pressure reduced to the low-pressure cylinder. Until they had used that method of working they would hardly know how convenient it was, and what an insight it gave into the extent to which engines were fully loaded. They knew, for instance, that an engine working with 150lb. boiler pressure might have a mean pressure reduced to its low-pressure of 45lb., 50lb., or 55lb., depending on the ratio of expansion, and so forth. If in such an engine they found the mean pressure reduced to the low pressure cylinder was only 25lb., they at once had an important piece of information, that that engine was working with such a high ratio of expansion that it was only doing about half the power it was capable of doing. He did not say that it ought to do double the power, but they knew it was only doing half, and that was a piece of information which it was often rather important to have. The only way of getting it clearly in their minds was to have all their pressures reduced to the equivalent pressure on the low-pressure cylinder.

He would now go on to the consideration of the measurement of the speed of the engine, that was the number of revolutions per minute. This was done in three ways. It might be done by a counter or by a tachometer, or simply by the use of a watch. The counter might be of two kinds. For most engines, at any rate for those which did not run too fast, it was better to have a regular Harding counter, an integrating counter, one that told the total number of revolutions made from the beginning. That was the ordinary form of counter with a dial more or less like a gasmeter dial, one which carried automatically. Assuming the counter to be working right, it would give absolutely the number of revolutions made during the trial in a way that nothing else did. It did not give the number of revolutions made at the particular instant when they were making diagrams; but if they had a long trial and many diagrams that did not matter. There was another good counter, called the Eddy counter, a very ingenious thing, which had a piece of clockwork inside it. It ran for half a minute, and was driven by the engine itself when pressed against the end of the shaft. They had only to set the counter to zero, put it against the shaft and let it run. The number of revolutions could be read off from a dial. He had tested this counter, and it certainly was convenient. It, however, had the drawback that they could not check it. They could only check it by comparing it with a stop-watch, and comparing two half-minutes on the stop-watch and another on the counter was not easy. There was a very nice counter recently brought out, called May's counter, a counter with a dial something like a watch face, which they merely pushed up against the engine shaft in the usual way, allowing it to run for a certain time by the watch. The only particular point about this was that it ran either way and recorded either way rightly, having a very pretty reversing apparatus inside. Or they could take another of the common forms of counter. As, for instance, the very good Harding counter of the same type, which could be pushed up against the end of the shaft. There were two things they needed particularly to notice. One was that the end did not shift on the shaft. It was very liable to do so if the holes were not good; that was to say, if the pin on the end of the counter did not bite the punch mark on the centre of the shaft. They could feel if it slipped, but of course could not make the correction. They could sometimes get over that by using india-rubber on the end of the counter pin, or anything to make it stick. The second point was a much more important one. Any counter, except Eddy's, was dependent on the time for its correctness. For that there was nothing like the ordinary stop-watch, one that could be started by the pressure of the finger in the usual way, because there was no difficulty in holding the counter and the watch close together, or in making the two actions simultaneously. They could easily withdraw the counter at the instant the large hand of the stop-watch got round to its minute or half-minute. He strongly advised them to make it a minute; errors were not always easy to avoid with half a minute, especially if they were not quite accustomed to doing that kind of thing, and especially if they had not a watch with a centre-seconds hand that went right round the dial. It was not at all easy to get an accurate reading for a minute, still less for half a minute, on the seconds hand of an ordinary watch.

Then they could get the readings by the tachometer, which registered automatically the speed per minute. It had a pointer whose indications were proportional to the speed, and from which they could read off from the dial the exact speed. This was mainly of importance as telling them whether or not their engine was running steadily. They must never trust to its indications until they had actually checked them by a positive counter of some kind. After they had checked a given tachometer with a positive counter, and found it right, they could, of course, trust it, or at least for a certain time. Or, lastly, they could get the revolutions in the ordinary way by counting either by ear, or by letting some part touch the hand. But in this case they should never forget that it was necessary always to begin counting with "nought," and not with "one," otherwise they would have one revolution too many.

He would emphasise that it was no good taking special pains, getting their indicator springs checked and using the very best instruments they could get, and taking all sorts of elaborate precautions if they counted the speed for half a minute in a careless sort of manner, for an error in the speed had just the same effect as an error on the indicator card.

The next thing, and a very important one, was, the resistance on which the engine was to be worked, especially if they wished to find its mechanical efficiency. Of course, if the engine were working a factory, or anything of that kind, they were simply getting the gross indicated horse-power, and that was all they could measure; but if the engine were being tested for mechanical efficiency, they wished to find something for it to work on, and they must find some kind of resistance, generally in the way of a friction brake. Engineers had been working for many years at a transmission break, an instrument which should transmit power and measure it while it transmitted it. There was not very long ago a very neat transmission brake in that building of Prof. Perry's, but he did not think that it had been made on a large scale. There was in point of fact no transmission brake made on any very large scale. Therefore they had to use an absorption brake, which actually took up the work that was being done. The most convenient brake for them to use under all circumstances was, no doubt, a rope brake, such as he believed was first used by one of Messrs. Ransome's foremen for a rough trial conducted somewhere in Egypt, and described by Sir Fredk. Bramwell many years ago. There was a flywheel to the engine, or a pulley put on specially for the purpose. Around that pulley was carried a rope, or two, or three, or four ropes, a weight was attached at one end, and a spring balance fixed at the other. The actual weight on the brake was, of course, the difference between the value of the weight and the readings on the spring balance. Both these could be accurately measured, and the radius to the centre of the rope. When those measurements were made, the speed and the brake power could be measured quite accurately, independently of co-efficients of friction, or of balancing or adjusting levers, or anything of the sort. A brake such as that he exhibited could be made very easily indeed. That brake was used at the Society of Arts' trials a good many years ago, and the whole thing was worth only a few shillings. It was a very cheap instrument for an instrument of such extreme accuracy. This particular brake at the Society of

Arts' trials carried about 15-brake horse-power; it consisted of two ropes of ⅝in. in diameter. It ran on a flywheel of 5ft. 6in. diameter at 160 revolutions, and carried a net weight of 177lb. The wheel was not cooled artificially or lubricated in any way, and that was the very outside weight they could have got out of it without overheating, so they might take that as rather a limiting case. In another case, where he was able to cool the flywheel with water, he had a flywheel 5ft. 9in. in diameter running at 137 revolutions, and he got a net weight of about 300lb. on it, and took up a brake horse-power of 19 instead of 15, with exactly the same brake, the difference being that in that case the flywheel was cooled. The largest brake that he had used, and he should fancy the largest rope brake that had been used, at least in this country, was on a flywheel 16ft. in diameter, running at 75·8 revolutions per minute. If they worked that out, he thought they would find about 44 miles an hour to be the speed of the fly-wheel rim. The net weight on the brake was about 300lb., and it took up 91 B.H.P., with four ropes in parallel each 1in. diameter. With those proportions they might be quite comfortable about the brake. The only thing was they had to keep it cool. In that case the fly-wheel was especially good, its rim was made trough-shape, and all that was necessary was to arrange a cock, always letting a little water run into it. The water was evaporated, and all that was necessary was to keep enough water in to prevent the wheel from ever becoming dry inside. He had had many trials with that brake, and never found the slightest trouble with it.

When they had got their indicated horse-power and their brake horse-power they had the efficiency of the engine at one power only. That might be sufficient for their purposes; it depended upon their object in making the trial. It certainly was not sufficient if their object was to know as much as possible about the engine. If they wanted to know fully how the engine was running they must make tests of it at different powers. They must measure, for instance, the brake horse-power, the indicated horse-power, and the total water consumption per hour at quarter load, half load, three-quarter load and full load. If this were done with care and completeness it would enable them to make such a diagram of mechanical efficiency and of water consumption at different loads as would practically tell them all the leading characteristics of the engine. For the best method of drawing such diagrams and the methods of dealing with them he could only now refer them to Mr. Willans' two Papers read before the Institution of Civil Engineers and the discussions on these Papers. If circumstances did not allow them to make the progressive trials really complete, it was worth while to get at least the consumption at half load as well as at full load. A diagram drawn from two sets of power measurements only was, of course, not a complete one; but it would certainly give them very much more than double the information that they would get from one set of power measurements only. At each load at least three complete sets of indicator diagrams should be taken. He had not specially mentioned above the taking of diagrams at no load—that is, with the engine running empty, because, although the results if accurate, were very valuable, the taking of these diagrams correctly was a difficult thing to do, and the power taken up by the engine running light was probably obtained more accurately from the curve than by direct measurement. The reasons of this would be familiar to any who had tried to take light cards. They were, first, that such cards were very apt to have loops in them, and the presence of such loops exaggerated very much all the errors caused by the springs. In addition to this, it was very difficult to keep the speed accurately steady at light loads, and any increase or decrease of the speed just at the instant while the cards were being taken would out of all proportion increase or decrease their area. It should be remembered, however, that for the taking of light cards it was not important that the engine should be run up to full speed. It should only be run at such a speed as would ensure that the cards would be quite steady. From these the value of the pressure reduced to the low-pressure cylinder could be obtained, and from it the indicated horse-power at any speed.

He was sensible that in the time at his disposal, although he had already exceeded the usual limit, it was quite impossible to cover the whole ground of such a large subject as that on which he had been speaking. He hoped only that he had been able to put before them a few of the more important points connected with it with which his personal experience had chanced to make him familiar.

THE ROLLASON WIND MOTOR.

We give this week an illustration of a small windmill plant for electric lighting by wind power, which is now to be seen in a field near Willesden Junction. The motor is designed to develop a maximum of 5 H.P. with an estimated wind velocity of 18 miles an hour; at very much higher winds than this, it being found advisable to switch the motor off the dynamo rather than to utilise the power it might develop. At the particular locality in which the mill is now placed, an average

The Rollason Wind Motor.

wind of from eight to 10 miles per hour can, it is said, be relied on for 10 hours a day. The wind motor is mounted on a light wrought-iron structure, and consists of four vanes measuring, over all, 19ft. by 20ft. These vanes are set at right angles to one another around a central vertical shaft, and each vane has the shape of a circular cylindrical segment. The driving force of the wind is directed upon the concave sides of the vanes; and, to eliminate back pressure on the convex sides, as they beat up towards the wind, these are protected by a screen. This screen is seen in the illustration, to the right of the central spindle. The position of this screen is automatically shifted when the direction of the wind shifts, so as to expose a maximum of vane surface on the driving side in winds from every quarter. The normal speed of the vertical shaft is seven revolutions per minute; and, at this rate, the dynamo which it drives makes 500 revolutions. The electrical power developed can either be stored directly in secondary batteries, or run

on to the lamp circuit with these batteries in parallel as pressure regulators. The electrical plant at Willesden Junction comprises 27 E.P.S. cells of the T type, each cell containing 15 plates; together with a number of complicated devices for preventing the light from fluctuating with the vagaries of the wind, as well as for throwing the wind motor out of gear when the wind is either too high or too low. We understand that the price of the motor is £200, exclusive of the electrical plant and fittings, or about £40 per maximum horse-power developed. From the meteorological records, the promoters of this wind motor estimate a mean of about 3 H.P., which would bring the cost per horse-power developed up to about £67; but we should be disposed to consider an all-round average of 2 or 2½ H.P. as being more nearly what might generally be expected, to say nothing of the losses which must take place between the motor and the lamp mains. It will not, therefore, be very wide of the mark to estimate the cost of motor plant alone at not less than from £80 to £120 per average useful horse-power. The electrical plant would, owing to its greater complexity, be more costly than usual, and might very well be estimated at not less than £120 per average useful horse-power, bringing the total prime cost up to more than £200 per horse-power. Now, a good gas engine of small power can be obtained for about £24 to £30 per horse-power, and the cost of electrical plant driven by such is not much greater; while a far less cost of up-keep and repairs might be expected, than in the windmill plant with its complicated system of storage of power. One further point: we do not see how it would be possible to build a very much larger motor than the sample one at Willesden Junction, so that anyone who needs more than about 3 H.P. would be under the necessity of erecting two—perhaps a whole row—of these engines.

AN ASTATIC STATION VOLTMETER.*

BY PROF. W. E. AYRTON, F.R.S., AND T. MATHER.

The rapid development of electric lighting generating stations during the past three years has resulted in a greatly increased perfection in the regulation of the pressure, and consequently has created a need for measuring instruments of much greater precision than was previously required. At the same time, the powerful dynamos now employed, and the large currents that flow through the mains on the switchboards at these generating stations, has greatly increased the disturbing influences to which electro-magnetic measuring instruments are subjected. Consequently, it is not to be wondered at that voltmeters and ammeters which answered fairly when the output of the stations was small have had to be discarded as being unsuitable for the present requirements.

The authors have, therefore, been engaged for some time past in developing an electro-magnetic voltmeter to fulfil the following conditions:—

1. Be unaffected by an outside magnetic field, whether uniform or not, and as strong as the disturbing magnetic field on any ordinary central station switchboard.

2. Be unaffected by an outside electrostatic disturbance such as is produced on rubbing the glass front of the instrument.

3. Have no temperature error.

4. Have a high resistance, so as to measure equally accurately the *true* pressure at the end of long thin pilot wires, or in the station itself.

5. Have a scale of large radius, and one very open at the working pressure, so that a small change in the pressure can be detected.

6. Be dead beat.

Condition No. 1 is most easily fulfilled by employing a powerful stationary permanent magnet and a moving coil, for such an arrangement has the great advantage that it cannot indicate a pressure unless a current be actually flowing through the coil; whereas soft iron and other types of voltmeters, when placed in a fairly strong magnetic field, may have the pointer deflected across the scale when no current whatever is passing through the instrument. But it is not sufficient to merely employ one permanent magnet and one moving coil, as is proved by the fact, which is probably not generally known, that the very beautiful Weston voltmeter,* in spite of the permanent magnet being strong, and the air gaps in which the coil moves being extremely small, indicates slightly differently when put in different positions in a magnetic field, even as weak as that of the earth's, the change in the reading being about one-fifth per cent. when the instrument is placed horizontally and turned through an angle of 180deg. in a horizontal plane. This voltmeter, therefore, cannot, of course, give constant indications in a varying magnetic field 50 or 100 times as strong as that of the earth's. Now, Messrs. Clark and Malpas have found, by experimenting with our portable magnetic field tester, that a field of 20 C.G.S. units, or one rather more than 100 times as large as that due to the earth, is the sort of magnetic disturbance that occasionally occurs on the switchboards of existing central stations, while fields of six C.G.S. units—that is, 30 times the earth's field—are quite common.

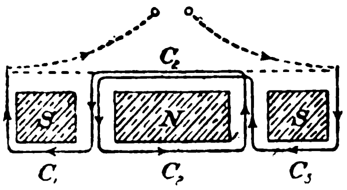

FIG. 1.

If the coil be wound astatically, and be acted on by two powerful permanent magnets inside the voltmeter, with their poles oppositely directed, good screening can be obtained from a uniform disturbing magnetic field; but errors will be produced if the disturbing field be *non*-uniform, such as is caused by a mass of iron, or by a conductor carrying a current, placed near the voltmeter. We have, therefore, carried this principle of astaticism further by employing *three* permanent magnets and a coil wound in three parts, as shown diagrammatically in Fig. 1, the area of the middle coil being double that of either of the end ones; and in this way we have obtained an arrangement which is comparatively unaffected by either a uniform or a non-uniform magnetic disturbance.

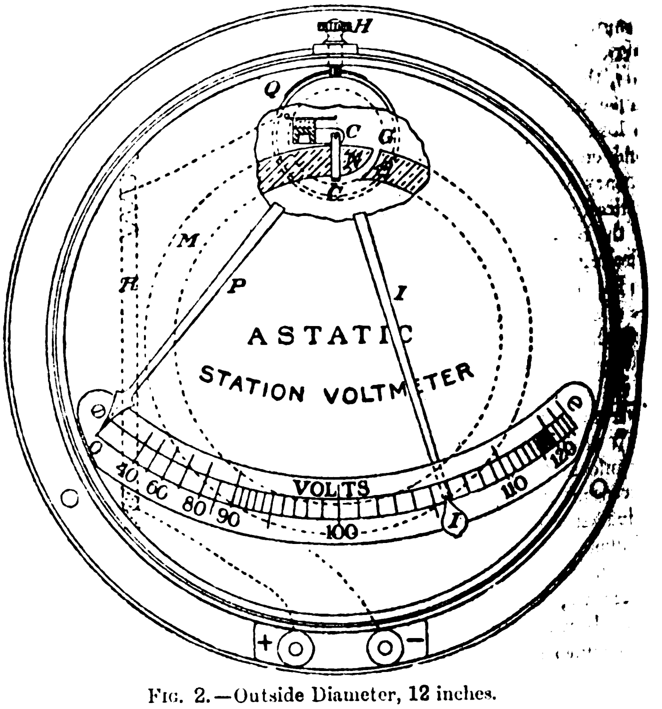

FIG. 2.—Outside Diameter, 12 inches.

The moving coil principle also enables conditions 3 and 4 to be fulfilled, for the resistance of this 100-volt instrument is about 7,000 ohms; and as only 3 per cent. of this is composed of copper wire —viz., that wound on the moving triple coil—while 97 per cent. is of manganin wire, indicated by the stationary coil R in Figs. 2

* Paper read before the Institution of Electrical Engineers, April 12th.

* Tests made from month to month of the sensibility of two of the latest form of the Weston voltmeter show also that the sensibility slowly *increases*. This arises, probably, from the permanent magnets having been too much weakened before these instruments were originally calibrated, so that the magnets have *increased* their strength with time. These two instruments now read 1·3 per cent. and 1·7 per cent. too high respectively, after allowing for the fact that the unit potential difference employed in the original calibration was the legal volt, and not the "Board of Trade" or "International" volt.

Digitized by Google

and 3, the temperature error is practically negligible. This high resistance also causes the power required to actuate the voltmeter to be very small, not more than about $1\frac{1}{2}$ watts being absorbed at 100 volts with this voltmeter.

The control is produced by a weight, because this is the method of exercising a controlling force that is least likely to vary, and because the objection to the employment of a gravity control—that the voltmeter cannot be used in any position—is of no importance in the case of a switchboard instrument.

Fig. 2 shows the voltmeter in elevation, while Fig. 3 gives a plan; both figures being drawn partly in section, so that the working parts may be more clearly seen. The triple coil, C_1, C_2, C_3 (Fig. 1), passes over the poles of the three magnets, M_1, M_2, M_3 (Fig. 3), the direction of the winding being such as to cause the deflecting forces for each portion of the coil to be in the same direction. The current is led up to and away from the coil by very thin flexible silver strips attached to the points of the stationary pieces w, w' (Fig. 3).

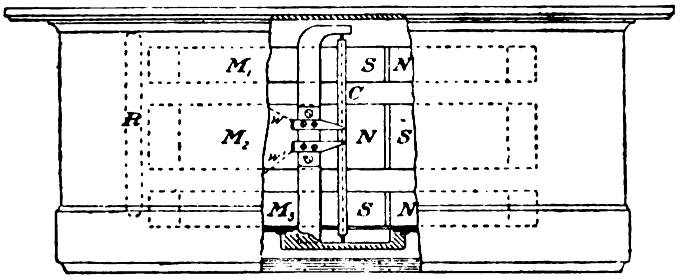

Fig. 3.

Conditions 5 and 6 are satisfied by specially shaping the air gaps, and we find that without sacrificing the quickness of motion of the pointer P too much, we can flatten the calibration curve at the working part of the scale so that 1-100th part of a volt variation in the pressure can be detected.

A bit of the scale, *full size*, is seen in Fig. 4, and, although large and bold, an additional means for indicating whether the pressure is correct or not is provided by means of the index I (Fig. 2). This index can be moved and set at any desired position by turning the milled head, H, which actuates a crown wheel segment, Q, carried by the ring to which the arm I is attached. This index arm is coloured *red*, while the pointer P and the arrow-head at the lower end of the index arm are coloured *black*. If the pressure be exactly right, the red index arm is entirely covered by the black pointer; whereas, if the pressure be high or low, red is seen to the left or right of the pointer respectively. An attendant can, therefore, see from a distance of many yards whether the pressure has exactly the desired value,

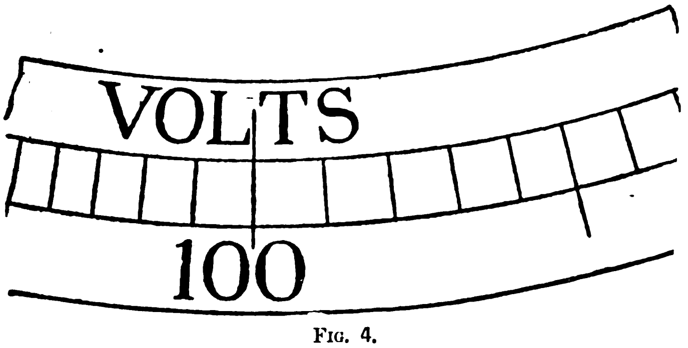

Fig. 4.

or is above or below it. The same milled head, H, works the arrangement for clamping the moving parts during transport; but this clamping device is so arranged that the moving parts cannot be clamped as long as the pointer is on any part of the graduated scale; hence there is no risk of the coil and pointer being accidentally clamped while the voltmeter is screwed up to the switchboard. To clamp the moving parts before removing the voltmeter, take out the two side screws that hold the voltmeter to the switchboard, and turn the instrument around the top screw until the pointer is deflected to the left of the graduated scale; then turn the milled head so as to bring the index up to the pointer, when the moving parts will be firmly clamped.

Lastly, the inside of the glass cover is coated with a layer of our transparent conducting varnish, described in the previous paper read to-night, and the instrument is thus screened from outside electrostatic action. Hence there is no fear of a change in the reading being produced by cleaning the glass—a very serious source of error, which is not uncommon with electro-magnetic voltmeters in actual use in electric light central stations.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, April 20th.

Institution of Mechanical Engineers.

7:30 p.m. General Meeting at 25, Great George-street. The following Paper will be read:—"Description of a Fluid Pressure Reversing Gear for Locomotive Engines," by David Joy.

Institution of Electrical Engineers.

8 p.m. Students' Meeting at 28, Victoria-street. A Paper will be read on "Secondary Batteries," by G. C. Allingham.

Royal Institution.

9 p.m. Evening Discourse: "Early British Races," by J. G. Garson.

TUESDAY, April 24th.

Royal Institution.

3 p.m. Afternoon Lecture: "Electric Illumination," by Prof. J. A. Fleming, F.R.S.

Institution of Civil Engineers.

8 p.m. Ordinary Meeting. The following Papers will be further discussed:—(1) "The Training of Rivers," by Leveson Vernon Harcourt, M.Inst.C.E. (2) "Estuaries," by Henri Léon Partiot.

WEDNESDAY, April 25th.

Society of Arts.

8 p.m. Ordinary Meeting. The following Paper will be read:—"Some Recent Developments of Photographic Chemistry," by Chapman Jones, F.C.S.

THURSDAY, April 26th.

Society of Arts.

4:30 p.m. Indian Section. The following Paper will be read:—"Municipal and Village Water Supply and Sanitation in the North-West Provinces and Oudh," by Sir Auckland Colvin.

Institution of Electrical Engineers.

8 p.m. Ordinary Meeting. The following Paper will be read:—"Cost of Electrical Energy," by R. E. Crompton, M.Inst.C.E.

FRIDAY, April 27th.

Physical Society.

5 p.m. The following Papers will be re :—(1) "The Mechanism of Electrical Conduction," by Dr. C. V. Burton. (2) "A Graphic Method of Constructing the Curves of Current in Electro-Magnets and Transformers," by Major Hippisley, R.E. (3) "The Design and Winding of Alternate Current Electro-Magnets," by Prof. S. P. Thompson, F.R.S.

Royal Institution.

9 p.m. Evening Discourse: "Action of Light on Bacteria and Fungi," by Professor H. Marshall Ward, F.R.S.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Another Amperian Rule.—So many rules have been published, giving the relative directions of the current and the lines of force or whirls surrounding it, that a writer in the *Electrical World*, of New York, has to apologise for introducing a new one. The apology in this case is the same as the one usually given, that the author believes it to be simpler and more easily remembered than the others. The present rule applies to the direction of the lines of force encircling the wire. To remember the direction of the magnetic whirls around a current, one has only to remember that if the current flows like the ink from a pen (that is, down the nib), then the direction of the magnetic whirls around this current will be the direction of the circular motion of the whole pen in drawing these whirls clockwise. It may be observed that the direction of such a spiral is the same as though one started to write the small letter *m* (magnetism). If, however, the whirls be drawn counter-clockwise, as though writing the letter *c*, the current represented by the flow of ink down the pen will be the one induced by the generation of these lines, as in transformers. The disadvantage of this kind of rule is that within half-an-hour of reading it the average man will not remember whether it ought to be "not *c* but *m*" or "not *m* but *c*;" and he will think he has to write *c*, when he has not, because *c* produces magnetism; and he will imagine that in the other case it ought to be *m*, because the magnetism induces *c*.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny

Editorial, Publishing, and Printing Offices :

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months. s. d.	6 months. s. d.	12 months. s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies :—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

INDICATOR DIAGRAMS.

In commenting on Prof. KENNEDY's lecture on Boiler Testing three weeks ago, we remarked that many ridiculous reports have been made on tests of engines and boilers by engineers ignorant of the principles as well as of the details of such work. An incomplete or inaccurate test of a boiler generally carries its own condemnation on its face, but a careless or incompetent test of an engine is more difficult to detect by mere inspection of the recorded tests, and the reproduction of indicator diagrams, more often useless than not, serves only to give a flavour of actuality to a number of more or less imaginary figures. In a thorough and complete report, specimen diagrams may be given, since they form part of the description of the engine, but where implicit confidence can be placed in the engineer, his results of indicated horse-power are to be accepted as they are given. Publication of the diagrams themselves gives no more information on this point, and is suggestive of the man who, having a house to sell, carried about a sample brick in his pocket. While nothing can tell more truly the characteristics of an engine, the action of its valves, its use or abuse of steam, and the power developed in the cylinders; no written record, whether penned by the hand of man or by a recording mechanism, is so hard to interpret. CÆSAR BORGIA could read between the lines when MACHIAVELLI wrote, and it is sometimes possible to affirm that the heel of a diagram shows that the indicator was on its stop at the end of the stroke; but who can say whether the cord stretched, or if the revolutions had been properly counted? Treacherous as indicator diagrams may be, it is probable that more engineers have deceived themselves, by

Digitized by Google

want of proper care in taking them, than have been deliberately misled by such subtle documents. Prof. KENNEDY gives the palm for downright lying to the ordinary steam-pressure gauge; but there is no artful fibbing or subtle prevarication here, the falsehood is of the most simple character and can be detected by any boiler insurance inspector on his annual visit. Prof. KENNEDY'S lot does not seem to be thrown among the old school of engineers, nor of those who have received and still follow the traditions of that school. We fancy that the practice of dividing an indicator diagram into ten parts and adding separately is still the rule rather than the exception, though no doubt the Finsbury student may never have heard of it. Planimeters, of course, afford the best means of measuring diagrams, but we hope that both Finsbury and other students have a second string in case no planimeter is to be had. We remember using up all the margins of a newspaper in measuring a number of diagrams in the train, using a two-foot rule for a scale; a planimeter certainly could not have been used under the circumstances.

Prof. KENNEDY'S advocacy of a simple rope brake with a spring balance and a weight instead of clumsy levers, tightening screws or complicated automatic appliances, is very welcome. New forms of Prony brake are continually being invented, and the idea of a brake costing only a few shillings seems to be a positive disadvantage in the opinion of some people. We shall not be surprised to hear of a Prony brake with electro-magnetic adjustments and a mirror and scale for reading. Fortunately in electrical engineering there is no difficulty in finding an absorption dynamometer, of moderate output, for any dynamo can be so used, with a resistance and a pair of instruments. In any electrical factory, the efficiency can be easily measured by the Hopkinson or, better, by the three-machine method. In the majority of cases in electrical work, the efficiency of a combined plant is to be measured, and the separate efficiency of the dynamo need not be determined. It is necessary, then, only to attend to the indicators and to the electrical measurements of the output. It is not easy to make a mistake about the output, unless inductive resistances are used with alternating currents, and this allows all the more attention to be paid to taking the diagrams.

Not only is practice necessary in this art, but practice on different kinds of engines. The mode of taking diagrams varies from the leisurely and dignified work in the engine-house of a large waterworks, down to the exciting occupation of indicating an express locomotive while strapped on to the buffer-beam. Like other arts, engine indicating has its refinements, and refinements overdone become fads. The engineer of one of the large shipping companies had a fad that the chief engineer of each steamer should indicate his engines every day. One of these officers was rather dense, and in fact quite unaccustomed to the work. The Company's engineer drilled him through all the details and at last got a good set of cards. "Bring me back some like these," he said as the vessel started for Melbourne. Every day the second engineer took two pairs of diagrams, and brought them to his chief, and every day the latter formally handed over two pairs of diagrams, duly initialled and dated, to the captain. One day the chief engineer was seriously ill. The diagrams were brought to him as usual. "Tear them up," he whispered. "Look in that drawer." The second engineer drew forth a packet of blank indicator cards, and a pair of neat zinc templates. "Scribe a set of diagrams round those," murmured the chief; "put in the atmosphere lines where you see them marked, and take them to the skipper."

NOTE ON THE BEST RESISTANCE FOR THE RECEIVER ON A LEAKY TELEGRAPH LINE.

BY DR. W. E. SUMPNER.

In a Paper just read before the Institution of Electrical Engineers by Prof. Ayrton and Mr. Whitehead it has been shown that, however complicated may be the manner in which leakage to earth occurs along a telegraph line, the receiving instrument which gives the best results will be such that its resistance is equal to the resistance of the line measured between the two terminals to which the instrument is to be connected. Thus, taking Fig. 1 (from their Paper) to represent the telegraph line, the best resistance for the receiving instrument q is that resistance which a Wheatstone's bridge would measure if connected with the end of the line Q and earth, the measurement, of course, being made by the false zero method if there are any electromotive forces, such as are represented by the battery b, either in the line or fault.

That this result should be true, whatever the law of distribution of the leakage along the line, seems at first sight very remarkable, and it is sufficiently important to warrant the inquiry whether its truth cannot be established in some simpler manner than by means of the rather difficult mathematical proof advanced by the authors of the Paper. It may therefore be of interest to give the following simple proof which occurred to the present writer while the Paper was being read before the Institution.

It will first be necessary to recall to mind a simple fact true of any network of conductors, however complicated. This property, which has been known for many years, is as follows. If *any* two wires contained in a network of conductors be called A and B, the current which is produced in B by inserting a unit electromotive force into A is exactly the same as the current which is produced in A by inserting a unit electromotive force into B. Thus in the network of wires forming an ordinary Wheatstone's bridge, if the insertion of v volts in the battery branch produce a current of a amperes in the galvanometer, then the insertion of v volts in the galvanometer branch will produce a current a amperes through the battery branch.

Referring now to Fig. 1 of the Paper, the effect on the receiver q will depend on (1) the current produced in q by the battery b, and (2) the sensibility of the receiver q. If the resistance of the receiver be r, its sensitiveness will be proportional to the square root of r; and the effect on the receiver is measured by

$$C\sqrt{r},$$

where C is the current produced in q by the battery b. The value of C depends on r, and we have to find that value of r for which $C\sqrt{r}$ is a maximum.

Now, from what has been said, the current C produced in the receiver q by the battery in b is exactly the same as the current which would be produced in b by a battery of the same voltage placed in the receiver circuit q. But if a battery of this voltage were actually placed in the receiver circuit q, the current which would be produced in q itself would be

$$\frac{V}{r+R},$$

where V is the voltage of the battery, and R is the resistance between Q and earth of the telegraph line. This current would flow along the line, branching off into the various leakage circuits, until the residue C passed through the battery circuit at b. The ratio of C to the total current in the arm q would depend on the resistances of the different branches of the network, but would not depend on r, the resistance of the branch q. So that, as far as variations of r are concerned, we may say that the value of the current C is simply proportional to $\frac{V}{r+R}$.

Thus the product $C\sqrt{r}$, to which the effect on the receiving instrument is proportional, is equal to

$$k\frac{\sqrt{r}}{r+R},$$

Digitized by Google

where k is a constant which does not depend on r. The value of r which makes this expression a maximum is

$$r = R,$$

or the resistance of the receiving instrument should be equal to the resistance of the line measured between the terminals to which this instrument is attached.

As this result has been obtained without any assumption with regard to the manner in which the leakage is distributed along the line, it must be true for all modes of distribution, however complicated.

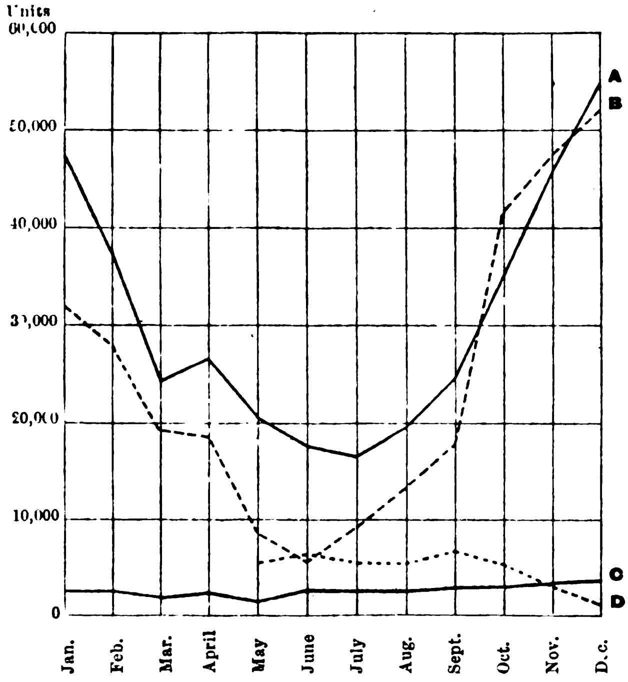
Moreover, it is clear that if a receiver, of resistance r, is used in any network of conductors, and if $f(r)$ represents the sensitiveness of the receiver, the best value of r will be such that

$$\frac{f(r)}{r + R}$$

is a maximum. Thus, if $f(r) = r^n$ where n is less than 1, it can be shown that the best value of r is $\frac{nR}{1 - n}$.

THE ST. PANCRAS ELECTRIC LIGHTING.

The statement of accounts of the St. Pancras Vestry Electric Light Undertaking for the year 1893 shows that this enterprise has progressed to much the same extent as the other metropolitan electricity supply businesses. The total capital expenditure up to December 31st last amounts, in



A General Supply at 6d. per Board of Trade unit, 1893.
B Ditto ditto ditto 1892.
C Ditto (Day Supply) at 3d. per Board of Trade unit, 1893.
D Ditto ditto ditto 1892.

round figures, to £96,000, some £7,000 having been spent during the year. The total revenue amounts to £15,021, as against £11,003 in 1892; the total outgoings amount to £8,809, as against £8,427. In other words, the revenue has increased 36 per cent., whilst expenses have only grown by 4·5 per cent. This big increase of income is, however, due largely to the so-called revenue from public lighting, which has more than doubled itself in 1893, whilst the sale of current by meter only brought in 17 per cent. more than in 1892.

Turning to the debtor side of the accounts, it will be found that 36 per cent. more revenue has been earned with an increase of less than £42 in the coal bill, and with an actual decrease of over £300 in the wages account. The management expenses, around which there must always be considerable ambiguity in municipal undertakings, appear to have been estimated on a different basis in 1893 than was the case in 1892; for instance, "stationery and printing" cost only £49 last year, against £276 in 1892; similarly, "general establishment charges" amount to only £148 in 1893, against £282 in 1892. Coming to distribution, the troubles with the mains, of which there have been so many rumours, have run up the cost of repairs and maintenance from £20. 16s. 2d. to £378.

The net result is that the St. Pancras undertaking made a profit of £6,212 in 1893, as against £2,575 in 1892, and not only paid all the current interest on loans but wiped off arrears, and paid off a little of the electric lighting debt.

Some of the curves which accompany these accounts are reproduced herewith; they show pretty plainly how relatively small the day demand for current remains, even at 3d. a unit.

THE BEST RESISTANCE FOR THE RECEIVING INSTRUMENT ON A LEAKY TELEGRAPH LINE.*

BY PROF. W. E. AYRTON, F.R.S., AND C. S. WHITEHEAD, M.A.

1. If there be a single earth fault at any one point of an otherwise good telegraph line, PQ (Fig. 1), it is easy to prove that the best resistance to give to the receiving instrument at either end of the line is equal to the apparent resistance of the line tested from *that* end when put to earth at the other end through a resistance equal to that of the signalling battery at that end. For example,

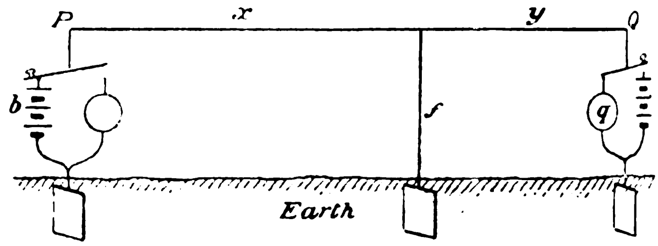


Fig. 1.

if we desire to know what should be the value of q, the resistance of the receiving instrument at the Q end, the line must be tested from the Q end (Fig. 2) when put to earth at the P end through a resistance, b, equal to that of the signalling battery usually employed at that end.

And the magnetic effect produced by an electro-magnet of given size, shape, and construction is proportional to the product of the current into the square root of the resistance of the wire with which the coil is wound. Therefore it follows that the magnetic effect of the receiving instrument at Q is proportional to $A\sqrt{q}$, and this has a maximum when q is equal to the apparent resistance of the line tested from the Q end and put to earth at the P end through a resistance b.

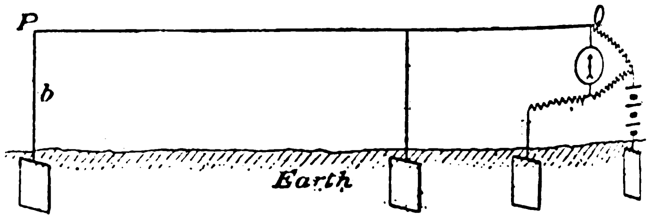

Fig. 2.

2. During the course of some lectures at the Guilds Central Technical College last year on faults on telegraph lines, the question arose whether the above result was universally true for a distributed leak all along the line, or only for a single earth fault; and, if this solution were not generally true, then what was the best resistance to give to the receiving instrument at the end of a telegraph line the leakage along which followed any law. The complete solution of this question shows that when the line is uniformly leaky the receiving instrument ought to have a resistance equal to the apparent resistance of the line when tested at the receiving end and put direct to earth at the sending end.

The resistance of the signalling battery does not in this case appear in the best value to give to q, but that arises from the fact that, whereas when we were dealing with a single earth fault we assumed that the signalling battery had a fixed E.M.F. and a fixed resistance, here we have assumed that the potential of the sending end of the line, was kept constant. Now this is the same thing as supposing that the signalling battery of fixed E.M.F. has an extremely low internal resistance. The two results are therefore the same.

*Abstract of a Paper read before the Institution of Electrical Engineers.

Digitized by Google

If the distributed leak follow *any* law, the general differential equation cannot be integrated, and we must deal with the problem of determining the best resistance to give to the receiving instrument at the end of the leaky telegraph line without actually integrating equation, and without expressing in an explicit form the value of the current that passes through the receiving instrument. The Paper shows by an elaborate mathematical calculation that, whatever be the nature of a leak on a telegraph line—whether the leak be a single one, or be distributed along the line according to any law of distribution—the same rule holds true for the best resistance to give the receiving instrument, viz., the receiving instrument at either end should have a resistance equal to the apparent resistance of the line when tested from that end and put direct to earth at the other end.

Speakers whose remarks are prefaced by an asterisk have returned their abstracts revised :—

DISCUSSION.

*Mr. W. P. GRANVILLE said Prof. Ayrton and Mr. Whitehead had laid down a law that the best resistance for the receiving instrument should equal that of the line as measured at that end, the distant end being put to earth. Might he suggest the following addition ?—that the measurement be made with a duration of contact approximately equal to the duration of contact used in signalling. This was especially important in the case of submarine cables.

*Prof. HUGHES said it was quite a treat to hear a telegraph Paper : it was so long since they had had one. He did not quite like the title of the Paper. The "best resistance" would evidently be none at all. What they wanted was conductivity, and they wanted the least resistance possible in the electro-magnet, provided they could get the magnet to do what they wanted it to do. He thought all tests of an electro-magnet should be made under conditions such as those in which they were used, particularly with rapid instruments on lines. He made a special study of the subject many years ago for his printing telegraph. The law then in general use, and he had seen it published since, was that the resistance of the receiving magnet should be equal to that of the line. His first magnet was so constructed. He always doubted the law, and made a special course of experiments to test it. He found, of course, that the self-induction of the magnet induced an apparent resistance also, so that the resistance of the magnet would be enormous. If they took an electro-magnet that was designed for a line of 500 miles, he found the best thing under all conditions of losses and varying conditions was to have the electro-magnet $\frac{1}{4}$ of that resistance. If the resistance of the line was very low through losses, he reduced the magnet resistance down to $\frac{1}{16}$. He was quite convinced that the resistance of all the receiving instruments throughout Europe was too high. The principle which he had adopted throughout in his instruments was to reduce the resistance as much as possible, and he had experimented on lines of thousands of miles in length. These experiments were not laboratory experiments, but involved watching days and days and months and months to see the effects on each line, and he had never met with a case where a large resistance, equalling that of the line, would work as well as one which was a quarter of that of the line. Therefore, he thought it was a great mistake to have *too* high a resistance in the magnet. The tendency of Prof. Ayrton's method would be to lower the resistance of the magnet. But when they designed electro-magnets for telegraph instruments they could not state any given law for one electro-magnet, because telegraph instruments were all constructed up to a certain model, and the models were sent indifferently all over the country, one working over 500 miles, one over 300, and one, perhaps, on a short circuit. Makers never knew where their instruments were going, and the telegraph people did not pay any attention to the resistance. So the makers had to try and find out the average length of line and the average conditions, and design their electro-magnets to meet the average conditions. He did not know what resistance Prof. Ayrton would choose for a 5,000 ohm line. His Paper was not very clear with regard to that.

*Prof. AYRTON, in replying, said he was sorry that, after what the telegraphists had said so often as to their interests being neglected, and that they never had telegraphic Papers, and so on, they did not come forward and discuss a telegraphic Paper when one was read. If they would only come and say that the Paper was wrong it would be something. Of course, in presenting the Paper they did not wish it to be supposed that in the long practice of telegraphy people had not got some notions of what was the best sort of resistance to give the receiving instrument. He remembered that the late Mr. Schwendler, twenty-two years ago, published a rule that the resistance of a telegraph relay should be equal to $\frac{5}{8}$ of the true resistance of the line wire. That did not mean the resistance tested as he had described, but the true resistance of the wire neglecting all leakage. He (Prof. Ayrton) was not aware, however, that this problem had ever before been examined mathematically in a perfectly general form, so that the solution should be applicable to any law of distribution of leakage along the line. As Prof. Hughes had said, the title was, perhaps, a little misleading. It might appear that a telegraph instrument was better if it had a certain resistance than if its coils were wound with wire of infinite conductivity, what was, of course, meant was that resistance was a bad thing while many convolutions were desirable ; but inasmuch as with no material could they obtain convolutions without resistance, there was a certain resistance which was the best for the instrument under particular conditions, and, as they had shown, generally the best resistance for a receiving instrument was the apparent resistance of the line as tested at the receiving end and put to earth at the sending end. The question had been asked, what was the good of obtaining a rule which depended on the insulation of the line? The insulation of the line changed from day to day, and they could not be perpetually altering the resistance of their receiving instrument. The answer was, when the line was in good order and the insulation high, there was no difficulty in signalling ; it was only when the insulation was low, through rain along the line, that the trouble occurred. Therefore he thought it would be best to adapt the resistance of the receiving instrument to suit the line in its worst normal condition. Prof. Hughes had asked what resistance he would give to an instrument if the resistance of the line was 5,000 ohms. He thought he would find a good deal higher than 300 ohms would be good. In India they did not make a number of instruments with an average resistance and send them out so that a line 50 miles long had the same resistance as lines working across the country from Calcutta to Bombay, but they wound the relays to suit the particular line it was to work on. In that country they were suffering, some twenty years ago, from having much too low a resistance, whereas Prof. Hughes had apparently been troubled by his relays having been wound with too high a resistance.

TRANSPARENT CONDUCTING SCREENS FOR ELECTRIC AND OTHER APPARATUS.*

BY PROF W. E. AYRTON, F.R S , AND T. MATHER.

It is well known that electrostatic instruments require to be screened from outside electric disturbance, in order that their indications may be correct ; but it is not so generally recognised that instruments intended to measure small forces, such as certain types of *electro-magnetic* voltmeters, delicate vacuum gauges, &c., are liable to give wrong readings from an electric attraction being exerted on the pointer, such as is produced by the glass cover when it is touched or cleaned.

There is on the table here a well-known type of gravity *electro-magnetic* voltmeter, which may be found on the switchboards of many English and continental electric light stations. At the present moment its terminals are not connected with the electric light mains of the building, so that it should indicate zero pressure. Let me, however, but stroke the right-hand side of the glass cover with my finger, and the pointer, as you see, at once turns to 80 volts or more. Conversely, let the terminals of the voltmeter be connected with the electric light mains: the pointer should point to about 100 volts, for that, as you know, is the pressure supplied by the Westminster Company. The voltmeter appears to be indicating correctly ; but, on stroking the left-hand side of the glass cover, the pressure, as read by the instrument, appears to suddenly fall to some 40 volts. And a similar effect is produced if a piece of wash-leather or dry waste be used in place of the finger.

If, then, it is possible to cause this instrument to indicate at will 60 or 80 volts too high or too low, how impossible must it be or feel sure that the glass cover—which is, of course, maintained in a dry condition in a hot engine-room—has not been electrified by some accidental touch of the coat sleeve sufficiently to cause an error of 3 or 4 per cent. in the reading of the voltmeter !

We find that it is not merely with this particular type of voltmeter that an error can be produced by stroking or rubbing the glass cover, for other electro-magnetic instruments that we have tried can also have their pointers deflected in the same way, but not to the same extent.

Nor, of course, is this source of error in any way connected with a voltmeter being an instrument constructed to measure an electrical magnitude, for it would equally exist if the glass were clean and dry and the controlling force remained of the same magnitude, no matter what was the quantity the instrument was constructed to measure. For example, on the table there is a vacuum gauge the wheel-sector-pinion of which has been replaced with an Ayrton-Perry magnifying spring. This gauge is, no doubt, very sensitive, for you observe that the pointer moves even when I produce an extremely slight diminution of pressure by rotating the short length of india-rubber tube as slowly as I can ; the change of pressure on pinching the tube, or even on dropping it, is indicated by the pointer. On the other hand, the pointer is of glass, and, therefore, is not suitable for being acted on by an electrostatic force ; still, a stroke on the glass cover, as you see, causes the pointer to deflect through several degrees.

It has been known for a long time that it is possible to screen an instrument from such outside electrostatic disturbances by surrounding it with a metallic cage composed of wire or of strips of tinfoil. Such a method of screening, however, has the great disadvantage that it renders it difficult to observe the exact position of the pointer from a distance, for the wires or strips of tinfoil cover up the pointer more or less. We therefore thought of placing the pointer underneath the metallic dial of our electrostatic voltmeters, and of only allowing the tip to project through a slot in the dial plate. But this method we abandoned on trying it eighteen months ago, for to make the screening good, the visible part of the pointer must be reduced to a spot, and the exact

* Paper read before the Institution of Electrical Engineers, April 12th,

Digitized by Google

position of this spot we found less easy to read at a distance of several feet than that of a long black line, which is the appearance of a pointer when it is visible along its whole length. This method of screening has, however, we understand, been recently adopted by a firm of instrument makers.

We next considered whether it was not possible to make a perfectly transparent conducting screen, so that, while the electrostatic screening of the pointer should be practically perfect, the pointer and dial should be as easily seen as if the screen were not present. Our first idea was to make the glass cover double, and to insert between the two sheets of glass a layer of clear conducting liquid. Fearing, however, trouble from leakage of the liquid, or from the liquid becoming gradually turbid and giving the dial a dirty appearance, we turned our attention to depositing films of solid matter on the inside of the glass cover, or shade, of sufficient thinness to be practically transparent, but with the solid particles near enough together to be conducting. We tried smoke, silver deposited in layers of various thicknesses, mercury vaporised and deposited, sal-ammoniac vaporised and deposited, &c., but we were quite unable to obtain in this way both transparency and electric conduction.

After a conversation with Prof. Boys, when discussing the problem that we were then engaged in solving, we commenced experimenting on varnishes, with the view of arriving at a varnish which should be as hard and as transparent as *clear* shellac, but which, instead of being an insulator like shellac, should be a sufficiently good conductor to allow of the instantaneous production of an induced electric charge to balance the electrostatic action of any outside body. Glass plates were coated with gum, with coaguline, with the gelatinous electrolyte used in accumulators (composed of sodium silicate and dilute sulphuric acid), with isinglass dissolved in acetic acid, with gelatine dissolved in acetic acid, with isinglass dissolved in a mixture of acetic and sulphuric acids, and with gelatine dissolved in the same mixture. After much experimenting, we arrived at the following two methods of coating a glass cover, or shade, which gives perfectly satisfactory results:—

No. 1.—Dissolve ¼oz. of transparent gelatine in 1oz. of glacial acetic acid by heating them together in a water bath at 100°C. To this solution add half the volume of dilute sulphuric acid which has been prepared by mixing 1 part of strong acid with 8 of distilled water by volume, and apply the mixture while still warm to the glass shade, which should be previously polished and be warm. When this film has become very nearly hard, apply over it a coating of Griffith's anti-sulphuric enamel.

Method No. 2.—Thin the gelatine solution, prepared in the manner previously described, by the addition of acetic acid (say 2 volumes of acid to 1 of the solution), and, after polishing the glass, float this thinned solution over the glass cold. Drive off the excess of acetic acid by warming, allow the glass to cool, and repeat the floating process, say, twice. Thin the anti-sulphuric enamel by the addition of ether, and float it over the gelatine layer applied as just described. Expel the ether by heating, and apply a second layer of this thinned anti-sulphuric enamel.

With experience, such as Messrs. Elliott and Messrs. Paul have at length acquired after much practice, a layer can be applied, either according to method No. 1 or No. 2, so that, when finished, it is quite hard to the touch, and so transparent that it is only by looking at the glass plate obliquely that the presence of the varnish can be detected. It is also so conducting that when a potential difference of several thousand volts, alternating with a frequency of 200, is set up between the needle and inductors of one of our electrostatic voltmeters, the pointer, which is metalically part of the needle, is not visibly attracted by a metallic rod held just outside the glass close to the pointer, this metallic rod being electrically connected with the stationary inductors.

Without experience, however, it is somewhat difficult to apply the coating so that it is not either cloudy, or a comparatively poor electrostatic screen, or both.

This second electromagnetic voltmeter—which, like the former, has been kindly lent us by Mr. Barley, of the Knightsbridge electric light central station—looks exactly like the other one, and, indeed, behaved exactly like the other one when we received it. It has, however, had a layer of our transparent varnish applied on the inner side of the glass subsequently, and you will find that you may rub the glass as much as you like, or even hold a rubbed stick of ebonite near it, without producing any effect on the pointer.

Again, these two clear glass shades, belonging to gold-leaf electroscopes, are one of them coated with our varnish, and the other not. Which is the uncoated one is at once apparent from the alteration produced in the deflection of the gold leaves when I approach a stick of rubbed ebonite near the lower part of the glass shade of the uncoated one, for no such change in the deflection is produced, as you see, when the ebonite rod is brought near the glass shade, which is protected by a layer of this varnish applied on the inside.

The following is an abstract of the discussion on the Papers on a Station Voltmeter and a Transparent Conducting Screen. Speakers who have returned their proofs revised have their remarks prefaced by an asterisk :—

DISCUSSION.

Mr. MORDEY thought the open scale arrangement of the voltmeter described was the most important feature that had been brought out in direct-reading instruments for a long time. Instrument makers had as a rule divided their scales to get proportionalities in the scale ; proportionalities were very nice things when one got them, but it was often more important to have a very large and open scale. He hoped the authors would pursue their labours further and give them alternating-current voltmeters with the same features. He must congratulate the authors on the transparent conducting screen. He thought perhaps he was the first to draw Prof. Ayrton's attention to the necessity for something of the sort.

The CHAIRMAN (Mr. Crompton) said the phenomena of the electrification of the glass of instruments was very well known to every electric light station apprentice, and the way of preventing it becoming a serious nuisance was also well known. The way was, after wiping the glass, simply to touch it with the finger. So far as he knew no inconvenience had ever arisen from the phenomena ; it was, in fact, rather interesting, and rather a slow thing to get the instruments to act, as they had been made to do that evening by being carefully warmed up by means of the lamps in front of them. He did not think Prof. Ayrton would have got the phenomena at all but for the fact that they had been having weather more like that usual in the south of Spain than an old-fashioned English spring. He thoroughly agreed with the points raised as to the requirements of a good station voltmeter ; but he fancied that Prof. Ayrton had but carried out what many of them had carried out before, and that some of his improvements were not new. The pointer which he had described was identical with the form which his (the speaker's) firm had used for some time past. The clamping device appeared also to have been used by them and others. The way in which Prof. Ayrton got over the difficulty by using a moving coil, which was a very beautiful development of Mr. Weston's method, had only one serious defect, that it was so costly. Mr. Weston's instruments were so costly that it was a luxury to have one in each station, and he was afraid that when they multiplied Weston's coils by three, and applied as much care to producing the three permanent magnets as Mr. Weston applied in producing one, it would be found that the instrument was so costly as to be scarcely within the reach of many of them. The voltmeter of modern times had to be made and sold for £3 or £4. By employing instruments with soft iron deflecting pieces, as astatic as possible, so as to provide them with an exceedingly strong field, they did not get results sufficiently good for their purpose, which was to have in the station one good electrostatic voltmeter, either a Sir William Thomson's multicellular form, or something resembling that, and have that as the voltmeter for reference, and have a large number of voltmeters on the switchboards sufficiently close to the reference voltmeter, so that the errors at different times of the evening might be known and noted. The errors might be 1 per cent. or 1½ per cent. ; but those who were working at the switchboards were accustomed to them, and could make allowances for them. They found no difficulty in obtaining voltmeters for small sums which were accurate within that limit of error. He would point out to Prof. Ayrton that he would not make a very sensitive instrument with three coils arranged in the way he described, for the weight of those coils was something considerable, and with the balancing weight added would be so much for the pivot to carry that the instrument would be much more sluggish than one with a deflecting piece, that deflecting piece acting as the weight, or else having an additional weight of small magnitude. As regard the open scale, he thought equally open scales had been obtained by several people.

*Prof. AYRTON, in replying, said Mr. Crompton rather implied that he had manufactured a defect in the measuring instrument, and then shown how to get over it, and that it was rather a feat to show the defect. Now, Mr. Mordey was not, as a matter of fact, the first to draw his attention to this electrostatic action, because in a certain central electric lighting station in London of no small importance, four years ago, he was shown a row of those instruments, and was told they could not be used because of the difficulty that the pointers were attracted when they cleaned the glass. Mr. Crompton said it was quite easy to get over the difficulty—one had only to touch the glass with your finger. Curiously enough, a central station engineer had written to him to point out the bigger effect produced when the glass was touched with the finger. This engineer went on to say, which was wrong reasoning, for very often central station engineers did reason wrongly—I think you will have to put a varnish outside as well as inside, because not only do you get an effect when you rub the glass, but you get a much bigger effect when you touch it outside with your finger.—It was not an easy matter to de-electrify glass by simply touching it with the hand. As regards warmth, that was, of course, the difficulty. With the warmth which they could not avoid having in a central station the instruments were as dry as, if not drier than, the instruments he had on the table with the glow lamps in front of them, and the effect was as noticeable. As to the clamping device, it was fair to themselves to say they had used this particular device in connection with their electrostatic voltmeters which were not the subject of the Paper before them, for some three or four years. Mr. Crompton said the use of a moving coil with a permanent magnet produced a sluggish instrument. In that he might say without hesitation Mr. Crompton was absolutely wrong, because it was well known that you could increase the force to any amount you liked if you only had a sufficiently powerful permanent magnet. The proof was that the watts employed in this instrument exhibited were only 1½ at 100 volts, and they got a pretty quick motion of the needle. was the fact of Mr. Weston taking the idea of using a

Digitized by Google

moving coil and a powerful permanent magnet which enabled him to make portable voltmeters of very high resistance. No portable voltmeter was ever made of over 10,000 ohms before Mr. Weston made his. How did he obtain it? Simply by utilising the principle that Maxwell was the first to point out, and that Lord Kelvin had employed in his syphon recorder. They did not use any controlling weight in their instrument; they used a weight to control it, but not an auxiliary weight. The weight was the weight of the coils themselves, and they said that with 3 per cent. of the whole resistance wound on the moving triple coil they could get force enough to give a quite sufficiently quick motion. In reference to the price of instruments, it must not be forgotten that the Weston instruments were made in America. American workmen were paid twice as much as workmen here, and they were able to keep up those high prices because of the very heavy import duty levied on goods coming from other countries. They must not, therefore, jump to the conclusion that because the Weston instrument was an expensive one, other instruments using a moving coil must be equally expensive.

A UNIVERSAL SHUNT-BOX FOR GALVANOMETERS.

At the last meeting of the Institution the following additions were made to the discussion on the above Paper (see *The Electrician*, April 6). Speakers who have returned their proofs revised have their remarks prefaced by an asterisk:—

*Prof. AYRTON, having read the addition to his Paper, said since the Paper was read there had, of course, been criticisms of the method they proposed for shunting. One of the criticisms was mistaken, because it was based really on a wrong conception of the way in which shunts were used. The objection that had been made was this: In Fig. 4† (*The Electrician*, April 6, p. 629) the method they proposed, the current that passed through the galvanometer, the largest current, was less than the current of copper, and was supplied when the galvanometer was bought; it was by a good maker, it was screwed down close to the galvanometer, and had been so for years; it had been kept in a basement, where the temperature did not vary very much, and still the comparison of the two currents with the same galvanometer was not as accurate, using this shunt supplied with the galvanometer, as the comparison of the same two currents, using their universal shunt, made without any reference whatever to this particular galvanometer, the coils having been wound by a person who had never seen it and knew nothing of the resistance of the galvanometer. All uses of the deflecting galvanometer were either to measure two currents or to measure two rushes of electricity. He would now take two condensers. Taking the ordinary method first, one condenser having 1/3 of a microfarad capacity, the other unknown, but somewhat larger, then with the same electromotive force and discharging successively through the same galvanometer they obtained two deflections. If they simply took the swings using the ordinary shunt the apparent ratio of the second to the first was 99·38. As a matter of fact, the second capacity was somewhat greater than 100 times the first. It was stated in the criticism he was referring to that shunts had "a definite damping constant"—ordinary shunts, of course. He was not quite sure what that meant. But if it meant that the same correction was to be applied in all cases, then it was wrong. Moving the controlling magnet from the position it was in to another position a little further up, and performing exactly the same experiment, with the same galvanometer and the same ordinary 1/99 shunt, the ratio of the swings was 91·87. Not only were both these wrong, but they were not wrong by anything like the same percentage. One was 3 or 4 per cent. wrong, and the other about 12 per cent. Now, using their own shunt, which was not made for this particular galvanometer, they got a ratio of 103·5 for the capacities of the two condensers when the controlling magnet was down, and 104 when it was up (*see* Table); as a matter of fact, the true ratio was 103·45. Therefore, those two results obtained with the new method of shunting were practically the same; and not only were they both the same, but they were both right; that was to say, no correction would have to be applied, hence they got much

in the mains. When the main, M_2, was moved to the dotted position no doubt the current then passing through the galvanometer was one-tenth of what previously passed, but not one-tenth of the current on the main. Therefore it was contended that the method was not capable of very great application. That would be valid if Thomson reflecting galvanometers were instruments of invariable insensibility and were provided with direct-reading scales graduated in micro-amperes. But as they all knew perfectly well, owing to the change of astaticism of the needles from day to day, the change of position of the controlling magnet and of the masses of iron in the neighbourhood, the constant of the Thomson galvanometer had to be taken whenever they had to use the instrument. Now it was just as easy to take the constant of the galvanometer when permanently shunted with a resistance r as when there was no such shunt. There was nothing like an example. He had two currents that he wanted to compare (*see* Table); one was a current of a micro-ampere, the other was a current of x, the value of which he did not know. He would take his own method first. The micro-ampere was the micro-ampere in the mains. When one micro-ampere passed along the main the deflection was 536·7. Then sending the current x, a current much larger than the first, through the main, he changed the position of the main wire, and found the deflection to be 536·6. From this he knew the ratio of the two currents in the mains to be 99·99. As a matter of fact, the true relation of those two currents was exactly 100. The currents were made so that one was exactly 100 times the other, without any reference whatever to their universal shunt-box. Now let them consider the ordinary method. In the ordinary method they would send one micro-ampere through without a shunt, and would get a deflection of 590·6; then, putting on the 1/99 shunt, the deflection was 588·4. One current was thus 99·63 times the other. That was not so accurate. This shunt was made

† Prof. Ayrton points out that this figure was incorrectly given in our last issue. The letter c should refer to the point where the dotted line joins the wavy line, and r is the *whole* resistance, not a portion only as indicated.—[ED. *E.*]

more easily an accurate comparison of two condensers in this way than in the ordinary way. Mr. Hockin's mathematical analysis showed that the error in comparing capacities with the ordinary shunt depended on the position of the controlling magnet, and, therefore, the correction which had to be applied for one position of the controlling magnet, was quite different from the correction which had to be applied for a different position of the controlling magnet, but he doubted whether that difficulty was generally recognised. He thought, therefore, that they were justified in saying that this method was more universal and gave much more accurate results than the shunt which was specially prepared for a particular galvanometer. As to price, he thought the instrument maker's estimate, which he quoted of the prices for constructing different kinds of shunt boxes, afforded additional confirmation of the fact that the method of Mr. Mather and himself had many advantages.

*Mr. CHARLES BRIGHT said at present Prof. Ayrton's shunt had one doubtful feature. By his arrangement they would not have the full advantage of using a sensitive Thomson galvanometer for testing high resistances, because when they had this shunt permanently in multiple arc with a galvanometer they would do away with the usefulness of an exceedingly sensitive galvanometer. There were many cases where they wanted the most sensitive arrangement possible for testing high resistances.

*Prof. AYRTON said Mr. Bright was perfectly correct in cases where the current to be measured was so extremely small that to detect it at all bordered on the limits of the possible. It was certainly better, then, to have no shunt to the galvanometer, or to have the value of r very large. But that was very exceptional. Generally, with the delicate galvanometers of the present day, and having a fair number of cells, when testing the insulation of a condenser, or the resistance of a piece of gutta-percha cable, they were not measuring currents bordering on the limits of the power of the galvanometer, and in that case, if the resistance was fairly high compared with the resistance of the galvanometer, he did not see any objection to having the galvanometer, g, *permanently* shunted with any resistance, r, which was fairly large compared with g.

UNDERGROUND MAINS.

The following is an abstract of the adjourned discussion on the papers on Underground Mains read before the Northern Society of Electrical Engineers, by Mr. J. H. Rider and Mr. S. V. Clirehugh, and published in our issue of March 16th last:—

Mr. WOOLER would have liked to have heard some more definite advocacy of a particular system of mains, and sound reasons given for such opinion, because it was patent that every class of mains had their advantages and disadvantages. For instance, bare copper conductors laid claim to economy in first cost. Well, that only applied where a large quantity of mains were required. One advantage which bare copper certainly did possess was the facility with which service connections could be made. A clamp sweated on to the leading, in wires, then bolted on to the bare copper and the work was done. Whereas with vulcanised rubber cables the minimum of time within which two men could attach a consumer was not within the range of an ordinary working day. What, however, he considered to be the most serious defect in the use of bare copper was the space required to build the concrete culverts and their having to be frequently intersected with lengths of cables where headway cannot be obtained for the conduit. Then, again, the copper tape of required cross-section was only manufactured in lengths something over 100 yards, so that it might be taken for granted that the average continuous length from street corner to street corner did not much exceed that, and one got a mixture of a length of copper strip, short length of cable, another length of copper strip, another bit of cable, and a number of joints, no matter how carefully made, must assuredly reduce the conductivity, and far more serious still, be calculated to engender a source of electrolysis by dissimilar metals used in the union. With conduit explosions, in the case of cables on the draw-in system, all the injured ones had to be pulled back to the next coupling box on either side, renewed, jointed and vulcanised, which was a lengthy occupation; but if bare copper was concerned, the strip and porcelain insulators might be blackened, which with cleaning and a little adjustment would soon be rectified. Much was said at the previous meeting upon the subject of vulcanised rubber joint making. He must reiterate that in actual practice that was a costly operation. Particular emphasis was laid upon the importance of extreme cleanliness; but, as was said at the last meeting, it was all very well to give a workman orders to go and do so and so, but the actual performance might be difficult. Imagine being stuck in a hole several feet deep, surrounded on every side with excavations, and the rain, perhaps, coming down, the water making puddle with which the men were besmeared, and nevertheless they were to be perfectly clean. Another point he wished to touch upon was Mr. Clirehugh's mention of soft soap to ease the cables when being drawn into the pipes. Very particular care should be taken to see that the pure neutral soap was used, otherwise the acids and other objectionable ingredients might have a very injurious effect upon the covering of the cables.

Mr. CORLETT said that since the last meeting he had obtained some reliable figures as to copper strip. In Hove in wet weather the average insulation resistance ran from 0·35 to 0·5 megohm per mile, and in dry weather from 2 to 3 megohms. With regard to the actual cost of laying and maintaining copper strip, he found from figures he had had from Kensington Station that the total cost for laying the system for Kensington amounted to £55,000. Of this amount upwards of £30,000 was spent in 1890, and nearly the whole of the remaining sum was spent in 1891. The figures for maintenance, including all repairs to surface boxes caused by wearing away of cement, trifling modifications in pavement, resetting of boxes caused by reflagging, &c., were as follows:—In 1888 the maintenance bill was £24, in 1889 £40, in 1890 £56, in 1891 £98, in 1892 £364, and in 1893 £280, making a total altogether of £862 for the six years. Taking the whole as spent in four years instead of six, and taking the capital outlay as £50,000, the cost of maintenance works out at 0·43 per cent. per annum.

Mr. CALLENDER said that previous speakers seemed to consider vulcanised rubber as the only material used for underground mains. This was hardly the fact, for when they looked into details it was astonishing how little rubber actually was used, and for distributing mains especially to what an extent it was being superseded. He found that up to date there were 82 stations in the United Kingdom under the Electric Lighting Acts which were either in actual work, or for which definite contracts had been given out for mains. Now these 82 stations had their mains insulated as follows:—

	39	Exclusively by materials other than rubber.
	6	Strip systems with bitumen cables.
	5	Network of cables other than rubber, but part of high-pressure feeders of rubber.
50——		
	19	Rubber insulated throughout.
	7	Strip systems with rubber cables.
26——		
	6	Common to all, the cables being insulated by rubber and bitumen, or of the lead-sheathed type.
—		
82		

Unlike most cable makers, he had laid a good deal of culvert, and knew exactly its weak points. The only town with which he was acquainted which was thoroughly suitable for culverts was Dundee. The station there was on a hill, and the lighting area close to the sea. Unfortunately, towns with such natural advantages for draining one's culverts were not often found, and he could not consider strip and culvert as universally applicable or advantageous.

Mr. E. H. NISBETT thought some account of their experiences in the City of London would be of interest. If low-tension mains were referred to by Mr. Rider, he (Mr. Nisbett) was quite in accord with the suggestion that a "built-in" system should be used for the distributors, and a "draw-in" system for the feeders, as in that case the cost of the conduits was a relatively small item, but for high-tension work the conduits might cost actually more than the cable itself. Suppose they took the case of a feeder having ultimately to transmit 200 kilowatts, and it was determined to put down for immediate requirements only one-third of the total quantity of copper. In the case of a three-wire distribution, they might then have to at once put down one-third of 1 sq. in. of copper, say 0·33 sq. in.; a triple concentric cable of this section would cost about £1,500 per mile and a conduit to contain it with two spare "ways" would cost £350 per mile, making an immediate outlay of £1,850 (neglecting trench work) and an ultimate expenditure of £4,850 per mile for the complete feeder. Against this an armoured cable of 0·33 sq. in. section would cost £1,600 per mile, showing a lower initial expenditure, but the ultimate cost would be £4,800 and £400 for second and third trenchings, making a total of £5,200 per mile, or more than the "draw-in" system. Now in the case of high-tension work it was different; the same feeder working at 2,000 volts would be 0·1 sq. in. section. A cable of one third of that section would cost £155 per mile, and the culvert to contain it £310, bringing the total immediate outlay to £465 and the ultimate outlay to £775 per mile. Now for £465 per mile one could purchase an armoured cable of 0·1 sq. in. section area, and so at once put down the whole of the copper estimated to be required. Mr. Rider mentioned the distance apart of feeding points as being not more than 250 yards if the distributing mains were to be kept of a reasonable size. He thought that was putting the feeding points very close together. In the City of London they had provided for an average demand of 4·5 8-c.p. lamps per yard of frontage. He had made some experiments in the City, from the results of which he was enabled to state that the impedance drop in the type and size of cable that Mr. Rider was using was about 10 per cent. over the ohmic drop at 200 volts, and the loss in the lead and iron sheathing about 50 watts per mile, not a large amount perhaps, but certainly worth taking into consideration. He must take exception to Mr. Clirehugh's statement that india-rubber cables "stand at the top from a scientific point of view." What was the scientific point of view of a perfect cable? He had there a sample of a cable which had been working only two years; when it was laid down in the City the india-rubber was apparently perfect; it had lately been examined and several lengths had been found in which the rubber was very badly cracked and unfit for further use. Impregnated fibre cables generally had the great advantage that they could not be adulterated. With rubber cables one never knew within 20 per cent. how much adulterant it contained. As regards flexibility, they lately tested a piece of 0·3 sq. in. triple concentric paper cable of 1½in. diameter, bending it to a 30in. radius, and straightening it again without damaging it. It then successfully withstood a pressure of 4,500 volts, although only designed to work at 200 volts. A piece of rubber cable sold to the City Company for low-tension work broke down under the same pressure. Mr. Clirehugh stated that under certain circumstances it was possible to draw 80 to 100 yards of cable in one length. In the City they had drawn as much as 185 yards of cable at one time, the length weighing 2 tons. Mr. Wilkinson was now putting down paper cable at Southport, and he had lately been testing them to 20,000 volts without any sign of a breakdown, the thickness of the dielectric being only [illegible]in. The cables supplied to the City of London Company, and having to work at 2,000 volts, were tested after being laid and jointed to 10,000 volts.

Mr. G. E. PREECE (Vice-President) wrote that amongst the various classes of conduit described, no mention was made of the form introduced by the "International Subway Company," and lately entirely used in Portsmouth for the town lighting. It figured up much cheaper than ordinary piping, and it had one very great advantage, that special facilities were provided for jointing and leading off from the mains to trenches or consumers' premises. One advantage of the iron pipe system which had not been mentioned was, that owing to the lengths of pipe used, and the excellence of the jointing, pipes did not give way owing to the inequality or subsidence of the ground, and the cables were not prevented from being drawn out as had occurred in many of the built-up drawing-in systems. In the lead-covered cable there was no doubt but that they had now arrived at a very high pitch of perfection. But he could not help thinking that whilst such important improvements have been made with the core itself, no improvement had been made with the lead covering, which was practically the vital point in that form of cable. Indeed, he was inclined to think that from what he had seen, and from information obtained, that the quality and durability of the lead used at the present time was not so good as that employed in the past. As regards the durability of vulcanised rubber, he showed two samples of aerial cable sent by Mr. Higgins, of the Exchange Telegraph Company. They were suspended in the air in November, 1873, and taken down in 1893, nearly 20 years after, on account of the house to which they were attached coming down, and not on account of any fault in the cables. The samples and letter were sufficiently explanatory. Some remarks had been made on the question of jointing vulcanised cores. There was really no difficulty about it, but for absolute perfection in a joint none but skilled workmen should be employed. Unless a jointer possessed absolute "cleanliness" he would never make a reliable jointer. That was the great secret in rubber jointing, and it was so in gutta-percha jointing. Some men were physically unfit for jointing. He quite agreed with Mr. Rider where he said in his Paper, "I venture to think that a combined system of drawn-in for the feeders and built-in for the distributing mains, offers a number of advantages." That plan was

Digitized by Google

adopted with great success at Morecambe and would be applicable to a great many places.

Mr. RIDER, in reply, said: My chief point was using "drawing-in" system for feeders and armoured system for distributors. Mr. Mountain and several others agreed with that. Mr. Nisbett did not, and pointed out that an armoured feeder could be put down more cheaply. The Board of Trade had limited him to 100-H.P. for his transforming centres, with the result that a cable for 200 kilowatts was out of the question, and as he should only put down a feeder for one feeding centre, the advantage of an armoured system was not so apparent. My great point was a "drawn-in" system for feeders. Where they had to go to distant districts they had to put an entirely new feeder down, and that feeder had often to go through the district already lighted. Bristol had just started when an outlying district wished to be supplied, and there was a terrible hubbub because they could not tap on to their present mains. There was a fine row about it, and electric lighting could not afford to give any cause for heavy discussion in that way. Mr. Mountain spoke of splitting up a network, instead of joining the whole into one large network. In a big town if a fault occurred on the other side of the town in the same network, the whole system was jeopardised. In splitting up the network, they had the advantage of a break down in one part not affecting any other.

Mr. S. V. CLIREHUGH, in reply, said the main feature of the discussion had been the discussion as to the difficulty of vulcanising joints in india-rubber cables. There had been a certain amount of disagreement on the subject, even among manufacturers of rubber cables; but they had all stated that the difficulties of vulcanising had been over-rated, though they admitted that it was desirable, nay necessary, to send the jointers to the manufacturers to be taught to vulcanise properly, with the result that those men, upon whom one had no hold, were taught a trade at one's expense, and afterwards, of course, demanded very high wages. He believed the London supply companies were paying vulcanisers 10d. and 1s. per hour, and found it difficult to procure them at that.

THE CABLE-STEAMER "DUPLEX."

The trial trip of the cable steamer "Duplex," formerly the "Nentwater," took place over the measured mile off Hartley on Saturday, the 7th inst. She was originally built by Messrs. C. Mitchell and Co., of Low Walker, and in December last was purchased by the Eastern and South African Telegraph Company to be fitted and used as a submarine cable maintenance ship. The vessel was then completely dismantled of all her original fittings, including the old machinery, and the form and construction of the forward end of the ship was entirely altered to carry the bow sheave for the cable picking-up gear, by the construction of a clipper bow in place of the ordinary straight stem. The contract for the reconstruction of the vessel, including the building of three cable tanks, capable of containing 300 nautical miles of cable, and the fitting of the new machinery, was placed in the hands of the Wallsend Slipway and Engineering Company (Limited) on December 15, 1893. The new machinery is on the triple-expansion system, having cylinders 15½, 26½, and 44in. by 33in. stroke, the boilers being fitted with forced draught on Howden's system. Another Tyneside firm, viz., Messrs. Clarke, Chapman and Co. (Limited), supplied, in addition to the bow gear above mentioned, the picking-up and paying-out submarine cable gear, which is driven by compound engines of 200 I.H.P. The same firm also supplied the windlass, winches, donkey pumps, and donkey boiler, which were fitted on board the vessel. The cable gear and bow sheaves were constructed from designs supplied by Mr. P. L. Isaac, the Company's engineer-in-chief, and were made throughout of steel and phosphor bronze, so as to ensure efficiency, light weight and strength being special features. The vessel has also been fitted by Messrs. Clarke, Chapman and Co. with a complete electric light installation, including a very powerful search light projector, and electric bells and new loud-speaking telephones were fitted throughout the vessel in order to place the various parts of the ship in connection with the cable-laying operations in direct communication with each other. Amongst other adjuncts is an ice chamber to ensure the supply of fresh provisions to officers and crew when employed abroad, the machinery being supplied by Messrs. J. E. Hall and Co., of Dartford, Kent. The accommodation throughout the vessel for the officers and crew is replete with every comfort, and is noticeable for perfect ventilation to meet the requirements of the climate on the West Coast of Africa, on which this vessel will generally be engaged. The alterations have been carried out from plans received from the Eastern and South African Telegraph Company, under the personal superintendence of Mr. P. L. Isaac, assisted by Mr. Beckwith, another of the Company's engineers. At the trial a speed of about 11 knots was obtained, the machinery and its various adjuncts working perfectly throughout. The vessel sailed for London, after the trial trip, under the command of Capt. Gifford, and the Slipway Company have subsequently been gratified to receive from the Cable Company a letter expressing their entire satisfaction with the work that has been executed on the Tyne, and the expedition with which it has been carried out.

CORRESPONDENCE.

ELECTROSTATIC ERROR IN ELECTRO-MAGNETIC INSTRUMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: At the meeting of the Institution of Electrical Engineers on Thursday last Mr. Crompton suggested:—

1st. That the reason why I was able to produce such large deflections of the pointer of the voltmeter by rubbing the glass front with my pocket-handkerchief was because the glass had been dried in an exceptional way by the glow-lamp which I had placed in front of the instrument to enable its scale to be easily seen in the large lecture theatre at Great George-street.

2nd. That if the glass front were touched with the finger after being rubbed, no error on the reading of the pointer would occur.

3rd. That no deflection of the pointer would be produced if the glass were rubbed with a piece of *oily* waste (this last suggestion was made immediately after the close of the meeting).

As regards criticism No. 1, the glow-lamps in front of all the instruments were switched off at 10 p.m. Thursday evening, and all the wires disconnected. On the afternoon of the following day, however, 18 hours after the glow-lamps had been turned off, and after the voltmeter had been carried back to my laboratory, a touch on the glass with my pockethandkerchief deflected the pointer at once from 0 to 120 volts, where it stayed for some time, neither the glass nor my handkerchief being warmed nor dried in any way. This I repeated several times.

The voltmeter was then left on a table in a *north* room at the Central Technical College, no part of this building having been artificially warmed since April 6th. To-day, April 18th, after four days of rain, I again rubbed the glass cover with my pocket-handkerchief, which, like the glass, was neither warmed nor dried. It did not require much rubbing to deflect the pointer from 0 to 100 volts, where it stayed until I de-electrified the glass.

As regards criticism No. 2, it is correct that, if you know what is the position at which the pointer of the voltmeter ought to stand, it is possible, by judiciously dabbing the glass with the finger, after rubbing, to bring the pointer to its correct position; but if you do not know what is the true unelectrified position of the pointer, it is quite possible to leave it in a wrong position in spite of the glass being touched with the hand. Indeed, the engineer in charge of one of the principal London central stations wrote to me the other day:—"I find that earthing the glass with the fingers *after* rubbing, produced more marked effects than rubbing only."

As regards criticism No. 3, Mr. Mather and I dipped a piece of ordinary engine-room waste into oil and rubbed the glass cover of the voltmeter—the pointer at once went from 0 to the other end of the scale, where it stayed. Continued rubbing with the waste appeared to de-electrify the glass, but, on dipping the waste again into the oil, and smearing it on the glass, the pointer was again deflected *exactly* as if the glass were quite clean. Neither the glass, oil, nor waste were warmed or dried.

This idea that a layer of oil prevents glass from being electrified when rubbed is a common mistake, and is one that I was myself under until a few years ago. And I did not realise that it was a mistake until I saw Mrs. Ayrton experimenting on the action produced by light on the shape of electrified drops of oil. During these experiments she frequently dipped a stick of sealing-wax into oil and rubbed it with an oily piece of flannel, and she noticed incidentally that the sealing-wax was in this way as easily, if not more easily, electrified, than it was when it and the flannel were quite clean.

I think, however, that it may be quite possible to accidentally bring glass into a condition such that it cannot temporarily be electrified, for on first rubbing a glass rod with a piece of silk, it is not unusual to find the glass *negatively* electrified, the charge becoming reversed on continued rubbing. Hence, there

Digitized by Google

may be an intermediate condition of the glass and silk when no electrification is produced. And our experiments made with the oily waste appear to show that with a certain thickness of the layer of oil on the glass it is in this intermediate condition. A voltmeter, however, ought to indicate, without doubt, the true pressure between the mains, and the dynamo attendant ought not to have first to divine it in some way, and then do enough rubbing of the glass cover with his oily waste to make the instrument indicate it.

In bringing the matter before the Institution we assumed, from the remarks that central station engineers have made to Mr. Mather and myself during the past four years, that this electrostatic source of error was recognised by them, and had been, at any rate, one of the reasons why certain types of voltmeters on the switch-boards of central stations had come to be regarded as untrustworthy, and were, therefore, no longer used. Our object, therefore, was not to prove that this cause of error existed, but to illustrate how the inner side of the glass cover could be coated in a comparatively simple way with a transparent conducting varnish, so that whether the glass were hot or cold, wet or dry, oily or clean, no attraction of the pointer could be produced electrostatically.—Yours, &c.,

The City and Guilds Central Technical College, April 18, 1894. W. E. AYRTON.

LEGAL INTELLIGENCE.

Meux's Brewery Company and Shelfer v. City of London Electric Light Company (Limited).

The hearing of this case was resumed before Mr. Justice Kekewich on Tuesday. It will be remembered that it is an action to recover £10,000 by way of damages for injury caused to the Waterman's Arms, Bankside, by the works of the defendant Company, an injunction also being sought.

Mr. Warmington, Q.C., Mr. Badcock, and Mr. Waight appeared for the plaintiffs, and Mr. Fletcher Moulton, Q.C., Mr. Renshaw, Q.C., and Mr. Braithwaite for the defendants.

Mr. SEWELL, the surveyor examined on the former occasion, was now cross examined by Mr. Moulton. He said when he went to the defendants' premises on the 2nd inst. several machines were running, but of the four nearest the Waterman's Arms only three were working, and they appeared to be under light loads; they were running slowly, and there did not appear to be so much vibration. A Laing, Wharton and Down machine at the extreme southern end of the premises, and furthest from the plaintiff's premises, appeared to be running at full load. The load was shifted on to the other machines for the purpose of a test, and he and Prof. Kennedy went to the public house. The vibration did not seem so great then as he had found it upon some former occasions. In October a similar test was made. He was struck then with the fact that the vibration seemed less than usual, and when they returned to the works they found that the Laing, Wharton and Down machine was still running, so that the other machines had not been carrying the whole load. He expressed his surprise at this, as it had been understood that the machine referred to would have been stopped. His assistant did not upon that occasion tell him that Mr. Jackson, the engineer, said he could not change the load entirely without affecting the lighting. He thought there might have been a slight parting of the walls before the defendants' works were begun, caused by the original settling of Sir William Rose's house, which was built some years after the plaintiff's. But that had been greatly increased since by the excavations for the defendants' foundations causing a further settlement of Sir William Rose's house, which dragged the party wall with it. The effect of the vibration would be to still further accentuate the fissure. He did not consider the neighbourhood a very noisy one.

Mr. JOHN WALDRON, architect and surveyor, gave similar evidence to that of Mr. Sewell. Mr. Alfred Johnson, member of a firm of builders, and one of his workmen, stated that the cracks in the wall spoken of were not there when they carried out repairs at the Waterman's Arms in October, 1891.

Mr. HENRY F. JOEL, electrical engineer, spoke of several visits to the plaintiff's premises, and his evidence as to the vibration corroborated that of the witnesses already called. He further stated that he had timed the vibrations, and found that they corresponded with the strokes of the engines at the defendants' works. The engines there were not all running at the same speed, and to that fact he attributed the intermittent character of the vibration. The engines were vertical engines, and were not provided with any form of cushion to break the force of the stroke, and this fact made them much more likely to cause vibration. Witness was cross-examined by Mr. Moulton as to his experience of electric lighting generally and of central-station lighting in particular, and also as to his acquaintance with different kinds of engines used for electric lighting. He said he had carried out central stations for the Pilsen-Joel Company in Holborn and Cannon-street, and more recently, for his present firm, had carried out the lighting of Barnet. He was not aware that the alternators in the defendants' station were running in parallel; if they were, of course, his suggestion as to the different speeds would be wrong. He further suggested as a cause for the vibration the fact that the engine foundations were not isolated, but were connected with the walls of the building. He could see this himself, and he was also told by Prof. S. P. Thompson that there was no isolation.

Mr. WALTER LEWIS, manager to Sir W. A. Rose and Co., oil and colour merchants, stated that until recently he had occupied the house adjoining the Waterman's Arms, but the effect upon his children and himself of the defendants' works had been such that he had removed to the suburbs. There was a vibration throughout the house, and his health had been seriously affected. One of his children was frequently sick, and remained subject to the ailment until she was taken away. He would himself have been incapacitated for business had he remained in occupation of the premises.

WILLIAM LOVE, a lighterman, and other customers who had used the house for a number of years, spoke of the vibration and the cracks being intirely new developments since the defendants' works had been in operation; and when the Court adjourned, Mr. Warmington said the case for the plaintiffs' was practically concluded.

WEDNESDAY, APRIL 18TH.

When the Court resumed on Wednesday morning, the defendants' counsel, without addressing his Lordship, proceeded to call their witnesses.

Mr. DAVID COOK, manager of the company, gave evidence as to the expenditure of the Company, and stated that the Acts of Parliament regulating the supply of electric light had all been complied with. It was the intention of the Company to concentrate its lighting machinery at the Bankside station, when there would probably be three or four times the number of engines and alternators in the part of the station nearest the plaintiff's premises. Large sums were being spent in putting in machinery for the condensation of steam, which would have the effect of lessening the noise from the exhaust pipes.

Mr. CHARLES THOMSON, architect to the defendant Company, said he supervised the excavations for the defendants' works. These were carried to a depth of 27ft. below the level of Bankside, and were at a distance of 75ft. from the Waterman's Arms. With regard to the isolation of the machinery, their foundations were entirely distinct from the wall of the building, so far as the lower part was concerned, but they were connected at the top along two races, one for the condensing pipes, and the other, 9ft. deep and 3ft. wide, for the cables. When he called at the plaintiff's premises on October 16th; he thought the cracks which were pointed out to him were old, as the edges were discoloured. He noticed no difference in the size of the crack on March 2nd. The house was a very old one, and cracks had developed all along the front. The working of the engines could be distinctly heard, but there was no more noise than might be expected in such a neighbourhood where there were several factories and works. The building was 3in. out of the level, sloping towards the east.

Cross-examined by Mr. Waight, WITNESS said the engine foundations were separate from the wall, but touched it. He did not measure the cracks, judging merely from the appearance to the eye. Mr. Shelfer said the crack was about eighteen months or two years old, and first occurred when Sir William Rose's warehouse was rebuilt, after the fire.

Mr. FREDERICK HENRY JACKSON, electrical engineer, who has charge of the Company's stations, corroborated the previous witness's statement with regard to the engine foundations. They were entirely isolated from the wall except by the floor. The pioneer station for public lighting was started further away from plaintiff's premises in June, 1891. The machines nearest the plaintiff's premises were first started in February, 1893. There were two A 20 machines with engines of 450-H.P. Later in the year three A 40 machines, with engines of 900-H.P., were started. There were also two Laing, Wharton and Down machines with four engines of 350-H.P. each; these were started in October, 1893. They were all the best and most modern machines that could be got. None of the engines were ever out of gear upon any occasion when Mr. Sewell was present. Generally three, or perhaps four of the machines were running in the evenings during February and March of this year; in the morning two machines were worked. On October 27th the maximum load was 450 amperes, at half-past five; at half-past four, the time at which Mr. Sewell was at the plaintiff's premises on that day, the load was about 300 amperes. Two of the machines nearest the plaintiff's premises were running at that time. Nothing was ever done on the occasion of joint visits for the purposes of testing the vibration to cause the effect to be less; on the contrary, more machines were put on. When he went to the Waterman's Arms on February 2nd he could not feel any vibration by putting his hand on articles of furniture, leaning against walls, or sitting in chairs; but he could see the light articles of clothing shaking slightly. Upon that occasion two A 20 and two A 40 machines, and one Laing, Wharton and Down machine, were running; these were more than were necessary for the load, but were put on to try and produce greater vibration. Mr. Sewell suggested that the Laing, Wharton and Down machine should be stopped and the whole load thrown upon the other machines; but it was explained to him that that could not be done without great disturbance to the lighting in the City, and he seemed at the time to be satisfied with the explanation. On March 2nd a large party was present at the works, amongst them Mr. Harris, Sir Frederick Bramwell's partner, who, he understood, attended as an expert on behalf of Messrs. Meux; he certainly was not there on behalf of the defendant Company.

Cross-examined by Mr. Warmington: He considered that the isolation of a foundation meant that it was not connected at its base with any other foundation. There were air-spaces around the foundations of their engines. The foundations did rest upon a bed of concrete 3ft. thick,

Digitized by Google

and extended the whole length of the building, but he did not know whether it touched the walls or not. He was not sure what the effect would be if the number of engines and machines at the defendants' works were quadrupled; it would not necessarily, he thought, increase the vibration, as if the machines were run in opposition to each other, the pulsations from one set might counteract those from the other. He had never known sickness result from vibration in electric light stations.

Re-examined by Mr. Moulton: There was an air-space around the columns upon which the engines were built sufficient to enable a man to walk around them. There were substances suggested for the purpose of lessening vibration, but he knew of nothing more satisfactory than an air-space.

Prof. A. B. W. KENNEDY, examined by Mr. Moulton, said he was one of the consulting engineers of the defendant Company. The engines and dynamos at the works were properly constructed. On March 2nd he went to the plaintiff's premises about half-past five, and could detect no vibration. At that time nearly the highest load of the night would be going out, and at the request of someone on behalf of the plaintiffs the load was as much as possible thrown on to the machines nearest the Waterman's Arms. He did not know that any difference in vibration or noise would be made whether the engines were running with or without load. He had plumbed the wall at the back of the Waterman's Arms and found that it lay over to the east to the extent of 1⅝in. He measured the front of the building by means of a spirit level and found a drop of 3¼in. in the width of the premises, 26ft.

Cross-examined by Mr. Warmington: The excavations for the defendants' premises extended 20ft. below the level of the western wall of Sir William Rose's house. There were sub-strata of soft watery soil between. The withdrawal of the water from these strata would have a tendency to loosen the earth around. There were evidences of an apparently recent settlement of the western side of Sir William Rose's house. A person coming from an engine-room would be more, and not less, susceptible to vibrations.

Dr. SILVANUS P. THOMPSON, F.R.S., one of the consulting engineers of the defendant Company, said the foundations of the walls of the engine-rooms went down 10ft. deeper than the foundations of the engine beds. He was consulted as far back as 1891 by the defendant Company with special reference to the most suitable engines, and in consequence of his recommendations the present engines were employed. It was contrary to experience to say that a vertical engine vibrated more than a horizontal one. Other things being equal, he thought a horizontal engine was more likely to communicate vibrations to the soil than a vertical one. He did not attach any importance to the test with the garment on the bed as indicating vibration; in fact, he was indignant that it should be put forward as a fair test.

Cross-examined by Mr. Warmington: He had seen the crack at the plaintiff's house but once, but he should think it was an old crack which had opened within the past few months.

THURSDAY, APRIL 19TH.

On Thursday morning the cross-examination of Prof. S. P. Thompson was continued. WITNESS said the larger engines ran at the same speed as the smaller ones, but with a shorter length of stroke. The A 20 alternators revolved at twice the speed of the A 40 machines, but they kept step electrically. It was not the running of the alternators which caused vibration, but that of the steam-engines. He had seen no signs of damage to the defendant Company's own structure arising from vibration.

Mr. HOWARD CHATFIELD CLARKE, architect and surveyor, produced plans of Sir William Rose's house, showing the manner in which the settlement of the building had taken place. He stated that on the occasion of his visit to the Waterman's Arms, on February 2nd, he was unable to detect the slightest vibration downstairs, but in one of the upper rooms he did feel a slight trembling, but it was certainly not sufficient to cause structural damage to the building, or to interfere with the occupation or rest of persons living or sleeping in the house.

Cross-examined by Mr. Warmington: He did not admit that there was vibration in the house. There was an intermittent tremour of the bedsteads. When he sat in the window whilst a cart was passing, there was a distinct vibration of a much more distinct character. He did not think the excavations for the defendants' works drew water away from the ground sufficiently to cause a settlement and produce or increase the crack in the wall of the Waterman's Arms.

Several station assistants were called to prove entries in the log-book, and one of them, Mr. Dyson, stated that he visited the plaintiff's house, at the invitation of Mr. Shelfer, on the previous evening, and met Mr. Joel, Mr. Sewell, and others in the upper rooms there. He was asked to note whether he thought there was any vibration or not. When sitting in the room or leaning against the walls he could perceive no vibration, but there was apparently an intermittent quivering of articles on the bed. At a later hour, when he had other engines running, he asked to be allowed to inspect the rooms again. Mr. Shelfer first said he might do so, but afterwards sent to say that he had changed his mind.

Mr. RENSHAW, Q.C., addressing the Court for the defendants, said there was no suggestion that anything they had done was not done properly, in the best possible mode, and under their statutory powers. So far as any injury arising from subsidence was concerned, this subsidence being caused, as was alleged, by the subtraction of water, there was no ground for action at all. This was clearly shown by the judgment of Lord Chief Justice Cockburn in the case of "Popplewell v. Hodgkinson." Assuming that the subsidence was not caused in the way suggested, he contended that the plaintiffs were not entitled to damages, for it was stated and established that the building was caused to lean at the time of the building of the new warehouses eighteen years ago, and what had now been done, according to the plaintiffs' case, was to restore the building to the position it was in prior to that time. To entitle them to recover damages they must show that for 20 years preceding the action their house had been in a certain position, and had been, by the works complained of, disturbed from that position. With regard to the crack, if the allegation of subsidence and the claim based upon it failed, there only remained the assertion that it was caused by vibration. He asked his ordship to hold, on the evidence, that there was no such vibration as to cause within a few months a crack about 2in. wide. With regard to the action of Messrs. Meux, he contended that they, as reversioners, were not entitled to maintain an action at all, because the nuisance, if it were a nuisance, was a thing which could be removed at any time. Returning to the action of Shelfer, it was undoubted that there was at times some amount of noise, but not such as to be a nuisance or to cause injury to health or inconvenience. From first to last there had been a great deal of exaggeration of the plaintiffs' case. The vibration was greater in the upper part of the building and this, he thought, was evidence that it was to some extent due to the percussions of air from the steam exhaust, and this cause the defendants were spending large sums to remove by making arrangements for condensation of the steam. The granting of an injunction would have the effect of plunging the streets of the City into darkness, and he thought that, whilst the consequences of an injunction were not necessarily to be taken into account by the Court, there was no evidence of nuisance here sufficient to justify an injunction which would have such a serious result.

Mr. MOULTON, Q.C., followed upon the statutory authorities under which the Company worked. He said they depended upon both the provisional order, and also the Electric Lighting Act of 1882, for that Act ruled all provisional orders granted under it. The rights and privileges of the Act were sufficient to cover them; the order was not intended in any way to lessen the rights conferred on undertakers by the Act, nor did he claim that under the order they had any rights or privileges which entitled them to commit a nuisance beyond what the Act itself gave. The electric lighting companies were in the position that they had duties which were obligatory. Mr. Moulton proceeded to go through the Act clause by clause, and contended that nothing which they had done was more than they were authorised to do under the Act. So far as damage arising during the execution of works, he thought there was clearly an intention on the part of the Legislature that undertakers might be in a position to do things which would cause damage, for which there must be compensation.

Continuing his argument after luncheon, Mr. MOULTON contended that the Electric Lighting Company was entitled to the same immunities as were statutory water companies or statutory railway companies, and therefore no action could lie against them for annoyance caused by the working of their engines. There might be a claim for compensation for any damage done during the construction of the works; but with regard to the other points complained of, they formed part of the inconvenience that was borne by the public in return for the benefits they got.

Mr. JUSTICE KEKEWICH said, with regard to the point made on behalf of the defendants, that they were not liable to a common-law action, on the ground of nuisance, he was against them, and he did not think it was necessary that he should hear arguments on behalf of the plaintiffs on that point. He was now dealing with the question of injury caused to the building by the construction of the works. That was a question of evidence. What he was considering was, whether, assuming that there was noise or vibration existing, and found to be a result of the operations of the defendants as now conducted, the defendants were liable to action on the score of nuisance. It was urged that the defendants had done their very best to carry out their works in a proper way, and that they could not be charged with negligence. That was his view of the evidence, and had been throughout, except as regards the question of the exhaust-pipe. Upon that some complaint had arisen upon that, but with regard to that the defendants had not only shown that they had done everything reasonable to abate the nuisance thereby occasioned, but that they had in process of construction works which would abate the nuisance arising from that cause, and he should not in any case do more upon that point than give some nominal damages. But he was not now dealing with that point. The point was, assuming that either from this exhaust-pipe or by the vibration caused by the engines in work, there was a nuisance, were the defendants liable in common law? In his opinion there was nothing to take them out of the common law or to the liability to an action for nuisance. There was this section in the Provisional Order: "Nothing in this Order shall exonerate the undertakers from any indictment or action or any other proceedings for nuisance in the event of any nuisance being caused by them." It might be said that what the defendants were doing, and what was complained of, did not come within the Order, but came within the Act of Parliament. Was there anything in that Act which relieved the Company from liability for nuisance? The general law was perfectly plain. Power to do a particular thing, for instance, to construct a railway, did not justify the undertakers so to do that thing as to commit a nuisance, unless by express language or by necessary implication that must be inferred. Having referred to the case of the National Telephone Company v. Graf-Baker, which came before him, and also the case of the City and South London Electric Railway and others, his Lordship examined the Electric Lighting Act of 1882, and said there was nothing therein which could relieve the defendants of the liability to an action for nuisance; the Act did not say in so many words that they might or should do a particular thing, notwithstanding that in so doing they created a nuisance to their neighbours, nor did he see that there was the slightest ground for saying that there was a necessary implication. It was quite sufficient (the learned Judge thought) to base his opinion on the view, that unless they found express relief from the ordinary liability of the subject, whether a company or an individual, to an action at common law for nuisance that liability remained. He, therefore, held that the Company were not entitled to exempt themselves from an action for nuisance

Digitized by Google

in working their engines and electrical appliances. He would hear plaintiffs' counsel on the rest of the case.

Mr. WARMINGTON, Q.C., confined himself to the contention that distinct and appreciable discomfort and injury had been sustained, that the defendant company had caused that discomfort and injury, and that Messrs. Meux had a right of action.

Mr. JUSTICE KEKEWICH, in giving judgment, held that the nuisance arising from noise and vibration in the case of Shelfer had been proved, and he was entitled to damages, but not to an injunction, and the damages must take the form of compensation for disturbance. He was also entitled to damages on account of the injury to the structure. Messrs. Meux had no right of action for an injunction in their position as reversioners, but they were entitled to damages, though probably small damages, for injury to the structure. The amount of the damages in each case must be the subject of inquiry. The action for injunction in the case of Messrs. Meux would be dismissed with costs, but they were entitled to costs in the action for damages. The plaintiff Shelfer had practically succeeded in his action, and was entitled to costs.

Ebbsmith v. Dawson and Others.

In the Queen's Bench Division, before the Lord Chief Justice and a Special Jury, an action has been heard, in which Mr. Joseph Ebbsmith, of 86, St. James's street, London, S.W., sued the defendants to recover damages for alleged libel. The defendants admitted publication, and pleaded that the words used were not libellous, and did not constitute a libel on the plaintiff. Further, they said that in their ordinary signification the words were true in substance, and a plea of privilege was set up.

Sir E. CLARKE, Q.C., in opening the case for the plaintiff, said the libel complained of was contained in a passage in a circular issued by the defendants, who had constituted themselves a shareholders' committee of the South Staffordshire Tramways Company. In this circular they professed to give the past history of the Company, and one paragraph was as follows :—" Whilst the shareholders were gradually being educated up to the idea of electric traction, and their authority obtained for the necessary Parliamentary measures, arrangements were being made in another quarter, apparently with the object of turning the result to good account, as on May 29, 1889, a company was registered in London, under the title of the Electric Construction Corporation (Limited), in which Mr. Joseph Smith [the plaintiff] appears as a managing director with a holding of £4,260, as against £200 in your Company ; and Mr. George Rose (Mr. Smith's former partner) as the registered holder of £20,000, as against the two shares held in your Company ; and your Chairman, Mr. Carruthers Wain and his wife, appear to have been interested as holders of £3,120, as against a total interest of £500 each in your Company. We find that Mr. Joseph Smith occupied the position of Managing Director until 1892, from the commencement of which his name ceased to be put forward in the report of the Corporation ; and it is curious to observe that the names of Mr. Jabez Spencer Balfour and Mr. Henry Granville Wright, of Liberator notoriety, disappeared from the Directorate at the same time ; and for some reason, which we have not at present discovered, Mr. Smith changed his name at the end of 1891, by adding the prefix Ebb, so that he is no longer Smith but Ebbsmith." Counsel stated that Mr. Ebbsmith changed his name, not at the end of 1891, but in the year 1890, by the regular process of royal license, and for family reasons, and it was not true that his name disappeared from the Directorate of the Electric Corporation at the same time as that of Jabez Balfour and Granville Wright. At the time he left the Directorate of the Corporation he had no reason to distrust either Mr. Balfour or Mr. Wright.

Mr. JOSEPH EBBSMITH said he was formerly a solicitor, but retired in 1889. He had formerly been Town Clerk of Wednesbury, but resigned in January, 1889. There was no truth in the suggestion that he had utilised the larger interest which he had in the Electric Corporation to the prejudice of the South Staffordshire Tramways Company, of which he was formerly solicitor. On August 10, 1891, he resigned his position as Managing Director of the Electric Construction Corporation, and was appointed an ordinary Director in the place of Sir Robert Fowler ; afterwards he resigned his ordinary Directorship. His resignation had nothing to do with Mr. Balfour or Mr. Wright. Just before she died, his mother, who belonged to an old family of which she was the last representative, requested him to prefix her maiden name to his own name of Smith. This he did by royal license.

On Thursday, while the plaintiff was continuing his evidence, Mr. MURPHY, Q.C., for the defence, said he was happy to say that the jury would not be troubled with the case any further. The whole of the circular had not been before his Lordship, and if it had been, it would have been found that its object was to show the exact condition of things in connection with the Company. Towards the end of the circular words were, however, introduced which Mr. Ebbsmith thought reflected upon him ; but having heard the statement of Sir E. Clarke, and having seen and heard Mr. Ebbsmith in the witness-box, the defendants desired him to say that whilst entirely reserving their right to comment on the conduct of their own Directors, and Mr. Ebbsmith, so long as he was their solicitor, they did not intend to convey that Mr. Ebbsmith's withdrawal from the Company or his change of name had anything to do with the determination of Balfour and Wright's connection with it, and they expressed regret if the words used in the circular had led to that impression. They accepted the statement of the plaintiff in the witness-box that he had changed his name for family reasons, and that the Electric Construction Company in no way resembled the other companies with which Mr. Balfour had been notoriously connected. They thought the Tramway Company had entered into a contract which they ought not to have entered into, but there was no cause of complaint with regard to that against Mr. Ebbsmith. He suggested that there should be a *stet processus*.

Sir E. CLARKE said the course proposed to be taken would be a satisfactory one to Mr. Ebbsmith. Mr. Murphy was, of course, entitled to say that his clients reserved the right to say that a certain contract, which had nothing to do with plaintiff, should not have been entered into, but he (Sir E. Clarke) should have been able to show that the Electric Corporation was a strong and sound one. The plaintiff, after the statement of Mr. Murphy, was glad to end the whole case.

The LORD CHIEF JUSTICE expressed approval, and a *stet processus* was issued.

Claim against a Trades Union Treasurer.

Edward Stallard, 6, Digby-street, was summoned at Bristol before Messrs. Robinson and Low, as treasurer of the Bristol branch of the Electrical Trades Union, for withholding £9. 10s. 4d. belonging to the organisation, the complainant being Mr. Walker, General Secretary of the Union.

The proceedings were taken under Section 20 of the Friendly Society Act, 1875, and the case had been before the Court on two previous occasions. It was stated in evidence that the branch was started in 1893, but was closed by order of the Council at the head office in London for refusing to comply with orders. All the members were in arrear, and there was none eligible for office. Defendant was appointed treasurer on January 12, 1894, and, according to the books, had a sum of £9. 10s. 4d. in hand, which he had from the out-going treasurer, to whom he gave a receipts.

For the defence it was stated that the members intended appealing against the decision of the council closing the branch, and by resolution had authorised the defendant to retain the money pending further inquiries. Stallard admitted having £8. 17s. 4d. in hand.

Several points of law were raised on behalf of the defence, one being that as the organisation was not registered under the Friendly Society Act the summons could not succeed.

Mr. ROBINSON said the magistrates were of opinion that they had no power to make an order under the Friendly Society Act, and they therefore dismissed the complaint, and awarded the defendant £1. 4s. 6d. costs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Committee of Visitors of the Devon County Asylum, Exminster, invite tenders from makers of electric light wires, casings, fittings and various supplies, the Committee having decided to carry out the wiring of the asylum by their own staff. Further particulars are given in our advertisement column ; and samples and prices of the materials should be sent in to Mr. Arthur E. Ward, Clerk to the Committee, 9, Bedford-circus, Exeter, not later than May 15th.

———— Tenders for the supply and erection of Willans engines, continuous-current dynamos, pipe work, spare armatures, &c., for the Council of the Borough of Brighton, have to be in by 10 a.m. on the 30th inst., to Mr. F. J. Tillstone, the town clerk, Town Hall, Brighton.

———— The tenders invited by the Southampton Harbour Board for the work comprised in the lighting by electricity of the Town Quay, Southampton, have to be sent in to Mr. A. H. Skelton, the Harbour Board Offices, Town Quay, Southampton, by May 8th.

———— The St. Pancras Vestry invite tenders for the buildings to contain the electric lighting plant at King's-road, Camden Town, N.W. The drawings can be inspected, and other information obtained, at the offices of Prof. H. Robinson, C.E., 13, Victoria-street, S.W. ; and tenders must be sent in to Mr. Albert E. Pycraft, chief clerk, Electricity and Public Lighting Department, Vestry Hall, Pancras-road, N.W., not later than noon on Monday, May 7th. Other particulars are given in our advertisement columns.

———— The tenders for working the tramways throughout the City of Leeds, which are invited by the Corporation, have to be in by May 5th. All particulars can be obtained of Mr. J. Harrison, town clerk, Town Hall, Leeds.

TENDERS ACCEPTED.—The Shropshire Electric Light and Power Company (Limited) have accepted the tender of Messrs. Edmundsons (Limited) for supplying and erecting the plant and apparatus for the electric light installation for Shrewsbury, including buildings, engines, dynamos, mains, cables, &c.

———— The tender of Messrs. S. H. Heywood, of Manchester, has been accepted for the supply of electric light fittings, switchboards, lamps, wiring, &c., for lighting the technical school now in course of construction at Broad-street, Bury, Lancs., for the Bury Corporation.

———— The Vestry of St. Pancras have accepted the tender of Messrs. Easton, Anderson and Goolden (Limited) for the supply of boilers for the electricity station at King's-road, for the sum of

Digitized by Google

£2,837. 6s. 2d. The tender of Messrs. Doulton and Co. for water-softening apparatus for the same station, for the sum of £198, has also been accepted.

APPOINTMENT.—Mr. V. A. H. McCowen, of Tralee, has been appointed resident electrical engineer to the Belfast Corporation, at a salary of £250.

APPOINTMENTS VACANT.—The Technical Education Committee of the Portsmouth Corporation invite applications for the appointment of Principal of the Municipal Technical School. The Principal must devote his whole time to the work of the school, and to advise the Committee in reference to the appointment of assistant teachers. The stipend for the first year will be £250, and £300 per annum afterwards. Applications must be sent to Mr. Alex. Hellard, Town Clerk, not later than 10 a.m. on May 9th. Further particulars appear in our advertisement columns.

TRADES UNIONISM AND CENTRAL STATION PUPILS.—On Thursday evening last week a deputation of the Portsmouth Branch of the Amalgamated Society of Engineers waited upon the Chairman and Vice-Chairman of the Electric Lighting Committee of the Portsmouth Corporation, to complain that the remuneration offered to the mechanical engineers engaged for the electric lighting works was considerably below the current rate of wages, and was opposed to the resolution adopted by the Corporation. After hearing the views of the deputation, Alderman Ellis explained that the officials referred to were not mechanical engineers at all, but assistant superintendents. They probably had some knowledge of mechanical work, but were by no means trained to the use of tools like fitters, who have served an apprenticeship to their trade. Nor were they required to do the work of a fitter. They would have to deal with no fewer than thirteen dials and work out mathematical calculations, in order that the power might be properly given according to the varying requirements of the consumers. The Board of Trade insisted that scientific men should be employed upon such important duties, and he would not for a moment hold himself responsible for what might occur in the event of the work being placed in the hands of men who had not received that scientific education which could alone ensure their fitness for the work. The President of the Amalgamated Society replied that his Society did not recognise them as electrical engineers, because, in the opinion of the members, they were being drafted into certain positions with the object of robbing them of the work which should belong to their trade alone. Two of the deputation were electricians who could design, construct, and work the whole of the Committee's machinery. The men appointed might be able to make mathematical calculations, but the moment anything went wrong with the plant they would be compelled to fly to mechanics for the execution of the repairs. Was it right or just that men who could not be relied upon to set matters straight in case of emergency should be employed on work which properly belonged to fitters? Alderman Foster said the officials did not come under the rules of the Amalgamated Society. They had served as students, and now took positions at nominal salaries to gain experience and qualify for superior appointments. They were not mechanics but professional men. Alderman Ellis said the interview would be reported to the Committee, and no doubt the representations of the Amalgamated Society would receive every consideration so long as they were confined to men belonging to the Society.

SHOP AND WORKROOM LIGHTING.—The handsome premises just erected by Messrs. Redfern in Conduit-street, London, W., have been lighted throughout by electricity; and some considerable extensions to Messrs. Marshall and Snelgrove's huge block in Oxford-street have also had the electric light extended to all departments.

THE LIGHTING OF STAIRCASES.—The demolition of large numbers of dwellings until lately occupied by the poor in London has led to the erection of a considerable number of large blocks of "model" buildings, let out in tenements, and a Select Committee of the House of Commons has before it an Omnibus Bill promoted by the London County Council, one of the chief provisions of which is to fix upon the owners of these model dwellings the obligation to light the staircases from sunrise to sunset.

PUMPING MACHINERY.—A trial was recently made at the Newcastle works of Messrs. Ernest Scott and Mountain of two sets of large-size electrically-driven pumps now in course of construction for the Lothian Coal Company. The trial proved successful. The plant is probably the largest pumping plant electrically driven ever put down for colliery use, the electrical plant consisting of two "Tyne" dynamos, equal to an output of 60,000 watts at 600 revolutions; two 60-H P. electric motors; two sets of three-throw pumps capable of delivering 200 gallons per minute against a head of 650ft.; two 150-E.H.P. horizontal engines; conducting cables, &c.

STATION INDICATORS.—A demonstration of an automatic station indicator was given at Ealing recently, the object of the device being to indicate to passengers in the trains running on the Metropolitan and Metropolitan District systems the next station at which the train will arrive.

PROFIT SHARING.—The Newcastle-upon-Tyne Electric Supply Company (Limited) has a profit-sharing arrangement with its employés, and, under the system adopted by the Company, 27 shares have been appropriated for the benefit of W. McArthur, engine driver, and 25 shares for T. Purves, stoker.

ELECTRIC CONSTRUCTION COMPANY.—This Company has obtained the order for the electric plant for Stafford, and has secured the contract from the County of London and Brush Provincial Electric Lighting Company, for the lighting of the united parishes of St. James and St. John, Clerkenwell. These are in addition to the contracts for Wolverhampton, Halifax, and Aberdeen, which the Company has in hand. They are also busy with the equipment of the Madras electric tramways. An advance has just taken place in the price of the Electric Construction Company's shares. As already announced, Mr. A. B. Blackburn, M.I.C.E., late with Messrs. Mather and Platt (Limited), has been appointed chief engineer to the Company. Mr. Thomas Parker, the founder of the firm of Elwell-Parker, now known as the Electric Construction Company, severed his connection with the Company last week, and five members of the technical staff, most of whom had served the firm of Elwell-Parker, have, we learn, resigned with their late chief.

EDISON AND SWAN FITTINGS.—A very handy hanging sheet of plain and ornamental electric light fittings is issued by the Edison-Swan Company, and the trade can obtain copies on application. Illustrations are given of special new designs of electroliers, standards, brackets, pendants, hanging lamps, portable lamps, and ceiling fixtures, made in black bronze, polished brass, hammered copper, nickel-plated silver, or hammered iron.

MESSRS. MIX AND GENEST.—We are asked to state that the rumour that the Mix and Genest Agency in Manchester is given up is untrue, and has no foundation. Mr. C. A. Clarke has, since the commencement of their electrical business in England some years ago, represented Messrs. Mix and Genest, and will continue to do so, at 3, Delaunays-road, Crumpsall.

MESSRS. JOHN DAVIS AND SON.—This firm send us a copy of their catalogue, just ready, giving full illustrated particulars of the various apparatus manufactured by the firm. A principle section of the catalague is devoted to mathematical drawing instruments, of which the firm make a special feature. The catalogue consists of 70 closely-printed large 4to pages.

"ADRESSBUCH DER ELEKTRISCHEN ANLAGEN."—We have received a copy of this directory, the first part of which contains lists of the names of proprietors of electric light installations in Germany, Austria, Denmark, Great Britain, Italy, Netherlands, Norway, Russia, Sweden, and Switzerland, arranged alphabetically under the various cities and towns. If the Continental lists are better than the British, about which it were the kinder course to say nothing, the book may be of use to makers of electrical instruments, apparatus, lamps, &c. The concluding section of the book gives lists, similarly arranged, of German electrical firms.

SILVERTOWN CARBONS.—The India Rubber Company have just issued a revised list (No. 34) of Gray's patent carbons for electric lighting, for which it is claimed that they are stronger and more homogeneous than ordinary carbons, and, from the care used in their manufacture and the regularity of their composition, the points remain perfectly shaped while burning.

PATENT OFFICE LIBRARY.—This office is open free from 10 a.m. to 10 p.m. every week day, and contains English, Colonial, and foreign specifications and trade marks, text books, periodicals, &c., in all branches of science, English and foreign. The number of readers for the week ending April 7th was 2,396, and for the week ending April 14th, 2,330.

ACCRINGTON.—At the meeting of the Town Council the recommendation of the Legal and Parliamentary Committee that an installation of the electric light, to supply not less than 2,000 16-c.p. incandescents, with provision for extension, came up for confirmation. The minutes were, after discussion, referred back for reconsideration.

ALLEGED THEFT OF A TELEPHONE.—At the Sheffield City Police Court, on Thursday, George Emberley was charged with stealing a telephone, the property of the National Telephone Company. It appeared that the prisoner went to a subscriber's offices on the previous Monday and asked to inspect the telephone, representing that he came from the Company. He said the instrument was bad, and he would have to bring a new one, and took the old one away. The next day the man who was really in the employ of the Company called and the fraud was discovered. The prisoner had offered the instrument for sale to Mr. J. T. Sutcliffe, electrician, Sheffield Moor. Mr. Preston, the district manager to the National

Digitized by Google

Telephone Company, stated that prisoner was not employed by them. He had obtained telephones in a similar manner before, and sold them. The prisoner was sentenced to four months' imprisonment with hard labour.

ASHTON-UNDER-LYNE.—It has been decided to refer to the General Purposes Committee the question of considering the advisability of lighting the district by electricity.

BASINGSTOKE.—The Lighting Committee of the Town Council have reported and ask permission to employ the services of an electrical engineer in reference to the lighting of the district by electricity at a fee not exceeding £21. The recommendation was adopted.

BEDFORD.—The Corporation have decided by a majority of four to carry out the provisions of their Electric Lighting Order (granted August 4, 1890) before January 1, 1895. It has been decided to appoint an electrical engineer, and the lighting scheme has been referred to the Electric Lighting Committee, with power to act.

BRADFORD.—The Gas and Electricity Committee of the Corporation have received requests from a number of the principal tradesmen outside the present electric lighting area, asking for an extension of the light, and a sub-committee has been appointed to consider the matter.

BRECHIN.—At the last meeting of the Town Council a resolution was moved that the Board of Trade be applied to for a Provisional Order, but after considerable discussion the matter was adjourned for a month, the Town Clerk in the meanwhile to make inquiries.

BRISTOL.—The Electric Lighting Committee of the Corporation have decided to purchase an engine and dynamo capable of supplying the demand for electric current during the day time, at an estimated expenditure of £613.——Mr. A. W. Ranken has resigned his appointment as Chief Assistant Engineer to the Corporation, and Mr. E. H. B. Tyler has been appointed to the position.

BUCKINGHAM.—The Town Council have been informed by the local gas company that unless the company be allowed to light all the street lamps with gas they will not undertake to light any. It has been decided to invite the Electric Lighting Company and the Gas Company to send in tenders for lighting the street lamps, excluding those already lighted by contract by the former.

BUXTON.—A long discussion took place at the last meeting of the Local Board on the question of the electric lighting of the town. No definite decision having been come to, it was ultimately decided that a special meeting should be held to consider the question.

CHURCH LIGHTING.—St. John the Baptist Church, Broad-street, Bristol, is now entirely lighted by electricity, the massive gas brackets, which formerly interrupted the view of the seatholders, having been removed. It is generally agreed that the change from gas to electricity is a great improvement.

CITY OF LONDON.—The Court of Common Council have decided to extend the electric light at the Guildhall to the Art Gallery at an estimated cost of £290, inclusive of fittings.

CLERKENWELL.—The County of London and Brush Provincial Company has notified to the Clerkenwell Vestry that work is about to be commenced for lighting the district by electricity so as to be in time for the coming winter demand. The whole of the 19,900 shares of £10 each, recently offered for subscription, are, it is stated, now subscribed and allotted. The order for the plant is, as stated elsewhere, in the hands of the Electric Construction Company.

DERRY.—The Local Government Board has agreed to grant to the Derry Corporation a further loan of £2,871 in excess of the original amount to enable the Corporation to complete the scheme for 160 arc lamps, the payment to be spread over a period of 25 years. A further sum asked for by the Corporation will probably also be granted.

DUBLIN.—Mr. Robinson, in presenting the report of the Electric Lighting Committee to the Corporation, showing the expenditure and receipts for the year 1893, said that the city accountant had informed him that if the Corporation were a private company they would be in a position to pay a dividend of 4½ per cent. upon their electric lighting undertaking.

EXHIBITION.—The Exhibition to be held in Bordeaux in 1895 is to be universal so far as regards exhibitors of wines and spirits, and of electrical plant and apparatus. The general, industrial, and agricultural portion of the Exhibition is to be open only to exhibitors from France and French possessions, from the United Kingdom, Belgium, Switzerland, Italy, Spain, and Portugal, but not from Germany!

EDINBURGH.—An important deputation has waited upon the Town Council to ask for a considerable extension of the electric lighting scheme, and after consultation with that body it has been decided to refer the matter to the Electric Lighting Committee for immediate attention.

HAMPSTEAD.—The Electric Lighting Committee of the Hampstead Vestry have reported that they hope to be in a position to supply the electric light in their compulsory area early in July next. At the last meeting of the Vestry a resolution was carried that application be made to the London County Council for permission to borrow a further £25,000 for the purposes of the electric lighting scheme.

HOTEL LIGHTING.—Mr. Matthew Buchan, of Portobello, has recently completed the lighting by electricity of the Grand Restaurant, Edinburgh.

KENSINGTON.—The Vestry have informed the Notting Hill Electric Lighting Company that they are prepared to consider any proposal the Company may make for dealing with an area larger in extent than that for which the Vestry's permission has recently been applied for to lay mains outside the area specified by the Company's Provisional Order. At the same time permission has been granted for certain extensions asked for by the Company.

LANCASTER.—The Corporation have notified intending consumers of electric current that continuous supply was commenced on the 17th inst.

LEITH.—The Leith Dock Commissioners have decided to proceed with the electric lighting of the old dock and the Victoria Dock at once, and the lighting of the Edinburgh Dock will be afterwards promptly proceeded with.

LIGHTING CONTRACTS.—Messrs. Baxendale and Co. send us a list of lighting contracts recently secured in the Manchester and Oldham districts.

MIDSOMER NORTON.—The Island Flour Mill at this place has recently been opened, and has been fitted throughout for the electric light, under the engineering superintendence of Mr. Charles H. Shearn.

MONTROSE.—A special meeting of the Police Commission was held on Thursday, when a lengthy report was submitted from the deputation appointed to make inquiries respecting the proposed introduction of the electric light into the burgh. The report stated that the Coatbridge station was that which the deputation suggested should be taken for the model for that at Montrose. It was ultimately decided that a deputation consisting of the whole Board should visit Coatbridge and inspect the installation.

NEWCASTLE.—The local gas company have notified the City Council that they have power, under their Act of Parliament, to charge for all public lamps, whether in use or not; and should the Council decide upon introducing electric lighting, the Company were determined to charge for any gas lamps which, in consequence, were extinguished. The Watch Committee of the Council have decided to contest this remarkable claim of the Company should they act as indicated.

NEWPORT (MON.).—At the meeting of the Town Council on Tuesday the various tenders accepted by the Electric Lighting Sub-Committee were finally agreed to, with some minor variations. An amended plan for the proposed electric lighting station was submitted, which would allow of a better arrangement of the plant, the area and the cost being slightly reduced, and making it possible to use Lancashire boilers instead of tubular.

SHEFFIELD.—It is stated that the new capital issued by the Sheffield Electric Light and Power Company (Limited) has been subscribed, and that letters of allotment are to be sent out immediately.

STAFFORD.—The Electric Lighting Committee of the Town Council have recommended that the following tenders be accepted:—For engines, Messrs. Robey, £2,288; boilers, Hick, Hargreaves and Co.; dynamos, the Electric Construction Company, £1,151; buildings, J. Lovatt, £3,030; ironworks and roofs, Rubery and Co., £197. Alderman Peach, in proposing the adoption of the Committee's report, said that owing to some misunderstanding about the tender of Messrs. Robey for the engines it would be necessary to refer the report back to the Committee.

STIRLING.—The Town Council on Monday resolved to instruct the Electric Light Committee to obtain all necessary information in view of the Council applying for a Provisional Order in November.

WINDSOR.—In reply to a question as to when the Electric Lighting Committee of the Urban Sanitary Authority would present their report, it was announced that communications had been received by the Committee, the nature of which it would be unwise to make public at present. A petition is in course of signature throughout the town to the Town Council, urging upon that body to take immediate steps to provide the town with electric light. Already a large number of influential signatures have been obtained.

YORK.—The Lord Mayor of York and the Electric Lighting Committee of the Corporation have visited Oxford for the purpose of inspecting the system adopted by the Oxford Electric Lighting Company. The party subsequently visited the Wolverhampton works of the Electric Construction Company.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

March 20, 1894.

5,728. W. ROUTLEDGE. Newcastle-on-Tyne. Adapting electro-motors to dental purposes.

5,735. E. J. PATERSON and C. W. HILL. London. Improvements in electrical switchboards.

5,754. W. H. LANDER. Dublin. An improvement in electrical arc lamps.

5,796. H. A. F. PETERSEN. London. Improvements in underground conduit systems for electric railways.*

5,806. A. S. BAXENDALE. London. An improvement in dynamo-electric machines and apparatus for driving them.

5,807. THE EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED) and C. F. PROCTOR. London. A duplex electric safety fuse.*

5,816. H. H. LAKE. London. Improvements in electrical measuring instruments. (E. Weston, United States.)*

March 21, 1894.

5,863. H. REASON. Brighton. Improvements in fuse boxes for electricity supply mains.

5,913. J. S. RAWORTH. London. Improvements in alternators.

5,917. Sir C. S. FORBES, Bart. London. Improvements in and relating to telephone and telegraph systems.

5,918. S. S. ALLIN and W. H. WOOD. London. Improvements in arc lamps.

5,921. Sir C. S. FORBES, Bart., and THE DOMESTIC TELEPHONE COMPANY (LIMITED). London. An improved telephone combination.

5922. A. HOWARD. London. An improved automatic electric machine.

5,931. E. J. CLUBBE and A. W. SOUTHEY. London. Improvements in electrically propelled common road vehicles.

5,932. E. J. CLUBBE and A. W. SOUTHEY. London. An improvement in electrically-propelled vehicles.

March 22, 1894.

5,971. A. G. ADAMSON. Glasgow. Improvements in apparatus for the use of the electric light for photographic purposes.*

6,028. S. JEVONS. London. An improvement or improvements in electro-dynamo machines and in electromotors.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d. each.

1892.

23,101. SCHROEDER, C. A. J. H. and H. E. R. Galvanic batteries.

1893.

2,740. RATHBONE. Electric arc lamps.

4,685. BOTT. Recording and reproducing tapes for electrical ticker machines, &c.

4,874. FOSTER. Transforming, &c. electric currents.

5,198. HARGREAVES and BIRD. Electrolytic apparatus.

6,004. SUDDARD. Type-writers and printing telegraphs.

6,170. HOLLINS and MEIR. Earthenware electric switches, &c.

6,205. WOOD. Distributing electricity for lighting, &c.

6,684. MÜLLER and ADKINS. Gas, electric, &c., lamps.

7,082. KETKY. Brackets for electric lighting, &c.

7,266. WHITCHER. Distributing electric energy.

7,594. LYTE. Electrolytical decomposition of chlorides.

7,713. JOHNSON. Gland joint for electric conductors.

8,316. NEW and MAYNE. Electrical propulsion of boats and vessels.

8,571. EMERY. Cells for electric batteries.

8,812. ABEL (Soc. Générale des Telephones Reseaux Telephoniques et Constructions Électriques). Telephone indicators.

1894.

666. EVANS. Holders for incandescent lamps.

2,007. EDISON and SWAN UNITED ELECTRIC LIGHT COMPANY, and PROCTOR. Electric switch.

2,203. DURLACHER and OTHERS. Electric candle lamps.

2,514. WEST. Electric bells.

2,562. ASHLEY. Electric tramways and railways.

2,812. TESLA. Generating electric currents.

2,900. RUDHOLZNER. Electro-deposition of metals.

3,020. TUDSBURY. Induction electrical machines.

3,223. DONALDSON. Heating gases by electricity.

3,384. TURNBULL. Electric lamps.

COMPANIES' MEETINGS AND REPORTS.

Eastern Extension, Australasia, and China Telegraph Company (Limited).

Sir John Pender, G.C.M.G., M.P., presided on Wednesday at Winchester House, 50, Old Broad-street, over the forty-first ordinary general meeting of this Company.

The SECRETARY (Mr. F. E. Hesse) having read the notice calling the meeting and the minutes of the previous meeting, which were confirmed, the report of the Directors was taken as read.

The CHAIRMAN then said: Gentlemen, I have always at these half-yearly meetings gone over in detail some of the figures of the report, and as I think that the practice has been generally acceptable to the shareholders, I will continue it to-day. The gross receipts for the half-year under review have amounted to £251,000, against £247,000 for the corresponding period of 1892, showing an increase of £4,000. The working expenses have amounted to £76,000, against £91,000 for the corresponding period of 1892, showing a decrease of £15,000, which is entirely accounted for by the repairs to cables having cost only £21,000 during the past half-year, against £38,000 in the corresponding half-year of 1892. (Applause.) Comparing the figures for the whole year the results are as follows: The gross receipts for 1893 were £509,000, against £494,000 in 1892, or an increase of £15,000. The working expenses for 1893 were £155,000, against £171 000 in 1892, or a decrease of £16,000. The net revenue for 1893 was £282,000, against £250,000 in 1892, or an increase of £32,000 (cheers), half of which is due, as already explained, to the reduction in expenditure for cable repairs, and the other half to increased revenue resulting from the raising of the Australian tariff, which was done at the request of the Colonies, from 4s. to 4s. 9d. per word, and to the exceptionally heavy Australian traffic transmitted during the financial crisis last summer in connection with the numerous Bank failures and reconstruction schemes. But for this there would have been a considerable falling-off in revenue, as the working of the Australian Tariff arrangement for the third year of "guarantee" ending this month shows a loss estimated at between £11,000 and £12,000 notwithstanding these exceptional causes.

We have also experienced a further heavy loss on exchange during the past year, through the continued depreciation of the silver currency, although when we raised the rates of collection at the currency stations a year ago we thought we had fully protected the Company by the rates then fixed. The depreciation, however, has been far greater than was anticipated, and as there appears to be no prospect of any permanent substantial recovery, your Directors have reluctantly decided to further raise the rates, where they are free to do so, from May 1st next, so as to give the Company the equivalent of their sterling charges. (Hear, hear.)

The usual interim dividends have been distributed during the past year, making, with the dividend proposed to be paid to-morrow, a total payment of 5 per cent. for 1893. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the past year. (Applause.)

The balance of £107,830 has been carried to the general reserve fund, which now stands at £633,686, made up as follows:—Amount of reserve at end of 1892 £509,733, interest credited during 1893 £14,114, value of cable recovered after renewals to Hong Kong-Saigon and Madras-Penang sections £2,009, balance from revenue account (1893) £107,830, leaving the fund, as already stated, £633,686, after having expended £1,160,685 out of reserve on cable renewals, duplications and triplications since the formation of the Company, and thus greatly strengthened and improved the market value of your property. (Cheers.)

In terms of the trust deed a further drawing by lot of 371 of the Company's Five per Cent. Australian Subsidy Debentures took place on the 2nd instant, for payment at par on July 2nd next, when the Debenture Debt, which originally stood at £640,000, will be reduced to £248,400.

At the last general meeting I referred to the arrangements which we had entered into with Her Majesty's Government and the British North Borneo Company for bringing Labuan and North Borneo into telegraphic communication with Singapore, Hong Kong, and the rest of the world, and at the same time strengthen our China system by securing an alternative line between Singapore and Hong Kong. Since then we have had the cable manufactured and sent out, and the first section, viz., that between Singapore and Labuan, was last week completed and opened for traffic. The remaining section, from Labuan to Hong Kong, will be laid during the present month. The length of the new cable is nearly 2,100 nautical miles, costing about £300,000, and it will increase the total mileage of our system to a little over 18,000 miles.

For some time past we have been endeavouring to strengthen the service between Singapore and Banjoewangie, the station at the east end of Java where the three Australian cables are landed, without incurring the heavy expense which the duplication of the Singapore-Banjoewangie cable would involve. With this object negotiations were entered into with the authorities at the Hague and in Netherlands-India, with the satisfactory result that we have secured a special wire on the Government land-line through Java for the transmission of the international traffic by our own employés. This special wire gives us an efficient alternative communication to our Singapore-Banjoewangie cable, and consequently renders it unnecessary, at all events for the present, to duplicate this section. A small station has been opened by the Company at Sourabaya in connection with the new line, and we have been much gratified to learn that the telegraphing public in Java are greatly pleased at the marked improvement in the international service which this arrangement has effected. (Applause.)

Digitized by Google

You will have observed from the newspapers that the agitation for a Pacific cable between Canada and Australasia has of late greatly increased, and that at the Postal and Telegraph Conference recently held at Wellington a resolution was passed recommending the Governments interested to offer any company willing to lay the cable a guarantee for fourteen years of 4 per cent. on a capital not exceeding £1,800,000, on condition that the tariffs are reduced to 3s. per word for ordinary telegrams, 2s. per word for Government telegrams, and 1s. 6d. per word for press telegrams. A deputation of Australasian and Canadian Government representatives has since waited upon Lord Rosebery and Lord Ripon at the Colonial Office to urge the Imperial Government to take part in the movement, and Lord Rosebery has announced that the Government will send a representative to the Conference to be held at Ottawa in June next for further considering the question, in order to watch the proceedings. Beyond this, however, the Imperial Government does not appear to have committed itself either one way or the other. This agitation, however, is almost entirely based on sentiment, an "all British cable," as its advocates are pleased to style it, having less chance of immunity from interruption in time of war than the existing cables which follow the principal trade routes, and could therefore be more easily protected. Moreover, it is a moot point whether a cable, if once broken, could be picked up from such great depths as are reported to exist in the Pacific Ocean. But apart from this, a Pacific cable is not wanted to meet commercial requirements, the existing service to Australia being acknowledged to be one of the most efficient and cheapest in the world, capable of transmitting a far greater traffic than it at present carries. Consequently, to put down another line of cables on commercial grounds at a cost of nearly two millions sterling, or four millions sterling if duplicated, would be simply throwing away money, and promoting unnecessary and ruinous competition; and as the existing system was established by private enterprise, without any Governmental assistance whatsoever, Her Majesty's Government could not in equity grant pecuniary aid to the proposed competing line without subsidising or guaranteeing our cables to at least the same extent. (Hear, hear.) If, however, a Pacific cable is required for strategic purposes, which I very much doubt, and the Governments concerned are prepared to provide the necessary subsidies to enable it to be carried out, then it would be better and cheaper for them to arrange with us to do the work. By this means our special facilities and large experience in cable matters could be profitably utilised, and the line worked in connection with, instead of in opposition to, the present service, thus avoiding injury to existing interests. To show how utterly inadequate the terms proposed by the Wellington Conference are, I may mention that a Pacific cable would require no less a sum than £237,000 a year to cover its working expenses, maintenance, amortisation, and interest on capital, so that a 4 per cent. guarantee, or only £72,000, would still leave £165,000 a year to be made up by the earnings of the line; and as the value of the whole existing traffic with Australasia, if diverted to the Pacific, would only produce about £90,000 at the proposed reduced rates, there would still be a deficit of £75,000 to be made up even if the Pacific cable carried the whole traffic. These figures speak louder than words, and show clearly enough that a Pacific cable is quite impossible unless the Governments interested are prepared to give a very large subsidy towards carrying it out. (Hear, hear.)

With regard to our relations with the Foreign Governments with whom we are associated, I am happy to state that, with one solitary exception, they are all that could be desired, but in China, where the land-lines are unfortunately competing with the cables, we have not yet succeeded in bringing about the friendly working between the Telegraph Administration and the cable companies which we have so long striven for. No effort will, however, be spared to secure a good understanding with the Chinese if possible. (Hear, hear.) The remarks which I have just made respecting the Pacific cable agitation, and which I purposely read, have been very carefully thought out and put clearly and distinctly, with the object of their being read by those who are talking and thinking about this Pacific cable. For myself I am bound to say that, looking to the nature of the agitation, and to those engaged in it, and looking at the peculiar pecuniary position both of our own country and the colonies, at the present moment, I do not regard this Pacific cable with anything like fear or dread. It is not wanted, I believe, for strategic purposes, and certainly it is not wanted for commercial purposes, and I am, therefore, satisfied that the project is very far off yet from being carried into effect; and although a conference is to be held at Ottawa, it is not likely to interfere with us in the next few years. (Applause.) If, after the hard times which have been experienced in the colonies, a great period of success comes, and the colonies go on developing in the future as they have done in the past, rendering necessary another line of telegraphy, we are prepared to deal with the matter, but on such terms as would not only protect existing interests, but also give us a fair return on any money that might be placed in it, whether it is carried out by the present route, or by the Pacific. (Hear, hear.) In regard to the new cable which we are laying at great expense between Singapore and Hong Kong, I am pleased to find that even in China they approve of the principle on which we have gone, and regard the privileges which have been granted to us as fair and just. (Cheers.) I may also say that our arrangements with the Governments with whom we are associated have always been based on sound commercial principles, and, therefore, anything that is brought against us must be something very extraordinary to upset a system which has been so carefully built up, and which is admitted to have been a marked success as regards our conduct of the business and the advantages derived from it by the public. People have called it a great monopoly. It is really no monopoly at all, except in this sense—that we have done the work so well and beneficially to the general public, that it would require a bold syndicate to attempt to compete with us. (Applause.) I think I have now said enough about the Pacific cable. We continue to pay you a fair dividend—not an extravagant one, but still a large one compared with the general run of dividends—and we have made your dividend more secure and your property more valuable by the reserve fund which we have accumulated. (Cheers.) You have approved of that policy in the past, and it will be our policy in the future to still further increase our reserve fund so that we shall be made more independent if competition should arise, or if we should require additional cables. (Cheers.) I now beg to move—

"That the report and accounts of the Directors, now submitted, be received and adopted, and that a dividend be now declared of 2s. 6d. per share, together with a bonus of 4s. per share, both free of income-tax, payable on the 19th inst., making, with the previous distributions, a total payment of 7 per cent. for the year 1893."

The Marquis of TWEEDDALE seconded the motion.

The CHAIRMAN invited discussion, but no shareholder rising to address the meeting he put the resolution, which was carried unanimously. Continuing, he proposed—

"That Francis Augustus Bevan, Esq., who now retires by rotation, be and is hereby re-elected a Director of this Company."

Mr. C. W. EARLE seconded the motion, which was unanimously adopted.

The CHAIRMAN then proposed—

"That Sir Albert J. Leppoc Cappel, K.C.I.E., who now retires by rotation, be and is hereby re-elected a Director of this Company."

Mr. G. G. NICOL seconded the motion, which was unanimously adopted.

On the motion of Mr. BRADNOCK, seconded by Mr. STARNES, the following resolution was also carried:—

"That Messrs. Deloitte, Dever, Griffiths and Co. and Messrs. Welton, Jones and Co. be and they are hereby elected auditors for the ensuing year, at a remuneration of £100 each."

The CHAIRMAN: That is all the business I have to put before you to-day. You have had the accounts in your possession for some time, and I think you will have been satisfied that we are not going back, but are rather improving, and, as I have said before, the more we increase our reserve fund the stronger will our position become. (Hear, hear.)

Mr. JOHN NEWTON: Mr. Chairman, I wish to move a vote of thanks to you, not only for the pleasure it will give me to do so, but also because it will afford me an opportunity of asking you a question which I did not put on the motion for the adoption of the report, because I think that the carrying of the report without any question being asked is a compliment to the Directors. (Hear, hear.) I think that the conferences which are held from time to time by the various Governments of Europe interfere with your tariff charges, and I think that it is very unjust that we should be subjected to the interference of Governments, and even of the English Government, and that we should afterwards be attacked as we are with this continual agitation for a Pacific cable. You have shown us good reason why that cable is not wanted, although there is one reason no doubt why it is wanted, and that is for jobbery and corruption. I am sure there is something in connection with the laying of that cable which will be beneficial to those who are agitating for it, although not for those who subscribe their money to it. Have you not in past years reduced your tariffs in deference to the opinions of Governments? If so, it is rather unjust that Governments should lend any countenance to a competing cable the great object of which will be to interfere with this Company, which has rendered such immense service to the world.

Mr. BURGESS: I have very much pleasure in seconding this vote of thanks. I think we owe a very great debt of gratitude to our excellent Chairman and Board for their administration of our affairs. (Cheers.) I think we may all feel very safe in leaving them in the hands of such an able Chairman as we have, and such business men as he has to assist him on the Board. (Applause.)

The resolution was carried unanimously.

The CHAIRMAN: I am always pleased, as are my colleagues, to find that the administration commands your approval and confidence. I am vain enough to think that the success which has attended our affairs entitles us to the goodwill and commendation of the shareholders, and it is gratifying not only to find that you appreciate our work, but also that we are all, as it were, sailing in the same boat. We believe in one another, and it is that unity which gives strength. (Hear, hear.) As you probably know, I am a very strong Unionist, and I apply that principle in this particular instance. I never knew divided camps or divided interests ever lead to the same satisfactory result as a united, compact, and straight-going policy and practice. Mr. Newton has referred to the Pacific cable agitation. Where there is a large cable going to be laid and where there are people who are looking out for contracts, you never can be other than suspicious. We are suspicious, and that makes us more attentive and more watchful. You may depend upon it that if this cable is laid, the men who are moving now in it will have very little to do with the carrying out of the work. I have many contracts with our Government, and I can truly say that they are about the hardest bargainers I have ever come into contact with, and I have had a good deal of bargaining in my life. But when a bargain is made they stand by it, and we have no trouble. We know that they are strong, and that increases our strength. I am quite satisfied that there is no immediate prospect of contracts being inquired for in connection with this Pacific cable, but when they are you may depend upon it that I shall take good care that I know all about the matter. (Applause.)

Mr. BLUNDELL: On behalf of the shareholders, I should like to propose a vote of thanks to the officers and staff of the Company. I think this only due to them (hear, hear), although, perhaps, in our case results do not depend so much on individual efforts as they do in other cases; still, I think we should not be right in passing our executive over on this occasion. To them a measure of the success which has attended your efforts must be due, and I think when the proceedings of this meeting are circulated, our officers and staff both at home and abroad will be gratified at seeing that they have not been forgotten by the shareholders. (Applause.)

The CHAIRMAN: The relations between the administration and our staff generally are all that could be desired. We have never forgotten

Digitized by Google

our staff. We have never ceased to promote their welfare when we found it was desirable in the interest of the Company to do so. We have established for them a pension fund—a principle which Parliament has been talking about as regards old men for a very long time, and I believe that our action in this respect has given the greatest possible satisfaction. It affords me the greatest possible pleasure to be able to convey to the staff the expression of your approval and sympathy with them in their work. (Hear, hear.) I am always pleased when I find the services of the staff recognised, because, after all, we may have a very fine business, but unless there is the proper machinery to work it, it cannot go on satisfactorily. We have the proper machinery, I believe, in our staff. We value them, and I believe they value us.

The proceedings then terminated.

Metropolitan Electric Supply Company (Limited.)

The following is the report of the Directors, to be presented to the seventh ordinary general meeting, to be held at Winchester House, Old Broad street, E.C., on Monday next, the 23rd inst., at noon :—

The capital expenditure, which at the end of 1892 amounted to £550,859. 16s. 11d., now shows a total of £585,932. 8s. 9d., being an increase during the year of £35,072. 11s. 10d., principally owing to the continually growing extension of the Company's mains, to the cost of transformers and meters, and to providing connections to the premises of new consumers. The expenditure on buildings and machinery includes further payments on account of the Paddington plant, the sinking and fitting of a well for the more economical supply of water to the Sardinia-street station, and to works found necessary in connection with the foundations of the machinery at the Manchester-square station.

The gross revenue for the year amounted to £69,195. 4s. 4d., against £54,571. 19s. in 1892, being an increase of £14,623. 5s. 4d., as compared with the actual increase of £13,851. 19s. in 1892. A larger increase was fully expected ; but the exceptional brightness and absence of fogs during the winter months had a serious effect in diminishing the demand for light. In proof of this, it may be mentioned that while the revenue during each of the first three quarters of the year showed an increase of nearly 50 per cent. over the corresponding periods in 1892, the increase for the last quarter was only 8 per cent., although there was no falling off in the growth of the lamp connection.

The balance to the credit of the revenue account, before providing for depreciation, is £22,913. 15s. 2d. The Directors have set aside £7,000 as an addition to the Depreciation Fund, carrying to the credit of the net revenue account (No. V.) the sum of £15,913. 15s. 2d., which, with the balance brought forward from the last account, and other receipts, make a total of £18,512. 15s. 4d. After deducting bank charges and Debenture interest, there remains a balance of £14,548. 19s. 4d., of which the Directors, in pursuance of the policy commenced last year, have appropriated a further sum of £1,000 in reduction of the preliminary expenses account, which is now diminished to £3,052. 10s. 4d.

The Directors recommend that a dividend of 5s. per share on the Ordinary share capital be now paid, which will absorb a sum of £12,475, and leave a balance of £1,073. 19s. 4d. to be carried forward to the next account.

The number of 8-c.p. lamps supplied by the Company, increased during the year 1893 from 124,000 to 166,000. The present number of lamps connected is 175,000, and further applications continue to be received in satisfactory numbers.

A report from the Company's Chief Engineer shows that the satisfactory condition of the stations, machinery and plant has been maintained.

The Directors have to record, with the deepest regret, the death of two of their valued colleages, Sir James Anderson and Sir George Elliot, both of whom had been members of the Board from the commencement of the Company. It is not proposed at present to fill the vacancies thus caused. In accordance with the Articles of Association, the following Directors, viz., Admiral of the Fleet Lord John Hay, G.C.B., Joseph Charles Parkinson, Esq., and John Denison Pender, Esq., retire from the Board, and, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths and Co., also retire, and offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

CHADBURN AND SON (LIMITED).—This Company was registered on April 6th, with a capital of £30,000, in £1 shares, to enter into and carry into effect an agreement with William Chadburn for the acquisition of the business of a patentee and manufacturer of ships' telegraphs, optician, and nautical instrument maker carried on by him at Liverpool, and to carry on the said business in all its branches.

HOOPER'S TELEGRAPH AND INDIA-RUBBER WORKS (LIMITED).—This Company was registered on April 16th, with a capital of £50,000 in £10 shares, to enter into and carry out an agreement for the purchase of the business now carried on by the trustees of the late William Hooper at Millwall, and the property held in connection therewith ; to construct, manufacture, purchase, sell, deal in, lay down, let, work, maintain, repair, and keep in efficient working order submarine and land telegraphs and telephones, and telegraph, telephone, and electric lighting cables, wires, instruments, and appliances, and to carry on the business of electricians, telegraph and electrical engineers and contractors, submarine and other cable and instrument manufacturers, wire-drawers, wire ropemakers, suppliers of electricity for lighting, heating, and motive purposes, india-rubber and gutta percha manufacturers and merchants, asbestos manufacturers and merchants, &c. The subscribers are :—William E. L. Hooper (100 shares), Miss Alice L. R. Hooper (100), John P. Hooper (600), Mrs. Gabriel R. Moran (100), Miss Mary E. A. Hooper (100), Rev. Samuel F. Hooper (100), Mrs. Frank Marsh (100), C. A. Hooper (100), Mrs. A. M. Hooper (200), and Basil Gee (500). The first Directors are John P. Hooper and Basil Gee, who are the Managing Directors and managers.

SOUTH DEVONSHIRE GAS LIGHT AND COKE COMPANY (LIMITED).—This Company was registered on April 13th, with a capital of £10,000 in £1 shares, to enter into and carry into effect an agreement with Mr. Frank V. Thomas, and to carry on the business of a gas and electric lighting company in all its branches, and also the business of electricians, electrical and mechanical engineers, suppliers of gas and electricity, for the purposes of light, heat, motive power, and otherwise, electrical apparatus manufacturers, electrical contractors, &c.

JAMES TAYLOR (LIMITED).—This Company was registered on April 11th with a capital of £1,000 in £5 shares, to carry on the business of general ironmongers, electricians, &c., at Ramsbottom and elsewhere.

UNIVERSAL ELECTRIC LIGHTING COMPANY (LIMITED).—By an agreement made between John Tomlin, trading at 158, High-street, Camden Town, London, N.W., as "The Universal Electric Lighting Company," and the Company, the Company acquires the business carried on by the vendor, and in consideration agrees to allot to him or his nominees 6,000 shares, the nominal value of 10s. each, as fully paid.

HASTINGS AND ST. LEONARDS-ON-SEA ELECTRIC COMPANY (LIMITED).—The annual return of this Company, made up to April 3rd, has been filed. Out of a nominal capital of £50,000, in £10 shares, 2,261 have been taken up, and the full amount called upon each. As a result, £22,615 has been paid, which includes a sum of £5 paid on five forfeited shares.

WARD ELECTRICAL CAR COMPANY (LIMITED).—The annual return of this Company, made up to December 16th, was recently filed. The whole nominal capital of £300,000, in £10 shares has been taken up, and of these 29,993 were issued as fully paid to Michael R. Ward, of Trafalgar-buildings, Charing-cross, London, W.C. The full amount has been called and paid on the remaining shares.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—The annual return of this Company, made up to March 7th and recently filed, shows that the whole nominal capital of £300,000, in shares of £5 each, has been subscribed for and allotted, the full amount called, and £300,000 paid.

WOLVERHAMPTON ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—In reply to a request for the usual return of capital and shares of this Company, the secretary stated that the Directors desire that the name of the Company be struck off the Register.

WOOLWICH DISTRICT ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to March 14th, was recently filed, when 5,435 shares were taken up out of a nominal capital of £10,000, in £1 shares. Of these, 150 were issued as fully paid, and £5,285 has been paid in respect of the remainder.

WREXHAM AND DISTRICT ELECTRIC SUPPLY COMPANY (LIMITED). The annual return of this Company, made up to February 19th, has been recently filed. The nominal capital is £20,000, in £5 shares, and of these 115 have been subscribed for. No calls have yet been made.

CITY NOTES.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended April 15th were £840, as against £861 in the corresponding period of last year, being a decrease of £21. The total receipts for the half-year amount to £13,726, as against £13,717 for the corresponding period of last year, an increase of £9.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The following resolution has been passed by the Directors of this Company with regard to the £62,000 Six per Cent. Debenture debt, which falls due on May 1st next:—Resolved: "(*a*) To call up the balance of £1 unpaid on the Ordinary shares (£12,931). (*b*) To issue debentures for £30,000, having twenty years to run, and bearing interest at 4½ per cent. per annum. (*c*) To realise and take from the reserve fund the requisite balance, approximately £19,000, and pay off by those means the debentures falling due." The call for the unpaid £1 on the Ordinary shares is made payable on May 31st next.

HOBART ELECTRIC TRAMWAY COMPANY (LIMITED).—The traffic receipts for the month of March amounted to £1,416.

MIX AND GENEST (BERLIN).—The annual meeting of the shareholders of this Company took place on Monday last, when the report was submitted and adopted. The result of the year's trade showed a gross profit of 348,705 marks, and after writing off 78,192 marks for depreciation of plant, &c., and carrying to a reserve fund 10,000 marks, the Directors were able to declare a dividend of 8 per cent. on the paid-up capital. The constantly increasing business of this Company has necessitated the building of a new factory, and the orders, more particularly for telephone exchange work, have required the renting of two additional factories. With a view to centralise the manufacturing department the new building has been designed, the estimated cost of which would be 600,000 marks (£30,000), and the cost of acquiring the site (which is 6,653 square metres in extent) is 340,000 marks (£17,000).

ST. JAMES AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—The electric current sold by the Company for the quarter ended March 25, 1894, amounted to £10,375, as against £10,119 in the corresponding period of 1893.

Digitized by Google

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended April 13th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited) were £2,603.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the two weeks ending April 15th were £2,486, as compared with £2,801 for the corresponding period of last year. The December receipts, estimated at £5,255, realised £5,282.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 832.—Vol. XXXII. FRIDAY, APRIL 27, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

Much as we should like to see an extension of really good arc lighting in our most important thoroughfares, we are glad to learn that the Highways Committee of the London County Council have deferred further consideration of the lighting of the Victoria Embankment. The suggestions already made, and which happily have not been accepted, would simply ruin this masterpiece of the Metropolitan Board of Works. High posts down the middle of the road are questionable improvements to Tottenham Court-road and the Euston-road, which make no pretensions whatever to beauty, and would be hideous eyesores on the Embankment, though each one were a work of art in itself. The next idea was a row of posts alternating on each side. This arrangement, good enough for narrow streets, spoils even Queen Victoria-street at night. It has a niggardly appearance, being plainly enough the result of eking out, as far as possible, the few lamps allowed per mile. The finest feature of the Embankment is its splendid sweep, and at night this is emphasised rather than obliterated by the long single line of lamps on the parapet. An alternating hop-and-go-one zig-zag of widely-spaced high posts would be the very antithesis of the present system. The last suggestion was to widen the footway and plant posts on the new kerb, to clear the trees. As in its other proportions, the present width of the footway and of the carriage-way of the Embankment is admirable, and in this, as in other respects, it holds its own against the *quais* of Paris or any similar work.

The only objection that has been raised to the use of the posts on the parapet is that the trees would screen the light from the roadway. But does this objection really hold? The leaves have only begun to show during the past week, and light is not now wanted until after seven o'clock, when the bulk of the traffic, never very large, is over. Later in the evening, light is only wanted for purposes of public safety and morality, and for the return of a well-dined gourmet or two from a City feast. The leaves might interfere a little for an hour or so in October and November; but with a decent amount of lighting this would not be felt. From an intimate acquaintance with the Victoria Embankment, after walking its length several times a week for some years, we are convinced that the present standards on the parapet, perhaps the best of their kind in London, would be excellently adapted for arc lighting. The alternate posts might suffice, and the arc lamps should be specially selected, with compact or inverted mechanism, for the sake of appearance. While the County Council are naturally desirous of putting down a special plant for this work, it would be surely worth while to make an experiment, since it could be carried out at a very moderate expense. No less than five electric supply companies include parts of the Embankment in their districts, and some of these have mains almost up to the subway, and perhaps in it, for all we know. The wiring of the lamp posts is as easy a matter now as it was with the Jablochkoff lighting in 1884, and if there is any difficulty or objection to hiring lamps, why not have a competitive test of lamps and of carbons? If each maker sent only three lamps, three different kinds would suffice for more than a quarter of a mile of experimental lighting.

We are glad to see that the Postmaster-General has promised to give his careful consideration to the "plea for liberty" recently advanced on behalf of the boy-messenger service by a deputation of members of Parliament. That all State departments exist expressly for the public convenience and not for the express purpose of inconveniencing the public, is a truism which needs reiterating even in these days of triumphant collectivism, and especially is this the case in the matter of the Postal and Telegraph services. The deputation pleaded for a reduction of the sundry royalties now levied by the Post Office from the Company which stepped in where that stately department feared to tread. It would have been well to have also called the Postmaster-General's attention to the many vexatious hindrances still imposed by the Department over which he temporarily presides upon the full utilisation of the boy-messenger organisation by the public. Great, for instance, would be the convenience of being able to *telephone* a message to the office nearest the point of delivery, instead of being obliged, as at present, to ring up the office nearest to the starting point, and then send a boy half across London to the point of delivery. We confess to feeling that the petty, useful, almost domestic, functions which a free well-organised boy-messenger service would be called upon to perform, are perhaps scarcely compatible with the majesty of a State department, and, even putting aside all sentimental considerations of dignity, we doubt the possibility of making a State department sufficiently flexible. As we urged in the far more important matter of the telephones, so we say with regard to this purely local need, let the Post Office either perform the

Digitized by Google

service itself, or give a generous and a free hand to those who will do so, taking advantage of its undoubted legal rights to levy n the name of the State a purely nominal tax. An almost prohibitory tax levied by a department which does not care for the job, upon a concern which is enterprising enough to undertake it, is in the highest degree impolitic and inequitable.

THE recent meeting of the Metropolitan Electric Supply Company is one more instance of the fact that, whilst a concern is growing, and things are not going exactly to the liking of the ordinary shareholder, a chairman's speech is decidedly more interesting reading to the engineer and outsider than is the case when nothing but mutual congratulations upon a fat dividend have to be exchanged. "Ill blows the wind that profits nobody"; and we now learn that the fogs and dull days which usually adorn a London winter mean an extra 1½ per cent. dividend to the shareholders of the Metropolitan Company. Again, the inveterately economical habits of the British householder have, it seems, reduced the revenue per 8-candle lamp connected to the mains from the 25s. or 30s. anticipated by experts to a modest 8s. 9d. In the statement that the present plant of the Metropolitan Company, running day and night at full load, could generate the entire year's output in less than two months, we have yet another graphic illustration of the fortune awaiting the man who may be lucky enough to hit upon an electrical analogue of the gasometer, quick enough to take out a patent and shrewd enough to sell it on the crest of a big "boom." But to electrical engineers, perhaps the most interesting announcement made by the Chairman of the Metropolitan Company was that the time had arrived for "the institution of transformer sub-stations in some of the more crowded districts." The term transformer sub-station may mean anything from a pit in a pavement to a hollowed-out London square, and it is to be hoped that before the Metropolitan Company changes over irrevocably to one species or the other, figures will be available, setting forth their relative working values.

WE publish this week an abstract of a Paper describing the Glasgow electric supply station, which was recently read by Mr. W. ARNOT, the Corporation electrical engineer. A considerable portion of this Paper deals with the boiler and engine plant, and with the losses which occur in this section of the machinery. Some very instructive figures, the results of careful trials by Prof. KENNEDY and others, are given. There are station losses which Prof. KENNEDY has elsewhere characterised as "losses about which we engineers feel very sore, and which have no kind of respectable existence whatever;" and it is worth noticing that these constitute a large proportion of the station losses at Glasgow. No one will dispute the great reduction of risk of breakdown which results from the use of ring steam-mains, or any other duplicating system of steam distribution; and the arrangements in this respect at Glasgow are as perfect as may be. But, that it should ever be necessary to maintain the entire system of steam-mains under full pressure continuously, quite irrespective of the load on the station, or of whether the engines are or are not running, can only be regarded as deplorable. Scarcely any better encouragement for steam to liquefy could be devised than is offered by the by-ways and alleys of a system of steam-pipes shut down only at the engines. Condensation must take place on a wholesale scale, and there is little wonder that the stand-by boiler losses amount to practically 15 per cent. of the total fuel consumption at full load. This is a high price to pay for the security of a ring main; and, we may here remark, there is no need whatever for such a figure to be paid. The only plan which is consistent alike with security and economy is to shut down the remote sections of the main, and all the branches, whenever these are not actually required; and to shut down all the steam mains while the station is idle. The only alternative is to combine in the station the function of electric supply with that of a distilled water factory.

IT is very difficult to make a comparison, with any approach to accuracy, between the cost of a windmill plant and that of a gas or steam engine for electric lighting. In the estimate we made last week we said nothing about storage batteries, though we alluded to the highly complicated devices used in connection with them. Mr. ROLLASON, in his letter, which will be found elsewhere, takes a mean of 3 H.P. for 10 hours a day, giving 30 H.P. (he means, of course, horse-power hours), and "assuming the light is required for three hours a day, a gas engine, to accomplish this (direct lighting) would have to be of 10 H.P. working for three hours. . . ." But in this simple case no batteries would be wanted, while with the wind motor storage for two or three days would be needed. Mr. ROLLASON is fortunate in having meteorological records to refer to, and is doubtless able to make a very good estimate of the annual output to be expected from a windmill; but we think he will meet with much more success if he directs his attention to such work as pumping. In attempting to produce electric light he chooses the most difficult possible task to which a windmill can be applied, and one for which it is very unsuitable.

WE have received, this week, from Mr. MATHER a letter in reference to our remarks made in our last issue on the new form of shunt-box recently described. As regards the first point to which our correspondent refers, we see no reason for any modification of our statement. The assumption that the galvanometer had a serious amount of damping is justified simply by the fact that the working ratio of the shunt for quantity measurements sometimes differed from the corresponding ratio for current measurements by as much as 12 per cent. This difference can only be caused by the damping of the galvanometer swings, and is quite large enough to be called "serious." Moreover, in quoting our statement that the galvanometer was "badly suited for ballistic purposes," our correspondent has omitted to add the words, "if the ordinary form of shunt is to be used." This proviso greatly alters the meaning of the assertion. A ballistic galvanometer may behave well on open circuit, and yet its indications when used in a circuit metallically closed,

Digitized by Google

may not be comparable until certain corrections are applied. These correcting factors can, in such cases, be ascertained only after considerable trouble, and they vary with the resistance of the shunt, and the strength of the controlling field. The necessity for making these corrections justifies the assertion that such a galvanometer is badly suited for ballistic work when used with a shunt. In stating that such a galvanometer when used with the new form of shunt for the comparison of condenser discharges, gave no further trouble in this way, we were putting the case for the new shunt in the most favourable light. With a galvanometer whose damping does not vary much when the external circuit is altered, there is not so great an advantage over a shunt of the ordinary form.

The other statement alluded to by Mr. Mather, that the slight shunt error made in comparing currents could be explained by the want of proportionality in the galvanometer, we find, on re-examination of the numbers given in the Paper, to be erroneous, and the difference between the deflections must be attributed to an error caused by the shunt. The difference in question is, however, so small that the experiments do not show up the advantage of using the new form of shunt as much as would have been the case if the shunt selected had yielded a ratio differing more from its nominal value of 100 than 99·63.

Obituary.—The death is announced of Herr Paul Robert Kummer, of the well-known German electrical manufacturing firm of O. L. Kummer and Co., of Dresden.

Chicago Exhibition Buildings.—A Mr. Garrett, of St. Louis, has purchased the Chicago Exhibition buildings for £15,100, undertaking to have them cleared away by May 1, 1896.

Royal Institution.—Prof. Dewar will on Thursday, May 3rd, begin a course of lectures on "The Solid and Liquid States of Matter." On Saturday, May 5th, Capt. Abney delivers the first of the Tyndall lectures on "Colour Vision."

Cable Interruptions:	Date of Interruption.
Cayenne-Paramaribo	Oct. 25th, 1893.
Bissao-Bolama	Nov. 24th "
Brest-St. Pierre (P.Q. Co.)	Mar. 29th, 1894.

Old Students' Association.—We have been requested to announce that on Friday evening next the Old Students of the City and Guilds of London Institute will hold a smoking concert at Mason's Hall Tavern, Mason's-avenue, Basinghall-street.

The Society of Engineers.—We have received a copy of the recent Inaugural Address of the President of this Society, Mr. G. A. Goodwin. The Address consists in a somewhat lengthy and diffuse review of the present position of mechanical engineering progress, and discusses briefly each of the most important questions relating to the economical production and utilisation of mechanical power.

American Patent Office.—The business of the American Patent Office for the year 1893 shows total receipts of £248,574, against an expenditure giving a balance in the office's favour of £20,366. There were 38,473 applications for patents, against 25,102 in this country, and 23,670 patents were issued. Up to January 1, 1894, 521,700 patents have been granted by the United States, against 817,362 by all other countries.

The London Telephone Service.—The National Telephone Company announce that, in order that the telephonic service in London may be brought to a state of the highest efficiency, they have decided to introduce the twin-wire system, and for some time past have been making the necessary alterations and erecting new plant so as bring this system into use. The rearrangement of the Company's exchanges is said to render necessary alterations in the exchange numbers.

The Art of Definition.—The following is the definition of electrolysis which the *Mercury and Daily America*, of New York, supplies to its readers :—"Electrolysis is the name for the disintegration and destruction of gas and water pipes, caused by the electricity which escapes from trolley wires into the surrounding earth." After this we shall be told that electro-chemistry is the name for the exhibition in chemists' shop-windows of magnetic needles moved by "electrolysis."

An Electro-Chemical Journal.—We learn that a new monthly journal has been started in Berlin specially intended as the organ of the electro-chemical and electro-metallurgical industries. The new journal, which is entitled the *Electrochemische Zeitschrift*, is edited by Dr. Neuburger, and is published by Dr. N. von Klobukow through Fischer's Technologischer Verlag, Berlin. A long list of contributors has already been prepared, and includes the well-known names of Dr. Aron, Dr. Dürre, Prof. Goppelsroeder and Dr. Ostwald.

A Union of Incandescent Lamp Manufacturers.—An important meeting was held in Berlin last week at which representatives of all the leading makers of incandescent lamps in Europe assisted. The subject under discussion was the formation of a union of European incandescent lamp makers, and it was decided to take steps to form the same. At the same time the minimum prices of incandescent lamps were fixed at 75 pfennigs each to direct consumers, and 65 pfennigs to merchants and dealers.

The Hermite Process of Sanitation.—We have received a copy of a translation from the French of a report on some experiments relating to electrolysed sea-water prepared by the Hermite system. The experiments have been carried out by Dr. Piton, of the French navy; and the conclusion to which Dr. Piton arrives is, "that electrolysed sea-water is a perfect deodorant, and an excellent antiseptic, which rapidly destroys the most hardy micro-organism, always assuming a good contact between the micro-organism and the electrolysed solution."

India-Rubber.—The *Madagascar News* of March 17th announces that a rubber concession has just been granted to the Hon. John L. Waller, ex-United States Consul for Madagascar. The concession area measures 15 miles square, in the district of Fort Dauphin, on the south-east coast, and is conceded to be one of the richest rubber districts in the island. The discovery of rubber in this district is of recent date, and the article is of excellent quality. Mr. Waller states that he will stop the destruction of the rubber trees and vines by the natives so far as his concession is concerned, and preserve the product by having the milk extracted in a scientific manner.

Christiania Central Station.—This station, says our Scandinavian correspondent, has given an unusually good result for 1893. The estimated receipts were £7,335, and the estimated expenditure, including 5 per cent. interest on the whole of the cost, left an estimated surplus of £500. The actual result, however, is a surplus of £2,100. According to the estimate, it was thought that the average demand for private lighting would not exceed 6,000 lamps, but even by the beginning of February, 1893, 6,030 were connected up, and at the end of the year the number was 9,930. In addition to these, the central station supplied electricity to seven motors for hoisting, eight for ventilators, three for workshops, and three for various uses. Including the street lighting, the aggregate connection was 11,663 normal lamps. Of the 250 consumers, 100 were shops, 56 private offices, 9 municipal offices, 6 banks, 6 schools, &c. The average number of burning hours varied considerably for the different consumers; for public lighting the figure was 2,644 hours, railway stations 1,823, bodegas 1,391, printers 917, down to 129 hours for private residences, 184 for banks, &c. The average lighting hours have, on the whole, been very low.

Morecambe and its Water Gas. — According to the *Lancashire Evening Express*, the Morecambe people have got

Digitized by Google

the electric light, and yet they are not satisfied. They complain that in the making of it there is much that is offensive to their olfactory nerves, and a deputation has waited on the Local Board to complain. It seems the unused water-gas is let off for a few minutes at a time, frequently during the day and night, and the smell is very bad. Visitors complain, and say they will come no more. The property owners are so much in earnest about it that they say they will provide an inspector lodgings for a fortnight, so that he can judge for himself that what they say is true.

International Electrical Units.—*Electricity*, of New York, announces that the work of the International Congress in defining a set of standard electrical units has been embodied in a Bill to legalise the same introduced in Congress. The bill is entitled "An Act to Define and Establish the Legal Units of Electrical Measure." The second section of the Bill provides: "It shall be the duty of the National Academy of Sciences to prescribe and publish, as soon as possible after the passage of this act, such specifications of details as shall be necessary for the practical application of the definitions of the ampere and volt hereinbefore given, and such specifications shall be the standard specifications herein mentioned."

The People's Palace.—The Drapers' Company, supplementing their former benefactions, have just granted a special donation of £4,000 to the governors of the People's Palace so as to enable that body to construct and equip a separate engineering laboratory with workshops. The need has long been felt, but the lack of resources has hitherto prevented the governors from supplying it. Now, however, it will be possible to put into effect the scheme prepared by Prof. Holt, and erect a machine-shop—capable of accommodating 60 students—a pattern-making shop, a smithy, and an experimental workshop. We hope the benevolence of the patrons of this Institution will, on the next occasion, be directed to the electrical department, which, like the engineering department, is in need of assistance.

A Meter Box Arrangement.—We have received photographs of a Ferranti meter and fuses ensconced in a wooden box. The door is provided with a small glazed window. By way of preface to a description of this invention, it is hinted with a good deal of mystery that there are certain reasons and conveniences "neither necessary nor wise to explain," why meters should be thoroughly protected. "Every manager of an electricity supply company," we learn, "will doubtless understand the advisability of keeping an intelligent public from that little knowledge of electricity which is apt to be a very dangerous thing as far as the interests of the supply company are concerned." As long as the company have a locked-up main fuse, the intelligent consumer may surely do what he likes with his own fuse, and if any intelligent inhabitant of Hull, where this "combination" has been invented, knows how to dodge a Ferranti meter, he is to be credited with a good deal more than "a little knowledge of electricity."

The Grafton High speed Steam Engine.—At the meeting of the Institution of Mechanical Engineers, on Thursday last, a Paper was read by Mr. E. W. Anderson, describing the Grafton high-speed steam-engine. As at present built, this engine is single-acting and non-compound, being of the vertical type, with steam admission on the down stroke. The arrangements for the distribution of steam are decidedly novel, and are designed to give high speed with low engine friction. The cylinder liner is in two parts, an upper and a lower part, and through the annular orifice between these two liners, steam is admitted from the steam-chest. There are two pistons, one above the other, working in the cylinder, which is open at both ends, and the cranks of these two pistons are usually set at 135°. The upper piston controls the distribution of steam, and thus serves the double purpose of a piston valve and a working piston. The cranks are loaded to balance the inequality of piston loads, and thus to obviate vibration. One feature of the engine is the large amount of compression which takes place after exhaust. Diagrams of a 12in. engine, with an effective stroke of 6¼in. were shown. This particular size is designed to run at from 600 to 650 revolutions per minute, indicating 40 H.P. with 100lb. steam, but smaller sizes are constructed to run up to 900 revolutions per minute.

Hanover.—The report of the Hanover Electric Supply Station for the year 1892-93 has resently been published. The total costs, including taxes, cost of working and superintendence, repairs and sundries (omitting only interest and depreciation), amount to 20·76pf. per kilowatt hour, approximately, 2·60d. To this are added 17·88pf. = 2·24d. for interest, and 26·13pf. = 3·26d. for depreciation, &c., a total of 8·1d. per kilowatt hour. The receipts for current are 69·07pf., and sundries 6·66pf., a total of 75·73pf., or 9·46d. per kilowatt hour. The following table summarises other details. It must be remembered that this is a direct-current station with accumulators, dynamos by Schuckert, of 400 and 600 H.P. :—

Year.	No. of kilowatts on mains.	Energy supplied kilowatt hours.	Av. Price	Ex-penses.	Re-ceipts.	Written off.	Profit.
			d.	£	£	£	£
1891-92..	643·4	355,364	8·8	7,708	14,743	4,534	2,500
1892-93..	738·9	365,114	8·6	8,078	14,847	4,769	2,000

In connection with these costs, we note that the coal, which burned quite smokelessly and left 9·8 per cent. of ash, cost, delivered at the works, about £7. 10s. per 10,000 kilogrammes (22,000lb.), or, say, 15s. a ton.

Electricity Meters.—A descriptive Paper on this subject was read at the last meeting of the Northern Society of Electrical Engineers, by Mr. R. P. Wilson and an interesting discussion followed. Mr. Wordingham remarked that there was one point worth mentioning in testing watt-hour meters, "one must either cheat the consumer or the Company Of course, what the consumer should pay for is the current through his lamps multiplied by the pressure at the lamps. Now, if the shunt winding be connected on the main side of the meter, the company is supplying a higher pressure than they get paid for. If on the other hand the shunt winding is connected to the consumer's side of the meter, the consumer pays for the current used in the shunt coil of the meter, which is, of course, no benefit to him." Mr. F. P. Bennett stated that some time ago he had made a test of the different shunt meters, viz., the Frager, Thomson, Reckenzaun, &c., and he found that the average current absorbed was about 10 milliamperes. If there were 1,000 such meters installed in a town, the current absorbed by the shunt would be equal to one Board of Trade unit per hour, and as there were 8,736 hours in the year, that number of Board of Trade units would be wasted, the total exceeding 11,000 E H.P. hours. He considered that a very substantial objection to shunt meters. In his reply, Mr. Wilson pointed out that the shunt current of a meter was used for the specific purpose of overcoming initial friction. In doing so, all its energy was absorbed, and, therefore, could not communicate itself to the dials. There was no doubt, he said, that the manufacturers who used shunts in their meters were quite alive to the objections raised against them, but they were of opinion that the shunt had advantages which more than compensated for the annual consumption they involved.

An Electrical Method of Heating Oxygen for Spectrum Investigations.—In a recent communication to the Académie des Sciences, M. J. Janssen described an apparatus devised by him for the purpose of investigating the spectrum of oxygen when the gas is submitted to a high temperature and pressure, with a view of determining the nature of the spectrum, which one might expect to find in the case of any oxygen existing in the lower solar atmosphere. M. Janssen's great difficulty was to heat the oxygen in the ordinary way to the required temperature whilst the gas was under great pressure. To overcome the difficulty, however, he resorted to electricity, and the following is the arrangement used by him. A steel rod 2·2 metres long and 6 centimetres in diameter was bored out to a diameter of 3 centimetres. The tube so formed is capable of resisting a pressure of more than 1,000 atmospheres. Its extremities are closed by screw sleeves containing glass or quartz plugs. The column of gas contained in this tube is heated by means of platinum spiral, traversing its entire length,

Digitized by Google

and insulated by means of asbestos lagging which assists, moreover, in preventing the transmission of the heat through the walls of the tube. At the ends of the tube the spiral passes out through copper plugs which are insulated from the tube by means of a ring of ivory or compressed fibre. By means of this arrangement the spiral can be brought to any temperature between red and white heat, and communicates these temperatures to the column of gas without sensibly heating the walls of the tube. M. Janssen remarks that the whirls and motions taken up by the column of gas when submitted to the action of the white-hot spiral, often diminishes to an enormous extent the amount of light transmitted through the tube. He points out, however, that if the tube is arranged in a vertical position, the layers of the gas tend to arrange themselves horizontally, and to become, therefore, normal to the rays of light, and in this way the amount of light absorbed is diminished by an unexpected amount.

American Bell Telephone Company.—The report of the American Bell Telephone Company for the year 1893 shows an increase of 13 per cent. in the gross earnings, which now stand at £1,156,000, and of 15 per cent. in the net earnings, which aggregate £785,000. The following statistics are of interest:—Instruments under rental December 20, 1893, 566,491, an increase of £13,771 in twelve months. Exchanges January 1, 1894, 838, an increase of 26 in a year; underground wire mileage, 120,675; increase, 30,459. Total miles of wire, 353,480; increase, 45,689. Employés, 10,421. The largest amount of underground wire in use in a single city is 30,397 miles in New York, 18,554 in Chicago, 8,361 in Boston, 6,972 in Brooklyn, 5,719 in Pittsburgh, 5,242 in Milwaukee, 4,409 in Detroit, 4,345 in Cincinnati, 4,314 in Baltimore, and 4,047 in San Francisco. At the close of 1893 more than one-third of the exchange wire mileage was underground. The metallic service subscribers increased 23,053 to 37,648. The report says further: "The general system of the operating companies throughout the country has been to charge the subscriber a fixed sum for exchange service, graduated according to the class of equipment which he selects, and leaving him free to use the service as much or as little as he chooses. On the whole, this plan appears to have worked to the satisfaction of subscribers, and in a measure distributes equitably the charge which the public pays for telephone service, since in the smaller exchanges, where the average use is the least, the charges are correspondingly small, while in the great cities, where of necessity the rates are highest, the average use is also greatest. It is by no means certain, however, that, in time to come, the companies and their patrons may not find a system of tariff rates, that is, the charging the subscriber according to the number of times his telephone is used, more equitable than the present system of uniform charges. Some experiments are in hand to see if in the great cities the case of those who want only a limited use of the telephone at a less rate than is fixed for an unlimited use can be met."

Lubricants.—At the last meeting of the Junior Engineering Society, held at the Westminster Palace Hotel on the 13th inst., a Paper on "Lubricants: Their Use, Testing and Analysis," was read by Mr. W. F. E. Seymour, of Swindon. The necessity of efficient lubrication and importance of being able to judge the utility of various lubricants for different kinds of work was first pointed out. Lubricants might be classed into solids, semi-solids, and liquids. The composition of vegetable, land animals, fish and mineral oils was considered and their proper applications referred to. The author next gave an extended account of the more important lubricants, tallow, rape, olive and castor oils, and detailed the uses to which they were each best adapted. Of mechanical testing appliances, Ingram and Stapfar's oil-tester, and Thurston's machine were illustrated, and the mode of working and of recording the results were shown. The suitability of a lubricant for any particular duty could be judged by its viscosity and specific gravity, in the determination of which various forms of instruments were employed. The principal viscometers used were Boverton Redwood's and Sackar's; these were described and the process of working with them explained. Passing on to chemical analysis, the methods adopted for the determinations of free acid, drying properties, flashing point, mineral matter, congealing point, total fatty acids, mineral oil or unsaponifiable matter were given. An appendix to the Paper was devoted to Maumené's test, Pontet's classification of Valenta's acetic acid test, Dalican's method for congealing-point of tallow, and Gray's flash-point apparatus. In illustration of the Paper, specimens of the various oils were shown for examination, and there were also a number of instruments exhibited which had been sent by Messrs. Baird and Tatlock. Mr. L. W. Gates opened the discussion, the other speakers being Mr. W. B. Clarke, Mr. H. M. Rounthwaite, Mr. G. E. Brown, Mr. R. W. Newman, and the chairman, Mr. Percy J. Waldram.

Electric Power in Engineering and Iron Works.—At the meeting of the Cleveland Institution of Engineers, on the 9th inst., at Middlesbrough, Mr. J. Phillips Bedson, of the new Cleveland Wire and Ironworks, Middlesbrough, read a Paper by Mr. D. Selby-Bigge, of Newcastle-on-Tyne, on this subject. The following is an abstract:—The writer desired in his Paper to draw the attention of engineers to short-distance transmission, or concentration of power. In order fully to grasp this idea, he would take the case of any large engineering works in which the motive power was derived from a number of scattered and auxiliary steam-engines, which in some cases were used for driving shafting in fitting-shops, and in other cases were applied to various machine tools, hot saws, cold saws, rolls, forge blowers, punching, and shearing machines, straightening machines, planing machines, and the numberless other apparatus which were daily employed in engineering establishments. Cases were often found in which numbers of pumping and shearing machines were driven by means of belts and pulleys, receiving their power through long lines of main shafting and countershafting. In many cases the boilers necessary for producing steam for all these engines were situated at a considerable distance from them, and the steam had to be conveyed through long lengths of pipe. The boilers, instead of being all concentrated together in one battery, were scattered about the works. Such were the conditions daily met with when looking through engineering establishments. The writer then set himself to show how short-distance electric power plant could be advantageously adopted, and what great economies could be realised by a concentration of all that scattered power. (1) Taking the case of separate engines for driving individual machinery, it would readily be admitted by all engineers that much better steam economy could be obtained from the employment of one large highly-efficient engine than from a large number of small engines, which for many reasons were not of so efficient a character, the steam consumption in each of the small engines being proportionately four to six times greater than it would be in a large engine of a triple-expansion condensing type. (2) Taking the case of a machine-shop driving-off shafting, there was considerable loss incurred in transmitting power through long lines of mains and countershafting with all the attendant gear wheels, bearings, pulleys, belts, &c, this loss varying from 20 per cent. up to 60 per cent. of the power transmitted. (3) The disadvantage of having boilers at long distances from the engines they had to drive did not need to be recounted, nor the inconvenience of having boilers scattered about, and the efficiency of working at a low pressure. All these disadvantages could be obviated by a well-considered application of electric power With an ideal electric-power plant there would be self-contained electric machine tools, in which the motor would be embodied as part of the machine; but in existing works this was difficult to realise, and the method was either to drive by belt on to existing fly-wheels, or else couple the motors direct by means of gearing. The very small loss in distributing the power through cables was a matter which must be evident to all engineers, when compared side by side with long lengths of shafting or of steam pipe, in which condensation and loss of power were bound to take place. The writer mentioned that three large works in Middlesbrough had already adopted or were adopting the use of electricity as a motive power, and several other manufacturers had the matter under consideration. In Belgium and Germany large works were operated exclusively by electricity, and had been running for three years with very remarkable results as regarded economy.

Steam.

Steam Equations.—The properties of saturated steam represented by the set of curves in Fig. 9 may be approximately represented by a series of empirical equations. In the following equations the symbols refer to the same quantities respectively as the symbols on the curves:—

$$H = 1081{\cdot}4 + 0.305\,t \quad . \; . \; . \; . \; . \; . \; . \quad (69)$$

$$t = \frac{2938{\cdot}1}{6{\cdot}19935 - \log p} - 371{\cdot}85 \quad . \; . \; . \quad (70)$$

where log p is the common logarithm of the absolute pressure in pounds per square inch.

$$L = 1115{\cdot}2 - 0{\cdot}708\,t \quad . \; . \; . \; . \; . \; . \; . \quad (71)$$

$$V = \frac{330{\cdot}36}{p^{0{\cdot}941}} \quad . \; . \; . \; . \; . \; . \; . \; . \; . \quad (72).$$

This last equation may conveniently be expressed as follows—

$$\log V = 2{\cdot}519 - 0{\cdot}941 \log p \quad . \; . \; . \; . \; . \quad (73).$$

Curves (e) and (f) are, of course, most simply represented by equation (67).

Isentropic Expansion of Saturated Steam.—In order to study the behaviour of any mass of saturated steam when expanded isentropically, it will be simplest first to consider what happens when we arrange to expand the steam in such a way that the whole of it is just saturated throughout the expansion. The expansion in this case will take place along the curve (d) in Fig. 9; and the work done per pound of steam, in expanding between any two limits of volume, will be represented by the area subtended by the portion of the curve between these two limits upon the axis of volume. Integrating this area in any case, we may compare the work done by the steam with the amounts of its energy before and after the operation. We shall always find that the work done per pound of steam will be greater than the difference between its original and its final heat. Now this can only arise from the fact that heat has been supplied to the steam during its expansion; for if no energy is supplied it is impossible that more work can be done than is equal to the difference between the initial and final energy. Therefore, to obtain expansion of steam along the saturation line, heat must be continually added to the steam while it is expanding.

As a direct result of the foregoing facts, we may infer that if saturated steam is expanded and does work, without having any heat supplied to the steam during the operation, it is impossible that the whole of the steam can continue in the state of saturated vapour. The work will be done at such a rate that there will not remain enough energy in the steam to keep the whole of it saturated; and a portion of the steam will condense to water. The remainder of the steam will, of course, be in a condition of saturation; but its pressure and its temperature will both be lower than in the corresponding volume with saturation expansion. The work done by the steam will also be less than in the former case; but the efficiency is not necessarily less, as less heat need be supplied to the steam. The adiabatic expansion of saturated steam follows approximately the following law:—

$$P\,V^{\frac{10}{9}} = \text{a constant} \quad . \; . \; . \; . \quad (74)$$

or, $$\log P + 1{\cdot}111 \log V = \text{a constant} \quad . \; . \quad (75)$$

Liquefaction.—The production of water, by the liquefaction of steam during adiabatic expansion, is an important phenomenon; especially when we remember that in high-speed engines this condition of expansion is approximately attained. When we remember that steam is only water with energy added to it, and that it is the business of the steam engine to take as much of that energy as possible out of the steam, we shall be prepared to look on this form of liquefaction as a necessity, and not as a thing to be avoided. Practically, as we shall see later, the liquefaction of steam on this account is complicated by other considerations. But the fact remains that, in proportion as we utilise the intrinsic energy of the steam in an engine, so we must expect to find a certain amount of liquefaction taking place; that is to say, the further the isentropic expansion is carried the larger will be the percentage of steam liquefied.

Prevention of Liquefaction.—For practical reasons it is sometimes, though not always, advisable to take special precautions to prevent the liquefaction of steam during expansion. Theoretically, all such devices are inferior to the practice of allowing liquefaction to go on; and they must yield a lower value of theoretical efficiency. There are two such practical expedients in general use: the steam jacket and the superheater.

Steam Jacket.—The former of these consists of an envelope of hot or "live" steam surrounding the cylinder in which expansion takes place; in some instances the jacket being supplied with hotter steam than that used in the cylinder. Between the jacket space and the cylinder space there is a highly conducting liner of iron or steel; and, except under unfavourable circumstances, heat will pass from the jacket steam to the expanding cylinder steam, and will more or less perfectly prevent liquefaction in the cylinder, though an equivalent amount of liquefaction will, of course, take place in the jacket. Owing to the piston speed, the heat will not pass from the jacket fast enough to maintain a constant temperature in the cylinder; and the rate of fall in temperature of the cylinder steam increases as this speed is increased. Thus, it may happen that the jacket may keep the whole of the steam exactly saturated. Or, on the one hand, it may happen that more than the amount of heat requisite for this may pass, and the steam may be slightly superheated, or water may be evaporated into the steam; or, on the other hand, during the more rapid motion of the piston heat may pass too slowly, causing liquefaction, while later, when the piston is moving more slowly, the flow of heat may be sufficient to re-evaporate some or all of the water thus produced. The steam jacket has another duty, which will be considered later; but all its duties may be summed up by saying that it is designed to so supply heat to the cylinder steam that that steam shall not leave the state of vapour until it has been exhausted from the engine.

Superheating.—It is possible, however, to supply the steam beforehand with the extra stock of heat which is necessary to prevent it liquefying in the cylinder. This may be done by giving the steam a certain number of degrees of superheat, arranging that the amount of heat added to each pound of steam shall be sufficient for its expansion without liquefaction. The proper limit of superheating has been attained when the exhaust steam is neither superheated nor wet, but is just saturated. Any excess of superheat above this is heat directly thrown away; and any deficiency in the amount will lead to liquefaction. The steam is superheated on its passage from the steam generator to the engine. Considered as devices for letting the working substance carry away as much energy as possible into the exhaust, both the steam jacket and the superheater are admirably adapted to the purpose; and there is no doubt that, from this point of view, they both increase the thermodynamic inefficiency of the steam engine. Considered as necessary evils, they may stimulate engineers to endeavour to so modify the conditions of steam practice as that they shall no longer be necessary.

Wiredrawing.—Steam is said to be wiredrawn when it flows from any pressure to a lower pressure against the frictional resistance of a constricting conduit, such as a steam pipe or orifice. The term *throttling* is sometimes applied to the operation of wiredrawing steam through a constricting valve in such a way as to considerably lower the pressure of the steam. Owing to the imperfect elasticity of steam, its expansion under wiredrawing is accompanied by loss of energy by internal work; but if the ratio of expansion is small this loss is practically inconsiderable, and in any case it must occur either in the conduits or in the engine. If dry saturated steam is wiredrawn, the heat developed in overcoming the friction is partially absorbed by the steam and partially, but to a much less

Digitized by Google

extent in good systems, absorbed by the metal of the pipe. The result is the formation of a low-pressure superheated steam but little lower in temperature than the high-pressure saturated steam from which it was wiredrawn. Apart from the loss just mentioned, the only source of inefficiency in this wiredrawn steam is the loss of availability of heat due to the lowering of its temperature. If wet steam is wiredrawn, the heat developed in overcoming friction will also partially be absorbed by the steam. But the presence of water will prevent superheating, and will cause the temperature of the steam at the lowered pressure to correspond to that of saturation at this pressure; while the heat absorbed by the steam will evaporate some of the water. Wiredrawing wet steam, therefore, has the effect of more or less completely drying it; but the large fall in temperature which will occur with excessive wiredrawing must result in a large loss of heat-availability, especially at low pressures. It will in most cases be more efficient to separate the water from the high-pressure steam before wiredrawing it, than to allow the wiredrawing to take place with very wet steam; and this is the more particularly the case where wiredrawing or throttling is adopted for the purpose of running an engine on a light load. Thermodynamically, wiredrawing wet steam is equivalent to bringing dry steam into contact with a small mass of cold water in an expanded chamber.

Furnaces and Boilers.

Principal Details of Steam Generators.—The purpose of the steam generator is the efficient production of the working substance, namely dry saturated or superheated steam in a state as nearly as possible that in which the engine requires it, allowance being made for unavoidable changes in the quality of the steam during its transit from the generator to the engine. Steam generators may be considered to consist of two principal details; the furnace and the boiler. The parts of the furnace comprise: the grate, combustion chamber, fire-door, ash-pit and door, bridge, internal and external flues, economiser, superheater, chimney, and the draught regulating and producing apparatus. The duty of the furnace is to produce economical combustion of the fuel, to distribute the heat of the hot gases to the useful heating surface and to reject the waste gases in a proper and efficient manner. The parts of the boiler comprise: the useful heating surface, the water space, the steam space, the enclosing shell, feed apparatus, steam pipes, various discharge pipes, safety apparatus, indicating apparatus, valves and steam drying apparatus. The prime duty of the boiler is to abstract as much heat as possible from the furnace gases, consistently with the proper working of the furnace, and to utilise as much as possible of this heat in producing steam at the requisite pressure and of the requisite quality. The whole generator is sometimes fixed in brick setting, and is always surrounded with a lagging of non-conducting material. The arrangement of these details differs very much in different types, and many of them are modified according to the nature of the fuel to be burned. Except where otherwise stated, it will be assumed throughout this series that the plant is arranged for steam-coal consumption.

Types of Boilers.—In ordinary language the term boiler is applied to the whole steam generator. Without going back into ancient history, we may consider the following types of boilers, all of which are in use for electrical purposes at the present time:—(1) The Cornish boiler; consisting of a cylindrical shell of riveted wrought iron or steel plate, with flat ends, one internal cylindrical flue containing at the front end the grate, and various arrangements of setting forming the external flues. For electric power purposes, these boilers are made up to 28ft. in length and 7ft. diameter of external shell. (2) The Lancashire boiler; which differs from the Cornish boiler only in having two internal cylindrical flues, each with a separate grate, and in certain small alterations in general proportions. There is a greater proportion of useful heating surface in the Lancashire than in the Cornish boiler, for the same size of shell. These boilers are made for electrical purposes up to 28ft. in length and 8ft. 6in, in diameter; though even larger sizes are occasionally used where land is cheap. (3) The locomotive boiler, which is self-contained, in that all the heating surface is comprised within the boiler and independently of external setting. This type of boiler is not solely used for locomotive purposes, and is commonly met with in small electric-power stations. From the fact of its having originated as a boiler for locomotives, it has derived the name which has clung to it. In this type of boiler there is a cylindrical shell fitted at the fireplace end with a double fire-box and at the other end with a smoke-box and chimney; while the inner fire-box is connected to the smoke-box by a large number of small horizontal fire-tubes. The inner fire-box contains the grate at its lower end; and the space between the two fire-boxes is used as water space. The amount of heating surface in this type of boiler is very large indeed, in comparison with other types. (4) The return tube boiler, which closely resembles the marine type in its best examples. This consists of a horizontal cylindrical shell, fitted in the lower part with one or more cylindrical flues, each with a separate grate, and in the part immediately over those flues fitted with a large number of fire-tubes, as in the locomotive boiler. The hot gases pass to the back along the lower flues, and return to the front through the numerous fire-tubes; they then, as a rule, pass through a system of external flues, as in the Cornish and Lancashire types. (5) Water-tube boilers, which consist of a combination of a furnace and external flues with a large number of tubes filled with water, these tubes being in communication with a cylindrical shell partly filled with water and partly with steam. One of the most important electric power boilers, namely, that manufactured by Messrs. Babcock & Wilcox, belongs to this class. Besides these well-defined types, there are important electric power boilers which are combinations of two or more types, such as the Galloway boiler; and in addition to these, there is a heterogeneous collection of boilers for small motive power, which it is not in the province of this work to notice.

(To be continued.)

MAGNETIC QUALITIES OF IRON.*

BY J. A. EWING, F.R.S., AND MISS HELEN G. KLAASSEN.

(Continued from page 672.)

Experiments on the Heating Effect of Reversals of Magnetism.

In another section of our experiments direct measurements were made of the amount of heat generated by reversals of magnetism.

Some of the rings employed in the tests which have just been described were again used in these experiments, and under precisely the same conditions.

The method employed (a short account of which was pub lished in *The Electrician* of October 9, 1891), depended on the use of two exactly similar rings, one of which had its iron core subjected to magnetic reversals, while heat was developed in the other by the passage of a steady electric current. This steady current was adjusted until the rate at which heat was generated by the current in one ring became the same as the rate at which heat was generated by reversals of magnetism in the other ring, equality of temperature as between the two rings being tested by means of a thermo-electric circuit with a pair of junctions, one embedded within the core of each ring. The current which was used to magnetise the one ring passed also round the other, in a coil which had the same dimensions as the magnetising coil of the first ring, but which was wound non-inductively. Hence, whatever heating effect the magnetising current had on one ring, it also had on the other, though one ring only became magnetised. Both rings were subjected to precisely the same thermal influence, except that in the active ring the magnetism of the core was periodically reversed, and in the inactive ring a special heating current was used to balance the heat generated in the other by these magnetic reversals. The arrangements were in all cases such that the inactive ring could be made magnetically active and *vice*

* Abstract of Paper read before the Royal Society.

versâ, without any change in the winding or structure of the rings, by merely changing the electrical connections of the divided coils which were wound in identical fashion on each. In those of the experiments that dealt with rings which had a core of insulated iron wire, the heating current was caused to pass through the wire of the core itself in the inactive ring—a particularly satisfactory arrangement, inasmuch as the heat generated by this current in the inactive ring was then distributed throughout the core in just the same way as the heat generated by magnetic reversals in the active ring. In experiments dealing with sheet metal cores a special coil was wound as close as possible to the core of the inactive ring to take the heating current.

This method of measuring the heat due to magnetic hysteresis by securing a thermal balance between two rings, alike in all respects, was originally devised to give an answer to the question whether, when a transformer is in action, the heating of the core through magnetic hysteresis is the same when the transformer is "loaded," or when it is not; in other words, whether the taking of current from the secondary coil has any influence on the amount of heat generated in the core, the limits of magnetisation and the frequency of the reversals being unaltered. Independent experiments by Prof. Ryan, Mr. Morley, and Prof. Ayrton, on the efficiency of transformers, had apparently agreed on showing a marked reduction in the loss of energy due to magnetic reversals when the "load" was put on. Adding a secondary coil to each of our rings to make it into a transformer, we applied the above balance method to compare the rate of magnetic heating when the secondary was open with the rate when the secondary was closed through a low resistance, so as to apply a heavy "load," arrangements being at the same time used to keep the magnetic range and frequency unchanged. The result was that no change could be detected in the rate at which heat was produced by the reversal of magnetism when the "load" on the secondary coil was varied from nothing to an amount greatly in excess of any "load" used in practical transformers.* The conclusion being of this negative kind, a very short account of the experiments will suffice.

The electrical connections are shown in Fig. 24. On each ring of the pair a primary coil was wound in two layers, and a secondary coil, also in two layers. In each coil the two layers had the same number of turns, and the number was the same on both rings. The two layers, both of primary and of secondary, could be connected either inductively or non-inductively. They were each wound uniformly round the whole of the ring. On one ring they were connected inductively, and were respectively in series with the non-inductive primary and secondary of the other ring. Hence all direct thermal action of primary and secondary currents was the same for both rings. The magnetic reversals were caused by passing through the primary circuit the current from an alternating dynamo, which could be run at various speeds, and the strength of this current was adjusted, by means of a liquid rheostat, R_1, in its circuit, to secure that the magnetisation should have the same limiting value when the secondary circuit was closed (through the resistance R_3) as when it was open. To test the constancy in the limit of magnetisation a voltmeter, V_1, of special construction was used, which was connected to a special induction coil of a few turns wound on each ring. The voltmeter was of the hot-wire type; it consisted of a piece of very fine platinum wire, stretched between supports, but deflected sideways, after the manner of the wire in Profs. Perry and Ayton's voltmeter, by a light spring pulling transversely in the middle of the wire's length. The middle portion of the wire stood in the field of a microscope, and its transverse movements were read on a micrometer scale in the eye-piece. This was found to form a very convenient means of reading alternating electromotive forces of one or two volts and under. Owing to the small section of the wire and the freedom from friction which was secured by having no mechanical indicating gear, the instrument responded quickly and exactly to change of electromotive force, and allowed the necessary adjustment of the primary alternating current to be made with great nicety. In most of the experiments a Cardew voltmeter, V_2, was also connected across the terminals of the primary circuit. Its response to small changes was much less rapid and certain, but its absolute graduations furnished a convenient means of estimating the intensity of magnetisation from the amount of back electromotive force.

The heating due to magnetic reversals in the active ring was determined by seeing what strength of steady current in the core of the inactive ring would maintain a balance in the thermo-electric circuit. The heating current was adjusted by means of R_2, so that, after both rings had been brought to the same temperature, the two temperatures remained equal while both rose. The thermo-electric junctions were connected to oppose each other through a sensitive galvanometer, but an alternative connection could be made in which one junction only acted on the galvanometer, so that the temperature of the ring might be estimated at any stage in the experiment. It was necessary, in fact, to record the temperature of the ring from time to time to allow for change in the resistance of the iron wire forming its core.

The following will serve as an example of the readings taken. It refers to an experiment upon a pair of precisely similar rings, one of which was the Ring VII. of the tests already described.

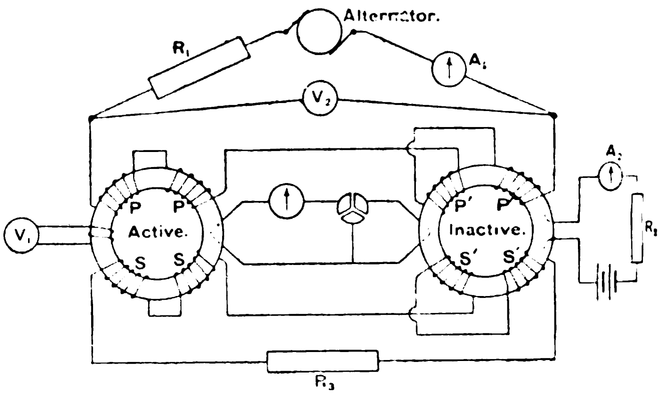

FIG. 24.

The core consisted of iron wire, insulated with cotton. The frequency in this experiment was 133 periods per second, and the greatest value of **B** was about 7,500.

(*a*) With secondary open:—

Heating current, in amperes.	Reading of Cardew voltmeter.	Resistance of iron core.
0·75 (too strong)	22	5·85
0·65 (too weak)	22	to
0·7 (balance)	22	5·90

(*b*) With secondary closed through a low resistance:—

Heating current, in amperes.	Reading of Cardew voltmeter.	Resistance of iron core.
0·75 (too strong)	24½	5·80
0·65 (too weak)	to	to
0·7 (balance)	24	5·90

The reading of the microscope hot-wire voltmeter was the same in both parts of the experiment, the difference in the Cardew readings being due to the greater volume of magnetising current that was required when the secondary circuit was closed. It will be seen that no difference could be detected in the amount of balancing current necessary to maintain equality of temperature. Other experiments gave confirmatory and quite conclusive results. One more may be quoted:—

Frequency 69 periods per second. Greatest value of **B** about 13,500.

(*a*) Secondary open. Balancing current 236 on arbitrary scale.

(*b*) Secondary *short circuited*. Balance with current between 231 and 244.

* Since these experiments were made (and briefly published in *The Electrician* of December 4, 1891), later tests of transformers, by Prof. Fleming and others, have borne out our conclusion that the amount of "load" has no influence on the waste of energy through magnetic hysteresis.

Digitized by Google

The heating effect of reversals is, of course, due to Foucault currents, as well as to magnetic hysteresis. An attempt was made to compare the total heating effect, measured directly by reference to the balancing current in the inactive core with the value of $\int H\, dI$, as found in the preceding experiments, with the view of estimating the influence of Foucault currents. But the value of such a comparison depends on our being able to estimate the maximum of magnetisation in the cycle, and this is by no means a simple matter. The observed E.M.F. gives the mean value of $(d\,B/d\,t)^2$, and to calculate B from this it is often assumed that the mode of variation of B may be treated as simply harmonic, in which case we should have—

$$\text{Maximum } B = \frac{10^8 . E}{\pi n N A \sqrt{2}},$$

where E is the observed electromotive force in a coil of N turns, the area of curve-section of the iron being A and the frequency n. But even if the magnetising force were simply harmonic it is otherwise with B, whose increment and decrement is largely affected by magnetic hysteresis. The relation of maximum B to mean $(d\,B/d\,t)^2$ could be determined if the form of the curve of B and t were known. Recent experiments—amongst others, those of Dr. John Hopkinson and Messrs. Wilson and Lydall,* in which B as well as $d\,B/d\,t$ has been determined as a function of t in a ring submitted to alternating magnetic forces—exemplify how wide the variation from a sine-function is likely to be. In view of this consideration, and of the fact that no such data were at hand in the case of our own tests, we have not followed up this method of directly measuring the heat produced by reversals.

Experiments made with the Magnetic Curve Tracer.

When the magnetism of a piece of iron is reversed rapidly more work is spent than when the reversal takes place slowly. Whether all the extra work done in the former case is to be set down to Foucault currents is, perhaps, an open question; there may be a genuine time-lag in the process of magnetisation, independent of the effect of Foucault currents, though not readily distinguishable experimentally from their effect. This quasi-viscosity, distinct from Foucault-current effects, will, if it exists, require higher values of H to be applied than would otherwise be necessary when any assigned limits of B are to be quickly reached. At high speeds of reversal the curve which shows the relation of the externally-applied magnetising force to B becomes swelled out and encloses a larger area, corresponding to the greater amount of work then done, whether in generating Foucault currents or in overcoming this other possible source of quasi-viscous resistance. That an increased amount of energy is expended is clear from experiments of the kind which have just been referred to, even if the exact interpretation of these results is somewhat doubtful through uncertainty as to the value of B. Direct evidence of the change in form of the B—H, or rather B-current, curve is furnished by the magnetic curve tracer.

This instrument, which was exhibited by one of us at the Edinburgh meeting of the British Association (1892), draws the magnetic curve by giving to a small mirror two component motions, one (horizonal) proportional to the magnetising current, and the other (vertical) proportional to the magnetism of the metal under examination. The metal is arranged to form a magnetic circuit which is complete except for a narrow gap between a pair of opposed poles. In this gap a wire is tightly stretched, through which a constant current passes. The wire consequently sags up or down in the gap as the magnetism of the circuit varies, and this gives movement in altitude to the mirror. At the same time, the varying magnetising current passes through another similar wire tightly stretched between the poles of another magnet. The magnetism of this second magnet is kept constant, and hence the sagging of its wire depends on the varying strength of the current which the wire carries, namely, the magnetising current of the other magnet. This gives azimuthal movement to the same mirror. A spot light reflected from the mirror to the screen consequently traces out the curve of magnetism and magnetising current. The movements are so dead-beat that with a light mirror and tightly stretched wire a magnetic cycle of double reversal may be traversed ten times or even twenty times per second without material distortion from the inertia of the working parts. The variation of magnetising current must not, however, be sudden, and to secure this a commutator is used in which a revolving boss carrying two zinc plates turns within a cylinder containing a weak solution of zinc sulphate, in which there are two other (fixed) plates of zinc. As the revolving pair of plates reverse their position between the fixed pair, the potential of a battery connected to the fixed plate becomes reversed on the revolving pair, and from them the current is taken to the magnetising coil.*

By the slow manipulation of a rheostat of any form the magnetising force may be carried throughout any desired series of changes, and the character of the corresponding process of magnetisation be studied. The instrument affords a ready means of testing the comparative magnetic quality of given samples of metal. It also allows features in the magnetising process to be examined which it would be difficult to observe in other ways. We have made a number of experiments with it, some of which may be cited as showing the application of a novel method in magnetic research, and also as bearing incidentally on points that have been already spoken of in connection with the ballistic tests.

* For diagrams and description of the magnetic curve tracer, see *The Electrician* of May 26, 1893.

PROF. A. B. W. KENNEDY'S PRESIDENTIAL ADDRESS TO THE INSTITUTION OF MECHANICAL ENGINEERS.

It is a well-known difference between engineering practice in this country and in most others that the conditions of our work seldom allow us to carry specialisation to any such great extent as is common, for instance, all over the Continent. With us, the belief that a man is "a thorough practical engineer"—whatever that may mean—is very generally taken as evidence that it is safe to ask him to do anything whatever which may be included within the vague general term "engineering." Of the extent to which this feeling is carried, as well as—I must say—of the essential truth which lies at the bottom of it, no better illustration could possibly be found than the position now held, with so much advantage to the public service, by my distinguished predecessor in this chair, Dr. Anderson. Some of us have occasion to examine continually the epitomised professional histories of engineers who wish to belong to, or be promoted in, our Institutions. It is quite noteworthy in how many cases, especially in our own Institution, a man of 35 or 40 is found to be working with great success in a line totally different from that in which he gained his first experience.

The existence in the minds of the public, who are in fact our employers, of the feeling which I have mentioned, no doubt brings us very often into temptation—temptation to undertake work or responsibility in directions where our own common-sense only, unaided by past experience, must be our guide. He is a wise man who can tell, as each opportunity presents itself, whether it is really a tide to be taken at its flood, or whether it is one in which his swimming powers will not be sufficient to carry him on to fortune, but may only leave him, and those who trust to him, still short of *terra firma* when the ebb commences. The consideration of this point has probably caused many of us more anxious moments than the actual working out of any of the knotty engineering problems which come upon us after the plunge is taken. I speak in the matter from hard enough experience, for I myself have had all too often to decide such questions, sometimes in one sense and sometimes in the other. So it happens that having served my time with marine engineers, I have had in the last 25 years to busy myself with half-a-dozen varieties of mechanical and structural work (including what I may call the academic variety during many happy years at University College) and of late years also with the newest variety of all—electrical engineering. I trust that my electrical friends—those of them, that is, who are 20 years younger than I am—will forgive me for calling electrical engineering a variety of mechanical work. I mean nothing disrespectful, of course; but even to those who are much more thoroughly electrical engineers than I can ever hope to be, but who have had the chronological misfortune, like myself, to have become engineers before technical electricity existed (if I may be allowed so to speak), I think it must always be so. To such of us, electrical work has been grafted on to mechanical; and any success we have had in the one we trace back to its foundation in our knowledge of the other. And further—although I know that in this I lay myself easily open

to an accusation of mere conservatism—I believe that even now the only really safe road to success in electrical work lies through the old routine of mechanical training, modified of course by the excellent means for studying the scientific side of the work which now exist in so many directions.

It is common on occasions like the present for the speaker to lay before the members such matters out of his own personal knowledge or research or experience as he thinks may be most generally useful to them, as some small acknowledgment of the honour which he has received at their hands in his election as their President for the year. In thinking how best I could fulfil this honourable obligation and pleasant duty it occurred to me, in connection with the train of thought which I have just put before you, that, as I happen by some chance to be the first of your Presidents who has been actively connected with electrical work, it might be of interest to you, and possibly also of use to some, if I endeavoured to put before you as clearly as I could the way in which the electrical problem of to-day in this country presents itself, when looked at from the mechanical engineer's point of view rather than from the electrician's—in other words, from your point of view and mine.

Practical electrical problems divide themselves probably into three main sections, in which electrical energy is used respectively for :—

i. Lighting.
ii. Power.
iii. Physico-chemical processes.

The third section—where energy is used for the deposition of metals, for the reduction of chemical compounds, &c.—falls outside my own knowledge. From what I know of the success with which it is being worked, I cannot doubt that it has a great future. But its problems only touch engineering very indirectly as yet, and therefore hardly come within the subject which I have prescribed to myself. In this section may be included, at least for present purposes, the application of electricity to heating. So many active and competent workers are at present engaged on this matter that it is greatly to be hoped that success may soon attend their work. Not only the difficulty of producing the heat but also that of producing it in a convenient fashion, have been overcome to a very large extent. The remaining difficulty is the purely commercial one of producing the heat sufficiently cheaply to allow of its general use. This, I am afraid, has not yet been overcome; and until it has been, electrical heating unfortunately hardly comes within our ken except for very special purposes.

Remembering that something like 95 per cent. of all the energy that goes to incandescent lamps appears only as heat, and not as light, there appears to be an ample opening here for another "thermal storage" process, at least until the present lamps are superseded by the less wasteful type which the future will doubtless reveal to us in good time.

The use of electrical energy for power, *i.e.*, for transformation into mechanical energy, is a matter which lies obviously in the closest possible connection with mechanical engineering. It divides itself broadly into three sections, viz., (1) Transmission from a distance for whatever purpose, (2) Transmission to a number of isolated points comparatively near together, as the tools in a factory, and (3) Transmission for the purposes of traction on railways or tramways.

The *transmission* comes in in every case because we have as yet no electric prime-mover analogous to a steam-engine. The electric motor pre-supposes the existence of a dynamo, which must itself be driven by some prime-mover. From the dynamo to the motor, whether near or far apart, there must always be transmission of electrical energy. In a recent extraordinary aberration it seems to have been discovered that there was some positive advantage in using steam-engine, dynamo and motor all in one place to do work hitherto done by the steam-engine alone. This wonderful locomotive, however, forms, and no doubt will continue to form, a class by itself!

As to the transmission of power from a distance I shall not say anything, mainly because I could say nothing so well as it has quite lately been said by Prof. Unwin in his Howard Lectures. The whole matter is there discussed with so unusual a combination of impartiality, scientific accuracy, and mechanical common sense as to make the lectures, short as they are, into one of the most important contributions to engineering literature which have appeared in this country for a very long time. In particular, one cannot help being struck with the judicial way in which the author has kept clear of the fatal fascination which this matter possesses over many minds otherwise sane—a fascination which in some cases goes so far that one finds the whole matter discussed, perhaps unconsciously, on the basis that it is a positive advantage to transmit power from the longest possible distance! There are several towns in the United Kingdom where the use of water power for the purpose of electric lighting will have some day to be seriously considered, but I hardly think that beyond these the present generation is likely to see any great development in this direction at home. In other parts of the world the conditions are, of course, very different, and English engineers who wish to secure their share of work in this direction will rather have to study it beyond the limits of their own country.

The question of driving the tools in a factory by electric motors instead of through countershafting is one which has recently come to the front. The carrying out of such work is obviously purely a matter of mechanical engineering. Its advisability in any particular case is partly a question of economy and partly one of convenience, and is undoubtedly dependent on the conditions of each particular case. I have found from information very kindly given me by several large engineering firms, that the actual cost to them of power, including coal, stores, wages and depreciation, generally lies between 2 and 5 per cent. of their total costs.

In any given factory running on the ordinary system there is a large continuous waste of power due to the running of the whole shafting, no matter how many or how few machines are at work. Under such conditions the waste work in shafts and belts may well be even 25 per cent. of the average useful work, and the distribution of total work may be approximately :—

	H.P.
Average useful work	100
Wasted in belts and shafting	25
Wasted in engine friction, the engine being supposed large enough to give 150 H.P. at tools as a maximum (at about 10 per cent of max. H.P.)	20
	145

Now, if the machines in such a case were driven by separate motors, each having an electrical efficiency of 88 per cent., and these motors worked from a dynamo having an efficiency of 92 per cent. (both of which are high figures for ordinary work at two-thirds output), the figures would stand as follows :—

	H.P.
Average useful work	100
Wasted in motors and dynamo	24
Wasted in leads (say 2 per cent.)	2
Wasted in engine friction (as above)	20
	146

It will seen that the two sets of figures are practically the same as to amount of power required. As the electrical efficiencies which I have assumed are not likely to be exceeded, I think it may be said that there is no saving to be obtained in horse-power, and none, therefore, in any of the items of costs directly dependent on horse-power in cases where the power wasted in shafting and belts does not exceed 25 per cent. of the whole average useful power. This is a ratio which any engineer can most readily obtain for himself if he is not afflicted with that sense of the insuperable difficulty of making any simple and exact experiment which still remains one of the obscure diseases of our profession. I have no doubt cases can be found where the waste in large factories with very widely distributed power is very much greater than the proportion assumed, and in such cases no doubt a saving in power costs would occur.

But at the root of the matter there probably lies one ultimate determining point, far too often neglected in such calculations as I have just been making. This point is, of course, the real absolute saving to be made as distinguished from the proportionate saving. It is of little use to show an engineer that he can make even 20 per cent. saving in some one item of expenditure if that whole item only represents 3 or 4 per cent. of his costs, and if at the same time he has to expend a considerable amount of capital in making the change. One does not make important and expensive changes, especially changes whose result is by no means very certainly to be predicted, to bring about an estimated saving of half of 1 per cent. in one's total expenditure. I fear that this is a matter which may prove a more serious difficulty in the way of the success of the great Niagara scheme than any of those described by Prof. Forbes. In reference to our present point, it will prove sufficient to prevent the adoption of isolated motors in engineers' works in all cases except the waste in belt and shaft transmission is exceptionally great, or where for other reasons electrical driving *per se* is desirable.

But the whole matter is certainly not concluded either one way or the other by this single consideration. There can be no doubt, on the one hand, of the practical convenience of getting rid of the huge mass of shafting, gearing, and belting which fills up the upper half of many engineers' shops, although it is difficult to fix any money value for this advantage. There is no doubt also that a properly-arranged motor may give a much larger range of speed to each tool than can be readily obtained in the ordinary way, and will thus enable more and better work to be got out of it with skilful management. Were it not that such magnificent work has often been turned out in this country from such dirty and apparently disorderly shops, I should also say that it was self-evident that every change which improved the general orderliness and tidiness of the shop must—reacting upon the men employed—improve the output both in quantity and quality. Under the actual circumstances one hesitates

Digitized by Google

to be dogmatic on this point, but I incline to believe that it is true, and that the good work to which I have referred has been turned out in despite of its environment, and has been due to exceptional excellence in workmen or managers or both, and that with the same men it might even have been still better under better working conditions.

On the other hand, it has to be pointed out that the cost of dynamo, leads and motors, is very greatly indeed in excess of the cost of shafting in almost every case. It is also hardly certain as yet how the costs of attendance, lubrication, renewals and repairs to the electrical plant compare with the similar costs in the case of shafts and belting. Probably, on the whole, they would be less, but no satisfactory data on this point exist.

There arise two special cases which should be mentioned. In cases where electrical energy can be obtained from public mains the comparison is quite different. The working of the printing machines, for instance, in the office of the *Pall Mall Gazette*, is carried out electrically, the current being derived from the mains of the Charing Cross and Strand Electric Supply Company. The works in this case get rid of all costs of engines and boilers with all their many inconveniences, and also gain in space most of the room occupied by their old plant. Moreover, they have a better security against breakdown than they could otherwise very well afford to have without most costly duplication of plant. The matter then becomes simply one in which increased space, convenience and security are to be balanced against increased cost, and each case has to be considered on its own merits. At present it is not very certain how the engineer supplying the electric energy ought to look at such a case. His chief business is, and will be, to supply energy for lighting purposes. As is sufficiently well known, the demand for lighting energy varies enormously throughout the twenty-four hours, so that in fact, a plant which is giving 2,500 H.P. for a couple of hours every day, and which of course must be large enough for this purpose, leaving still machines in reserve, will only be giving an average of 350-H.P. taken over the whole week, and not even half this for many hours every day and night. It is, of course, very desirable to increase the load during the hours of light load, and, if this could only be done without also increasing its present maximum, that is, without necessitating increase of plant, engineers could afford to sell the additional energy at a very low rate indeed. Unfortunately the condition I have mentioned is impossible. There will always come hours when, through fog or other special causes, the power load will coincide in time with the lighting load. And even if this were to happen only once or twice a year, the engineer must none the less provide plant for it and keep the plant ready. The case is not met by differential charges at different hours. The plant must be provided all the same, and the additional outlay will not be met by the extra payment for a few hours' work per annum. It may, however, very well be met by the value of the additional work done on 360 days out of 365 at times when otherwise nothing would be done. This point I shall deal with later on.

A second special case occurs when the cost of power forms a very large instead of a very small proportion of the whole running costs of the works, and no doubt in several industries this is the case to a very much greater extent than in engineering works.

I will ask you particularly to notice that in the case where electrical driving supersedes belts, the work is not done any less directly than before. Between the engine and the tool there stand, in the one case belts and pulleys and shafts twice or thrice repeated, and in the other case dynamo and leads and motor, with or without a small belt from motor or machine. It is quite possible that the actual mechanical efficiency of the belts is greater than that of the two electrical machines and the leads between them. But in the case of the shafts and belts the losses are continually going on whether or not useful work is being done, whereas there are no losses in the motors unless they are actually running and driving tools. This brings the total losses equal in the case I have supposed and in other cases may make the electrical method more economical. But the change is merely a substitution of one indirect method for another equally indirect method.

In the third great case of electric transmission of power, for the purpose, namely, of driving trains or tramcars, we have a state of affairs which is entirely different, and which, I am afraid, is by no means so favourable to the use of electricity as is sometimes supposed. In the case of a train drawn by an engine in the usual way, we have the whole of the net power of the engine, exclusive of that spent in internal friction and in actually hauling itself along—say 80 per cent. of the gross indicated horse-power—available for pulling its load along the line. In the case of an electric railway we have truly a somewhat lighter locomotive to be moved, but against this advantage and the fact that a stationary engine can have a greater economy than a locomotive, we have the uncomfortable state of affairs that only some 35 per cent. of the whole indicated horse-power, as against 80 per cent., is available for the useful work of pulling the train. It seems, moreover, hardly likely that this low percentage will be much increased. The cause of the loss is, of course, the extreme indirectness of the process, that is, the very great number of transformations through which the energy has to pass, in each of which there is always a loss. We may take the figures approximately somewhat thus, always remembering that the average power would be less, probably very much less, than three-quarters of the full power of the plant at work :—

	Per cent.
Mechanical efficiency of engine	85
Efficiency of belt-driving (if employed)	94
Efficiency of dynamo	90
Efficiency of line	85
Efficiency of motors	85
Efficiency of gearing on locomotives	75
Total efficiency	39

From this is to be deducted say 10 per cent. for driving the locomotive, leaving 35 per cent. for pulling the train.

I think it may fairly be said, that, to a mechanical engineer, the greatest enemy to all economy is frequency of transformation, and that it is, or ought to be, a fundamental rule in all engineering work that every unnecessary transformation, whether mechanical or electrical, should be avoided.

Notwithstanding this terrible drawback, the absence of foul gases is of such overwhelming great importance in some cases that the working of the City and South London Line has only been possible at all because electricity has been employed instead of steam. This, of course, is a case where mere economy of power was not the only or even the most essential thing sought for. In the Liverpool Overhead Railway also the same conditions of the case rendered the use of steam locomotives impossible, as the line runs along a route on which they are prohibited.

The case of tram lines along streets differs altogether from that of an underground or indeed any other railway. Here the steam engine with its boiler is a bulky and objectionable affair, very apt to cause smoke and other disagreeables, and very unsuitable for trains which consist of one vehicle only, weighing less than its locomotive would have to weigh. I have often wondered why the Serpollet boiler and engine have not been introduced for tram work. They take so little space that they might very possibly be put on the car itself (the car being made reversible as at Manchester), but I suppose some difficulties have been found ; at any rate the proposal has not been made, so far as I know. But apart from this, and not forgetting the steam cars which are actually at work in certain places in the North, there is probably no form of steam car which would be generally endured by the public. Here again, therefore, electricity would appear to come in regardless of cost, in the same way as with the underground railway, although for another reason. But here we are met at once with the mechanical difficulty (not existing of course, in the tunnel or on the overhead railway) of getting the current to the motors on the car. In America, the knot is cut, rather than untied, by the use of overhead wires, and in country places it is probable that this may be here the best solution of the problem. But in our cities, where the bulk of the tramway traffic of the country is really carried on, I am still conservative enough to think and also to hope that this is impossible. Without forgetting the much-quoted case of Buda-Pest, therefore, I fear that the introduction of electricity for car-driving in this country will still wait until a practicable underground system has been devised. Meanwhile it is being hard pressed by its rivals—cable and compressed gas. Of the two I think the latter, although the younger, is far the more formidable. It has the advantage of being even more direct than a steam-engine (the boiler being absent) ; it can be applied to each individual car even more easily than an electrical motor, and it enables the car to run freely on ordinary lines without their reconstruction, and without any mains either above or below ground. It has, as yet, had but short trial, but what I have seen of it makes me sanguine as to its ultimate possibilities.

Before speaking more particularly about the mechanical aspect of electric lighting problems, I feel bound to touch upon a matter which arises directly out of the question of supplying electric energy for power and for light concurrently, to which I have just drawn attention. It is a favourite bit of cheap criticism indulged in by those who have not to supply energy on a large scale, at the expense of those who have, that the former class of folk show their ignorance of their own work and interests by neglecting to obtain that enormous demand for motive power which would come on them if only they reduced their prices low enough. The criticism is really as absurd as that other which censures the gas companies because they do not supply heating gas at a few pence per 1,000ft., which, apparently, they would be perfectly able to do if only they knew their own business half as well as their critics do ! In both cases the criticism is mere words, "signifying nothing." We have simply to remember the fact that the mere possibility of driving something by electricity does not of itself create the things that want to be driven. There are isolated districts in London—Clerkenwell, for instance, and the neighbourhood of Fleet-street—in which there is a considerable

Digitized by Google

amount of power of a kind which might be furnished electrically if the cost were made sufficiently low. In most parts, however, the whole energy expended in doing mechanical work is but a very small percentage indeed of the energy required for light, and it would not be increased in the least even if it were supplied for nothing. When the inhabitants of Mayfair and Kensington, for instance—to take these districts only as typical of many others—take to brushing their boots, washing their faces, and serving their meals by electricity, a demand will have arisen which may perhaps be fostered into something worth considering. Until this happy state of affairs comes about, I fear that the demand for motive power in English residential and semi-residential districts must remain a factor practically negligible in the calculations of the engineer.

Whether in a purely manufacturing district it may ever be found to pay to put down a central power station and transmit power to factories, each of which would replace its steam-engine and boiler by an electric motor, is a question about which there is a good deal to be said on both sides. I have already indicated the lines along which I believe this matter will settle itself.

(To be continued.)

SECOND REPORT OF THE ROYAL COMMISSION ON ELECTRICAL COMMUNICATION WITH LIGHTHOUSES AND LIGHT-VESSELS.

[Abstract.]

Since the issue of our first report* we have made a further tour of inspection of lighthouses and light-vessels. On July 10, 1893, we assembled at Glengariff, Bantry Bay. On the following morning we embarked on board the steamer "Moya," which was placed at out disposal by the Commissioners of Irish Lights, and inspected the Bull Rock and the Fastnet. Leaving the "Moya" at Baltimore, we proceeded to Cork, and thence to Kingstown, where we embarked on board H.M.S. "Enchantress." On the morning of July 13 we proceeded to the Isle of Man, landed at the Chicken Rock Lighthouse, and, passing Langness Lighthouse and the Bahama Bank light-vessel, anchored in Ramsey Bay. On the following day we crossed from the Isle of Man to Bangor, county Down, passing the South Rock and Skulmartin Rock Light-vessels and Mew Island Lighthouse. On July 15th we proceeded to Lamlash, landing on the way at the Maidens and Ailsa Craig Lighthouses. After having visited Pladda Island Lighthouse, we landed on July 17th on Sanda Island and Rathlin Island, inspecting the lighthouses on those two islands, and anchored for the night in Lough Foyle. From Lough Foyle we proceeded to Oban, after having inspected the lighthouse on Inishtrahull Island, and from Oban we steamed through the Sound of Sleat to Stornoway. Returning to the mainland, we anchored at Loch Inver, and visited the Ru Stoer Lighthouse, and on July 24th we left Loch Inver for Longhope in the Orkney Islands, whence we paid a visit to the Cantick Lighthouse and to the Look-out Station of the Commissioners of Northern L ghthouses on Brough Ness, opposite to the Pentland Skerries Lighthouses. On July 26th we inspected Stroma and disembarked at Scrabster. Then proceeding south by train to Seahouses, we embarked on board the Trinity House steamer "Argus," which conveyed us round the Farn Islands. The tour of inspection ended with the visit to the lighthouses on those islands. We reassembled in London in September, and have since held several meetings.

Although the general question of signalling had not been directly referred to us, it appeared to be so intimately connected with the subject of electrical communication that we felt ourselves justified in considering it, and in our First Report we stated that in cases "where the distance from the shore is not great, an improved system of distress-signals (distinct from the usual fog-signals) might, both at rock stations and on light-vessels, prove an effective temporary substitute for the more costly expedient of electrical communication." This view has been confirmed by the experience which we gained during our last tour of inspection, and we are now prepared to go further and recommend that the General Lighthouse Authorities should be invited to consider the subject with the view of instituting a universal system of visual and sound signals at all the various light stations on the coasts of Great Britain and Ireland.

A member of the Commission, Sir Edward Birkbeck, having occasion last spring to visit the United States of America, we requested him to take the opportunity of inquiring into the systems of coast communication in force in Canada and the United States. On his return to this country, Sir Edward Birkbeck, submitted to us a report, a copy of which will be found in the Appendix. From that report it will be seen that, while both Canada and the United States possess an efficient system of electrical communication round their coasts, none of the light-vessels belonging to those countries had been electrically connected with the mainland.

We have received and considered particulars of a number of inventions for effecting electrical communication between light-vessels and the shore, but none of these are, in our opinion, preferable to the "sunk" system, which is now being applied to the Goodwin (North Sand Head) and Kentish Knock Light-vessels.

We have again to express our obligations to the Admiralty for the loan of H.M.S. "Enchantress," and to the Trinity House, the Commissioners of Irish Lights, and the Commissioners of Northern Lighthouses for the assistance which they have rendered to us.

* See *The Electrician*, Vol. XXX., p. 396, February 3, 1893.

Recommendations.

We recommend that electrical communication by aërial wires be established without delay between the telegraphic system of the country and the following shore lighthouses and lighthouse stations:—

Name of Lighthouse.	To be connected by telephone with	Estimated cost (approximate).
Falmouth Harbour	Portscatho C.G.S.	£160
South Point	Whitburn C.G.S.	100
Montrose (Scurdy Ness)	Usan C.G.S.	85
Covesea Skerries	Lossiemouth P.O.	83
Tarbet Ness	Portmahomack P.O.	55†
Look-out Station at Brough Ness for Pentland Skerries Lighthouses.	St. Margaret's Hope P.O.	233
Fair Isle (North end)	Fair Isle P.O.	128
Sumburgh Head (Shetland Islands)	Sumburgh P.O.	65
Cape Wrath	Durness P.O.	20†
Ru Stoer	Stoer P.O.	20†
Rhynns of Islay (Oversay Island)	Bruichladdich P.O.	330
Turnberry	Maidens P.O.	48
St. Bees	St. Bees P.O.	76†
Langness	Castletown P.O.	103
Menai	Beaumaris P.O., & Life-boat Coxswain's house at Penmon.	72
South Stack	Holyhead C.G.S.	15
Galley Head	Dunny Cove C.G.S.	150
Loop Head Kilcradan Point	Carrigaholt P.O.	61†
	Total	£1,804

† If Admiralty wire is used.

It is with regret that we have decided to confine our recommendations in this Report to Shore Lighthouses, but, until more has been done towards effecting the connection of those light-vessels and lighthouses, which were selected in our First Report as having the strongest claims to immediate attention, we hesitate to add to the list of the light-vessels and island and rock lighthouses, with which we consider that electrical communication should be established.

(Signed) Mount-Edgcumbe (Chairman); Henry Lyle Mulholland; Edward Birkbeck; F. L. M'Clintock; G. S. Nares; W. H. Preece; J. C. Lamb; John A. Kempe; R. Munro-Ferguson; Ernest G. Moggridge (Secretary).

APPENDIX.

Report of Sir Edward Birkbeck on the System of Coast Communication in Canada and the United States.

I have the honour to report that, in accordance with the desire expressed by the Royal Commission on Electrical Communication with Lighthouses, &c., at their meeting held on March 20th, I proceeded, after the termination of my official visit to Chicago, to obtain, both by inquiry and by personal inspection, some information in regard to the telegraphic and telephonic system of coast communication now in force on certain portions of the coast of Canada and the United States. The request addressed by the Secretary of the Royal Commission to the Colonial and Foreign Offices that those departments should ask that facilities might be given to me by the Governments of the Dominion of Canada and of the United States secured for me great assistance in my work of investigation.

Canada.

On my arrival at Ottawa Mr. William Smith, Deputy Minister of Marine, give me a most exhaustive explanation of the working of the coast telegraphic system of the Dominion. He was desirous that I should visit the life-saving station on Sable Island, but thought it still more important that I should inspect a first-class lighthouse signal station commanding, during the navigation season, the largest amount of passing shipping.

The s.s. "La Canadienne" was, therefore, ordered to meet me at Dalhousie on the coast of New Brunswick, and to convey me to any portions of the coast that I desired to visit. I accordingly proceeded from that place early on the morning of May 25th in a north-easterly direction up the Gulf of St. Lawrence, passing the lighthouse signal stations on Macquereau Point and Cape Despair, and landing the same evening at Cape Rosier, a first-class lighthouse signal station. This lighthouse, which was established in 1858, is situated on a low cliff, and has a fixed white light 136ft. above high-water mark with a range of visibility of 17 miles. The position is one of great importance for a signal station, and a large amount of shipping passes within signalling distance, bound either to or from Europe, Nova Scotia, or the United States, including in the summer season, steamers proceeding through the straits of Belle Isle to Quebec and Montreal. The lighthouse keeper at this station receives 800 dollars per annum, and has to pay his assistant out of this sum. He is allowed to employ more than one assistant, if he desires, but he must do so at his own cost. During the time the navigation is open—generally from about April 1st to December 10th or 20th—the keeper and his assistant are responsible for the performance of the following duties:—(1) Lighting and cleaning the lamps. (2) Managing the boiler and engine for sounding the steam horn. (3) Painting the inside and outside of the lighthouse.

Digitized by Google

(4) Taking entire charge of the telegraph (Morse) instrument. (5) Reporting to Quebec twice a day the state of the weather. (6) Reporting all ships passing the station. (7) Telegraphing for tugs to assist disabled vessels. (8) Forwarding any public or private telegrams which may be handed in.

Private messages handed in can be paid for either by the sender or receiver, and at some of the signal stations a very considerable amount of telegraph business is transacted during the summer months for trade purposes.

At night we steamed passed Fame Point Lighthouse Signal Station, and proceeded to the Island of Anticosti, situated 65 miles from the mainland of the Province of Quebec, 107 miles from Newfoundland and 40 miles from the coast of Labrador. The island is connected by cable with the mainland near Cape Rosier, and also with the coast of Labrador. I landed at West Point Lighthouse Signal Station at 4 a.m. on May 26th, and inspected that lighthouse, which was established in 1858 and is situated on low land. It is furnished with a fixed white light 106ft. above high water-mark, visible 15 miles. This is one of four first-class lighthouse signal stations, all situated on the south-west coast of the island. They are much needed on this dangerous coast, and are of great importance both as signal stations and for furnishing reports regarding the weather, and also regarding the state of the ice at the beginning and end of the navigation season. The lighthouse keeper at West Point has two assistants, both paid by himself, with duties similar to those at Cape Rosier Lighthouse, except that a large gun is used in foggy weather instead of a foghorn. The signal station at Heath Point Lighthouse is the most important of the four for signalling purposes, but on inspecting the return of commercial messages handed in during the year at West Point Station, I found numerous entries proving that, even at that most out-of-the-way-station, coast communication is of importance to the trading community.

A westerly gale, accompanied with snow and rain, made it impracticable to land at the East Cape Lighthouse Signal Station; but I was informed that the arrangements there are similar to those at the West Point Station.

The Canadian Government have established a complete and thorough system of telegraphic coast communication, and have also provided cable communication with every island of importance, with the exception of Sable Island,* which will be connected in due course. The telegraphic, instead of the telephonic, system has been adopted on account of the number of commercial messages which have to be sent, and the long distance which the messages have to be transmitted.

Many of the Canadian light-vessels have to be moved from their stations during the winter on account of the ice, and the question of cable communication with them has not been taken in hand.

United States.

On Wednesday, May 30th, I called on Capt. Charles A. Abbey, Inspector of Life-saving Stations for the United States, at his office in New York. Capt. Abbey, who had been instructed by the Government at Washington to render me assistance during my visit, gave me all possible information respecting the telephonic service at the life-saving stations, as well as regarding the life-saving service itself.

In accordance with the suggestion of the United States Government, which I received through Sir Julian Pauncefote, I proceeded on the following morning with Capt. Abbey to the coast of New Jersey State. We landed near Sandy Hook, and went thence by rail to Seabright Life-saving Station.

It is important to observe that, with the exception of the ten stations on the Pacific coast, and those round the shores of the great lakes during the season of open navigation, the staff at the life-saving stations are, from May 1st to September 1st, all disbanded, the keeper alone being left in charge to work the telephone.

Orders had, however, been given by the United States Government to summon the surfmen at Seabright Station, in order that I might see everything in full working order. I found this first-class station thoroughly organised and fully equipped in every detail. A very commanding place of look-out is provided on the roof, from which vessels in distress can be seen for a considerable distance, and telephonic communication can be effected with any one of the stations on the coast within 70 miles, by means of switches. The keepers were loud in their praises of the advantages of the system for life-saving purposes, and stated that in the winter, distant stations are often warned in advance to be prepared for an emergency.

The wire is carried on iron poles from the stations to the nearest system of wires—generally following the coast line—and where telegraph poles are not already available, iron ones are erected in close proximity to the shore, and to the life-saving stations on either side. The cost of running a wire from station to station is on an average (according to information given me by the district superintendent of telephones), say 75 dollars a mile, without the instruments. Great importance is attached to the principle of running the wires direct from station to station, and not using existing lines many miles inland, and then returning to the coast, as has been done in many cases in England, thus making it necessary to call up the postmaster at night.

The United States Government allow the station telephones to be used by the general public in cases where there is no telegraph office near, and messages are forwarded by the station keepers to the telegraph offices, payment being collected from the receivers of the messages.

Among other duties performed by the surfmen when on patrol in out-of-the-way districts is carrying letters in order to expedite their delivery.

I visited three other stations, viz. (1) Monmouth Beach, (2) Long Branch, (3) Deal. The arrangements, so far as coast communication is concerned, at these and at all the other stations are very similar to those at Seabright, which I have described.

* See *The Electrician*, Vol. XXVI., p. 244, December 26th, 1890.

I may add that the system of telephonic communication in connection with the life-saving service on the shores of the great lakes during the navigation season is of an equally efficient character, and the necessity for this is apparent when the extent of the lake trade is considered, the annual import and export tonnage for the port of Chicago alone, on Lake Michigan, being larger than that of New York. No cable communication from the shore to light-vessels has yet been established; but wires are laid to the electric buoys wherever they are placed, no ships being allowed to anchor near them. I have, however, reason to believe that the United States Government are about to consider the desirability of cable communication between the mainland and some of the light-vessels and rock and island lighthouses, with none of which does communication at present exist for life-saving purposes.

In conclusion, I would remark that the Canadian telegraphic coast communication arrangements appear to me to be carried out in a most efficient manner, and to be of great use to the Government and general public, and considering the many duties which the lighthouse keepers have to perform with so small a staff to assist them, it was most striking to see the great interest they take in their extra work of telegraphy and how cheerfully they perform it.

These facts lead me to venture to think that the Royal Commission will have no hesitation in recommending that more lighthouses be telephonically connected with the Post Office system on certain parts of our coasts.

From the inquiries I made in the United States, at the Government establishment at the World's Fair under Lieutenant Charles H. McLellan, from the information I gained from Capt. Abbey, and from my inspection of the stations on the New Jersey coast, to which I have referred, I am convinced that the system of telephonic coast communication now in force in the United States is a very admirable one, and I am of opinion that the maximum of efficiency would be secured if in due course the system of direct lines running along the coast could be adopted in this country, instead of the zigzag system of communication through inland post offices, which necessarily at night involves loss of time, a matter in some cases of vital importance.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, April 27th.

PHYSICAL SOCIETY.

5 p.m. The following Papers will be read:—(1) "The Mechanism of Electrical Conduction," by Dr. C. V. Burton. (2) "A Graphic Method of Constructing the Curves of Current in Electro-Magnets and Transformers," by Major Hippisley, R.E. (3) "The Design and Winding of Alternate Current Electro-Magnets," by Prof. S. P. Thompson, F.R.S.

JUNIOR ENGINEERING SOCIETY.

7:30 p.m. Visit to the new Mechanical and Electrical Engineering Laboratories at University College.

MONDAY, April 30th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture: "Typewriting Machines," by H. C. Jenkins.

TUESDAY, May 1st.

ROYAL INSTITUTION.

5 p.m. Annual Meeting.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read:—"The Manufacture of Briquette Fuel," by W. Colquhoun.

WEDNESDAY, May 2nd.

IRON AND STEEL INSTITUTE.

10:30 a.m. General Meeting of Members at 25, Great George-street. Presidential Address.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. The following Paper will be read:—"Nickel," by A. G. Charleton.

THURSDAY, May 3rd.

IRON AND STEEL INSTITUTE.

10:30 a.m. General Meeting at 25, Great George-street.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Solid and Liquid States of Matter," by Prof. Dewar, F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Second "James Forrest" Lecture:—"The Relation of Mathematics to Engineering," by Dr. John Hopkinson, F.R.S.

FRIDAY, May 4th.

LONDON CHAMBER OF COMMERCE.

2:30 p.m. Meeting of the Electrical Trade Section at Botolph House, Eastcheap, to consider the Locomotive Acts in relation to the Traction industry.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting at 28, Victoria-street. Paper to be read: "A Description of the Electrical Type-Printing Instruments as used by the Exchange Telegraph Company," by F. Digby Latimer.

SATURDAY, May 5th.

ROYAL INSTITUTION.

3 p.m. Tyndall Lecture:—"Colour Vision," by Capt. Abney, F.R.S.

SPECIAL NOTICE.

The present number of "THE ELECTRICIAN" completes Vol. XXXII. With next weeks Number will be issued (Gratis) the Index to the Volume.

READY NEXT WEEK.

Volume XXXII. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad carriage extra.

Cases for binding Volume XXXII., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

STATUTORY PROTECTION AGAINST ACTIONS FOR NUISANCE.

In February, 1893, we reported the case of "National Telephone Company *v.* Graff Baker," in which Mr. Justice KEKEWICH held that, although the working of the Leeds Tramway constituted a nuisance to the Telephone Company, yet the fact that the tramway was constructed and worked by electricity under statutory powers precluded the Telephone Company from obtaining the redress which he would otherwise have granted them. Last week we reported another decision of the same judge in the case "Meux's Brewery Company *v.* The City of London Electric Light Company," where the plaintiffs were awarded damages for the nuisance caused by noise and vibration due to the machinery at the Bankside Station of the defendants, whose statutory powers were pleaded in vain. Since these two judgments might at first sight appear to be at variance, it may be useful to make a few remarks upon them.

The question of how far acts, injurious to individuals, but done in pursuance of statutory powers, are exempted from the ordinary law of nuisance, has, like most other important legal doctrines been the subject of numerous judicial decisions. Two of these, both pronounced by the House of Lords, may be quoted as illustrations of what kind of powers will, and what will not secure such immunity, assuming in both cases that the operations complained of are conducted with proper care, and in the manner sanctioned by the statute. In "Hammersmith and City Railway Company *v.* Brand," decided

Digitized by Google

1869, it was held that the Railway Company, having constructed their line according to the route laid down by Parliament, were under no liability for any nuisance due to vibration caused by running their trains upon this line in the absence of negligence in the method of working. In the case of "Metropolitan Asylum Managers *v.* Hill," decided in 1881, complaints were made of the injury caused to neighbouring residents by the erection of a small-pox hospital at Hampstead. The Asylum Managers were authorised by statute to build the hospital, and acquire land for the purpose without restriction as to locality. It was almost impracticable to build it anywhere, without some risk of causing depreciation to adjoining property, having regard to the fact that it must be easily accessible for the London poor. Yet it was held that the site chosen not having been expressly approved by Parliament, the Managers were liable to be restrained by injunction from continuing to use the hospital for small-pox patients. In the Leeds case, Mr. Justice KEKEWICH followed the first of these two decisions of the House of Lords, holding that the tramway, having like a railway a route defined by Parliament, no one could complain of electricity being employed with reasonable care for driving the trams, since that mode of traction was expressly authorised by the Company's statutory powers. The Telephone Company, as is well known, are protected by special clauses in the Electric Lighting Provisional Orders; but apart from any special protection of this kind, electric lighting mains would, no doubt, be held entitled to the same immunity as a tramway line. Generating stations, however, stand on a different footing. The Electric Lighting Acts authorise supply companies "to acquire such lands by agreement. . . . construct such works thereon. . . . and do all such acts and things as may be necessary and incidental to their supply," but no compulsory powers are granted in respect of any particular site, the companies being left to select any they can obtain suitable for the purpose, subject to the ordinary rules of common law as regards any nuisance they may cause. The distinction between these two kinds of statutory powers is clearly put in the judgment of Lord HALSBURY in the House of Lords in a case of the "London and Brighton Railway Company *v.* Truman," where he speaks of the Hampstead case as follows: "Broadly stated, the distinction taken amounted to this, that a small-pox hospital might be built and maintained if it could be done without creating a nuisance, whereas the Railway Acts were assumed to establish the proposition that a railway might be made and used whether a nuisance were created or not." Electric Lighting Provisional Orders contain the following clause, which emphasises this distinction: "Nothing in this Order shall exonerate the undertakers from indictment, action, or other proceedings for nuisance, in the event of any nuisance being caused by them." This clause does not, in fact, add anything to the liability of the undertakers, being nothing more than a warning against an erroneous assumption that the Order gives wider powers or greater protection than is expressly stated therein.

Counsel for the City of London Company, in the recent case, failed to satisfy Mr. Justice KEKEWICH that the statutory powers possessed by his clients differed in kind from those of the Hospital in the Hampstead case, and, consequently, their operations, notwithstanding due care in conducting them, were held amenable to the ordinary law. It is noticeable, however, that on the ground of public convenience the Judge refused to grant the injunction asked for by the plaintiffs, but exercised his discretionary power of awarding damages instead.

REVIEWS.

The Inventions, Researches and Writings of Nikola Tesla. By THOMAS C. MARTIN. (New York: Offices of the *Electrical Engineer.* 1894.)

Not only the interest of the electrical profession and of the scientific world, but also that of the general public, both here and in every part of the civilised world, has been keenly excited by the brilliant researches and the ingenious experiments of Nikola Tesla. Scientists everywhere have been charmed, and the outside world has been dazzled, besides being misled by the untimely and illogical interpretations which the general Press has put upon Tesla's researches. It is not to Tesla that the blame is due for having deluded the public into believing that the present systems of electric lighting are on the eve of annihilation, and that in a matter of a few months, or even less, the soft refulgence of "light without heat" will spread itself over whole cities. The blame lies mainly, if not entirely, with those incompetent interpreters who have rushed into print with a garbled and unscientific yarn, based upon misapprehension. Tesla, the scientist, with a prophetic eye capable of gauging the possibilities of the future, has been mistaken by these journalists for the practical man of business with a cut-and-dried system of electric lighting up his sleeve. Everyone, therefore, must welcome the appearance of a reliable account of Tesla's researches, in the compact and readable form in which it now lies before us. It is true that the whole of these researches has been already published in the electrical Press, and is available in that form to anyone. But those who have tried it know the difference between hunting out researches in several volumes of a heterogeneous collection of British and foreign journals and reading a carefully-compiled account of those researches in a handy book. Most of Tesla's work has been done in America, and the publication of it has had priority in the American electrical Press. Into no better hands, therefore, could the compilation of the work before us have fallen than into those of the editor of our American contemporary, the *Electrical Engineer* of New York.

But Mr. Martin's book is something more than a reprint of Papers already published. It commences with a short but interesting biographical sketch; and it is interspersed with several expository chapters, which will be valued by the reader who has not the time to study the detailed accounts of the researches given by Tesla in his lectures and Papers. The work consists of nearly 500 pages, divided into four parts, and is in one volume. Part I. is devoted to Polyphase Currents, and fills 113 pages. Commencing with Tesla's earliest work on alternate currents, the author traces, in the course of some 24 chapters, the evolution of the polyphase systems and of the rotary magnetic field generators, transformers and motors associated with Tesla's name. This part contains some useful account of Tesla's patents and scientific Papers on this subject. We may remark that in this part the researches are in touch with existing electrical engineering practice in a way that they are not in the succeeding parts. It is not in his researches upon electric lighting so much as in his inventions and patents in the transmission of power that Tesla has influenced electrical engineering of the present day. Part II. deals with the "Tesla Effects with High Frequency and High Potential Currents," and, in the course of eight chapters, covers the ground of the Tesla lectures upon his system of lighting by alternating electrostatic fields. The commencing chapter is a very useful *résumé* of the ground thus covered, under the title of the "Scope of the Tesla Lectures." The lectures at the Royal Institution, London, and at New York, Philadelphia and St. Louis, are printed practically, if not entirely, *in extenso.* The compiler has not, we feel sure, adopted this course without having some good reason for doing so. But we cannot refrain from commenting upon the large amount of repetition which it has involved. There is not, about Tesla's researches, that continuity and logical sequence which we look for in the work of our best men of science, and the scope of Mr. Tesla's fascinating lectures in London was pretty much the same as the scope of his no less attractive lectures in America. If it had been the case that in the latter we had the successive steps in

Digitized by Google

a line of research initiated in the former, the omission of one or even of part of one lecture might have proved fatal to the clear statement of what it is that Tesla has really done. But this is by no means the case, and we are at a loss to see why all these lectures should have been reprinted so fully. With regard to the substance of these lectures, we must warn the reader against giving it the popular interpretation. In the brilliant experiments on lighting by alternating electrostatic fields—although far from brilliant in regard to the amount of light evolved by the process—we *may* have the germ of a method of practical illumination in the unmeasured future. But those who know the amount of power that must be expended in the generating plant in order to produce these effects, and have compared this power with the net result in useful light, can hardly be in a hopeful state of mind as regards the present practical value of producing light in this way. "Light without heat" is the desideratum, but a little light in one part of the circuit and a lot of heat in another part of the circuit can scarcely be considered to attain unto it. Part III. consists of nine chapters, devoted to some discussion of Tesla's miscellaneous inventions and writings. Of the inventions described in this part we may notice a method of obtaining direct from alternate currents—the dear desire of the "alternate-current man"; condensers with plates in oil; an electrolytic registering meter; thermo-magnetic motors and pyro-magnetic generators, interesting mainly on account of the inherent inferiority of these methods to better known methods of obtaining power; a direct-current arc-lighting system; and improvements in unipolar generators. Part IV. is in the form of an Appendix, and concludes the work with two chapters, one on Tesla's personal exhibit at the Chicago Exhibition, and the other on the quite recently-invented mechanical and electrical oscillator, in which a reciprocating alternator coil is fixed to the rapidly reciprocating piston of an engine.

Throughout the book the various sections are illustrated by numerous well-chosen diagrams and pictures, and there is an artistic portrait of Tesla on the frontispiece. Altogether, this work is a credit to the compiler and author, and we have much enjoyed its perusal.

Erläuterungen zu den Vorsichtsbedingungen für Elektrische Licht- und Kraft-Anlagen des Verbandes Deutscher Privat-Feuerversicherungs-Gesellschaften. By Dr. OSCAR MAY. (Leipzig: F. W. V. Biedermann.)

The fire-risk rules drawn up by Dr. Oscar May for the Associated German Fire Offices are commendably brief and free from rigidity. Considering, however, that the author has found it desirable to publish the above explanatory volume of over one hundred pages, and that in his fear lest he should unnecessarily hamper wiring firms, he has omitted any and every rule relating to insulation, it will, perhaps, be thought that both brevity and flexibility have been carried a trifle too far. Rules sufficiently precise to prevent all jerry work, and at the same time in no way hindering good work, being in Dr. May's opinion impossible, he prefers to make none at all, and to leave everything to the competency, honesty, and conscientiousness of the inspecting officer. This may be all very well so far as the householder and fire-office are concerned, but it is rather hard on the wiring contractor, who must perforce carry out the job with an eye rather to synchronising with the inspector's fads than to intrinsically good work; a rule specifying a certain percentage leakage of current would seem to meet the difficulty better than any other. The rules, two and twenty in number, are based upon those of the Phœnix Fire Office, and appear, with the exception of the omission referred to above, to be of the ordinary character. Instead, however, of simply limiting the current density by specifying a maximum permissible fall of potential, a sort of sliding scale is laid down beginning with a current density of 3,225 per sq. inch for conductors up to $\frac{7}{1000}$ths of a sq. inch cross-section, and ending with a current density of 1,290 for all conductors over $\frac{7}{100}$ths of a sq. inch cross-section. The smallest conductor allowed is about No. 20 S.W.G. The volume of explanations should be of considerable use in making clear the exact intention of the rules.

HERTZ'S EXPERIMENTS ON CATHODE RAYS.

BY DR. OLIVER LODGE, F.R.S.

The translation of Dr. Lenard's most interesting Paper developing one of Hertz's minor discoveries, that the molecular bombardment from the negative terminal in vacuum tubes can penetrate thin metal films, suggests the propriety of also publishing a translation of Hertz's original brief Paper.

It will be observed that with his customary caution Hertz only asserts transparency for films that are thin enough to be transparent to light, whereas Lenard finds the transparency of metals for "cathode rays" immensely greater than their transparency for light. He also finds that everything is transparent if thin enough, and not only metallic films as Hertz at first thought. Lenard's success in getting the rays out of vacuum into ordinary air, through a plate thick enough to stop every trace of light, makes experiments on the phenomenon very much easier.

I agree with Prof. Fitzgerald in thinking it extremely improbable that in these rays we have any directly ethereal manifestation. Everything points to action of residual matter.

ON THE PASSAGE OF CATHODE RAYS THROUGH THIN METALLIC FILMS.*

BY H. HERTZ.

Cathode rays differ from light chiefly with regard to capacity of penetrating solid bodies. Even such bodies as are the most transparent for light of all kinds, offer an impenetrable obstacle to the passage of cathode rays even in the thinnest procurable films. It is all the more remarkable that the metals, opaque as they are to light, should transmit cathode rays, if only to a very small extent. Thicker metallic films are, indeed, opaque to cathode rays as well as to light, but metallic films thin enough to allow of the passage of a portion of the incident light, also allow a portion of the cathode rays to penetrate; in fact, the percentage of cathode rays transmitted appears to be somewhat larger than the percentage of light. This may be shown by the simplest experiments. A plane phosphorescent glass plate, preferably a piece of uranium glass, is partly covered on one side, which we will call the face, with real gold leaf; a few fragments of mica are fastened on to the gold, and the face is exposed to cathode rays proceeding, say, from a plane circular aluminium cathode 1 cm. in diameter, say, at a distance of 20 cm. from the cathode. As long as exhaustion has not proceeded very far, and the cathode rays fill the whole discharge tube in the form of a dense blue light cone, the glass only phosphoresces outside the area covered with gold. Phosphorescence is at this stage chiefly due to the light of the discharge, of which light the gold leaf only transmits a very small portion. But as exhaustion proceeds and the interior of the discharge tube becomes darker, the cathode rays proper begin to strike the covered glass, and the latter commences to phosphoresce also behind the gold film; this luminosity increases, and when the cathode rays have attained their maximum development, the gold leaf, as seen from behind, only appears as a faint veil on the glass plate, chiefly distinguishable at the rims, and by the minute folds in it; so we can hardly say that it casts a shadow. But the thin mica plates placed upon the gold film cast their intense black shadows through it upon the glass. The cathode rays, therefore, penetrate the gold leaf, apparently with little loss. The same experiment I performed with equal success upon real silver leaf with aluminium foil, with various kinds of imitation silver and gold leaf (tin, zinc, and copper alloys), also with chemically precipitated silver films, and with layers of silver, platinum, and copper deposited in a vacuum by the discharge. These last films were much thinner than the beaten metal foils. I found no characteristic differences between the different metals. The best material for the experiments appeared to be the beaten aluminium as obtained commercially. It is almost completely opaque to light, transmits the cathode rays well, is easily manipulated, and is not attacked by the cathode rays, while a sheet of silver foil, for instance, is quickly disintegrated by them in a peculiar manner.

The assumption that in these experiments the cathode rays have penetrated the substance of the metal might meet with the objection that metal sheets of such thinness are full of small holes, and the cathode rays might have penetrated these instead of the metal. In the case of the beaten metals, in which the phenomenon is most striking, the presence of a multitude of pores cannot be denied; but the total area of the openings would surely not exceed a small fraction of the surface of the metal, and is insufficient to account for the bright luminosity of the covered glass. Besides,

* *Wied Annalen*, 45, p. 28, 1892.

Digitized by Google

the covered portion of the glass appears perfectly dark when we look at the face of the glass as seen from the cathode. The cathode rays must, therefore, have arrived at the glass along a path which cannot be retraced by the light they produce ; they cannot, therefore, have entered through the openings in the metal film attached to the glass. Further, if we superimpose one metallic film upon the other, the number of coincident openings will be infinitesimal ; but the cathode rays produce strong phosphorescence in the glass even under a double layer of metallic films ; we may, in fact, perceive the phosphorescence of the glass and the shadows of objects in front of it under a three or fourfold layer of gold leaf or aluminium foil. It is curious that a double layer weakens the luminosity much more than might have been expected after the slight weakening due to a single layer. I believe that the following consideration affords a sufficient explanation. The metal covering represents a reflecting surface from which the light of phosphorescence is reflected. Since this surface prevents the light from radiating in the direction of the cathode, it doubles its intensity for the surface away from the cathode. If we now suppose that the metallic film only allows one-third of the cathode rays to penetrate, yet the luminosity is not reduced to one-third, but to two-thirds of the original value ; the second layer, however, will reduce it to two-ninths, and further layers will rapidly extinguish the phosphorescence. If this assumption is correct, metal plates transmitting more than half the cathode rays should not diminish the luminosity at all, but the glass should phosphoresce behind such films even more strongly than at the uncovered portions. I think I have found this surmise justified in chemically precipitated silver films of suitable thickness ; but the observation is somewhat doubtful since the greyish-blue light of the gas is seen through the uncovered portions of the phosphorescent glass, and the luminosity of this light cannot with perfect certainty be distinguished from the green phosphorescence.

Finally, if the cathode rays passed through the openings of the metal, they should proceed on their rectilinear paths after this passage. But they do not ; the rays are, in fact, diffused by the passage in about the same manner as light is diffused by passing through a turbid medium such as ground glass. We divide off the whole section of the cylindrical discharge tube by a metal plate, place in this a circular opening some millimetres in diameter, and close this by a piece of aluminium foil. If we now hold a phosphorescent glass plate just behind the opening, we obtain, as might have been expected, a clear and bright image of the opening on the glass. But if we remove the glass plate by one or two millimetres the image appears considerably enlarged and its brightness correspondingly diminished, its rim at the same time appearing foggy. On increasing the distance to several millimetres the image of the opening appears exceedingly foggy, enlarged, and feeble, and on further removing the plate the discharge tube behind the diaphragm simply appears dark. That this is solely due to the faintness of the cathode rays dispersed by the small aperture is at once evident when we make several such holes closed by aluminium foil in the diaphragm. The simplest diaphragm for this experiment is a wire grating just beaten, and covered with a piece of aluminium foil. Behind such diaphragms the whole discharge tube glows with an evenly-distributed, moderately-bright light. The phosphorescence is strong enough to allow of the separation of pencils of rays out of the diffuse cathode rays by means of further diaphragms, and enables us to prove that even after their passage through the metal foil the cathode rays have not lost their properties of rectilinear propagation, of deflection by the magnet, &c.

The phenomenon of diffusion of the cathode rays during their passage through thin bright metal films may be connected with the other fact established by E. Goldstein,* that the portion of the cathode rays reflected by the front surface of such layers is diffused.

COST OF ELECTRICAL ENERGY.†

BY R. E. CROMPTON, M.INST.C.E., VICE-PRESIDENT.

I address this Paper to all who are interested in electrical supply, but especially to the engineers who design and who work electrical supply plant. It is almost exactly six years since I read a Paper before this Institution‡ on this subject, and three years since I read a similar Paper before the Institution of Civil Engineers.§

I should be glad if those who are really interested in the subject would find time to glance over these two Papers after reading the present one, as there is much contained in them which might have been repeated here with advantage if I had not feared to unduly lengthen the Paper.

* E. Goldstein, "On the Reflection of Electric Rays," *Wied. Ann.* 15, p. 246, 1882.

† Paper read before the Institution of Electrical Engineers, April 26th.

‡ *Journal*, Institute of Electrical Engineers, Vol. XVII., p. 349.

§ *Proceedings*, Institute of Civil Engineers, Vol. CVI., p. 2

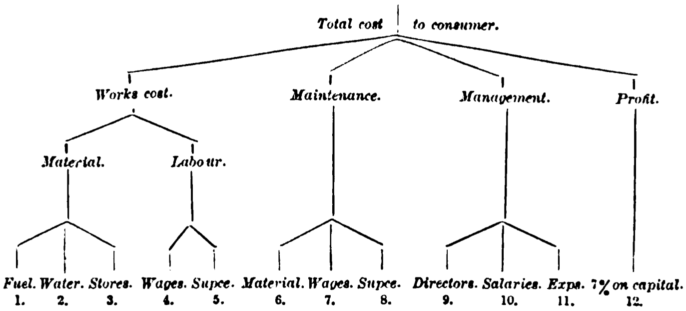
For convenience and brevity I use the word "works" for the whole plant of an electric supply company ; such works may have several generating stations. I use throughout the word "energy" for the electrical energy, and I speak of the two well-known systems of distribution as "direct" or "converted" systems. By direct systems I mean all two, three, or other multiple wire systems, with or without storage, in which the energy is supplied direct from the dynamos to the mains, and from the mains to the users, without change of pressure. I include amongst converted systems all those in which the energy is either generated at a high pressure, or converted up to a high pressure for transmission through the mains, and afterwards converted to the lower pressure at which it is supplied to the users.

In this Paper I do not deal with works using water power, but solely with those in which the electrical energy is obtained from fuel.

The total cost to the user may be grouped under four heads—Works Cost ; Maintenance ; Management ; Profit.

These may be conveniently sub-divided into 12 sub-heads or divisions, as follows :—

TABLE I.



Of these 12 heads I propose to deal at length with 1 to 8 only. The remaining heads of management and profit are outside the province of us enigneers, except in one important particular, which is that the interest or profit to be paid on the capital employed is affected by the choice of system used, and by the skill of the designer of the works, so that it is necessary for us to deal with it.

Let us assume that our ideal works are designed for the most economical production of 5,000,000 units of energy per annum, distributed to users in a large town and under average conditions. We are now in a position to estimate with considerable accuracy that the capital required for the preliminary expenses, for obtaining the requisite Parliamentary powers, and for the complete equipment of such works will not exceed £500,000, or at the rate of 2s. per unit sold per annum. I have arrived at this figure after considerable study of the capital account of existing companies, and of works carried out by local authorities, and I find that it is nearly certain that several existing works will reach this figure as soon as their plant is completed to the scale intended, and worked to the full output ; so that, if we consider that entirely new works could now be certainly carried out at a lower cost than that of any existing works, it will be seen that my estimate is on the safe side.

Now I think that such works ought to be able to include in the total cost to the consumer such a sum as profit as will yield 7 per cent. per annum on the whole of the loan as well as subscribed capital. In the case of a local authority, a portion of this 7 per cent. would be applied to paying the interest and sinking fund on the original loan, and the remainder would be applied as a profit in the reduction of local burdens or in introducing local improvements ; but in the case of a joint-stock company this capital of £500,000 might advantageously consist of £200,000 in ordinary shares, £100,000 in 6 per cent. preference stock, and £200,000 in 4 per cent. debenture stock, so that the average of 7 per cent. on the whole £500,000 might be divided up as follows :—

4 per cent. on debenture stock	£8,000
6 per cent. on preference stock	6,000
10½ per cent. on ordinary stock...	21,000
Total	£35,000

This sum of £35,000 is equal to a profit of 1·68d. per unit sold. The cost of managing such a company can also be dismissed in a few words. Under this heading it is convenient to group directors' fees, salaries of managing staff and office, meter readers, collectors, all stationery, law and audit charges, rates, taxes, and insurance. If we take the practice of the best managed works as a guide, we find that about £8,200 per annum is sufficient to cover all these charges for the largest output that has been yet obtained. It is evident that a sum of £9,000 a year would be an ample one for the management charge on the output of 5,000,000 units. This management charge, therefore, works out at 0·42 a unit.

You will see, then, that at the scale of working that we are now considering, which is at a scale of output certain to be reached

Digitized by Google

within a year or two by a large number of works, the management and profit items, taken together, should amount to 2·1d. per unit. As I have said above, we engineers have nothing to say in controlling these figures. They are certain to be reached in course of a few years, as it is a mere question of output. The question which I now propose for your consideration is this: What chance have we of reducing the present works cost and maintenance cost included in the sub-heads 1 to 8 to such an extent that the energy may be sold to the public at, possibly, the low figure of 3d. per unit? I believe that Mr. Swinburne has stated that electrical energy, whenever the demand is continuous, such as for certain electrolytic or electro-metallurgical processes, can be generated and distributed to short distances at a works and maintenance cost of ¼d. a unit. I believe Mr. Swinburne has good grounds for this estimate, if cheap fuel is available. But for our present purpose, which chiefly concerns the supply of electrical energy used largely for electric lighting, and to a minor degree for power, we cannot fix such a low figure for our ideal works and maintenance cost for the future. Mr. Swinburne's case and those which we are now considering differ so widely. We can hardly hope for many years to come to improve the load-factors of works for general supply much above 20. The average of the London stations is still a long way off this figure, and I fear that the extensions of the use of energy for power and purposes other than lighting are likely to go on for some years to come at a slow rate. At a load-factor of 20 you must remember that all maintenance charges work out nearly five times as great as they would be if the output was continuous. It is useless to put before you ideal figures which we cannot hope to approach. I propose, instead, to adopt figures which we may hope to reach at no distant period, and have therefore prepared those given on Table II., and I give reasons for fixing on them as I deal with each sub-head in turn.

FUEL AND WATER.—DIVS. 1 & 2.—FUEL.

I agree with Professor Kennedy in the remarks that he made on my Paper read before the Institution of Civil Engineers* that the importance of the cost of the fuel used on electrical energy supply works is not to be measured merely by the money spent on the fuel itself, but that it is, to a certain extent, a measure of the quantity of plant that must be employed, and so affects the cost of upkeep of the plant, and to some extent every cost item, except, perhaps, management and profit items.

At a very early stage in the history of electrical supply works it was found that in practice the amount and cost of the fuel used differed very widely from the amount estimated from the known efficiency of the plant.

In 1883 modern engine builders were making engines and boilers using less than 2½lb. of good coal per indicated horse-power, and the mechanical efficiency of these engines was certainly not less than 85 per cent. At that time dynamos could be made of 85 per cent. efficiency. We all thought that our distribution losses should not exceed 15 per cent.; so that, putting these figures together we were justified in hoping that our fuel bill would not exceed 5½lb. of coal per unit sold. We soon, however, found that in practice we could not approach such a degree of economy; so that the opinions of practical engineers in charge of supply works rapidly veered round to the opposite extreme, and among these gentlemen, even in 1888, when I estimated that the figure which was then prevalent of about 24lb. of good Welsh coal used per unit sold might in the future be reduced to 5¾lb., I met with much incredulity. At so late a date as that of my Paper before the Institution of Civil Engineers in 1891,* Mr. Raworth, in the course of discussion, stated that to his knowledge from 19 to 22lb. of coal was commonly being used, and that he considered the figures I then gave—namely, 7·9lb. for the Kensington and 6·5lb. for St. James's stations, for the best months of the year—were so satisfactory that they opened up a prospect of a new era for shareholders in those companies. I am glad to say that since that date improvement has been very regular; during the past year we have several times seen recorded during the winter months—in which, of course, the economy of fuel is at its best—a fuel consumption under 5lb. of Welsh coal per unit sold; so that my forecast, made six years ago, has already been more than justified.

I have arrived at my new possible or ideal figure of 2½lb. of Welsh coal per unit sold in the following manner:—I find that we can in London count on obtaining this coal having an average calorific value of 14,500 B.T.U. per lb. With proper arrangements for heating the feed water to nearly boiling point boilers can be obtained which will evaporate 12lb. of water at our working pressure of 150lb. I think that the losses due to irregular working and banking fires can be so minimised that 2½lbs. may evaporate 25lb. of water into dry steam—not on tests only, but as shown on the monthly bills. Condensing steam-engines can and will be made for us using not more than 12lb. of steam, at from three-quarters to full load, or 13lb. of steam at from half to three-quarters load per indicated horse-power hour. To these engines dynamos can be coupled direct of such efficiency that the combination will not use more than 18½lb. to 20½lb. of steam per unit per hour, measured at the dynamo terminals at the corresponding loads, so that an average of 20lb. per unit generated may be counted on during the time that these engines are actually at work. This allows for 10 per cent. of the steam evaporated being condensed in the pipes, or used in feed pumps or other obscure sources of loss, and a further 10 per cent. for our distribution loss, in order to account for the 25lb. of water I require to be evaporated by the boilers.

It appears to me that the most convenient method of discussing the problem of reaching these ideal figures is to consider in turn the fuel that we use and the boilers and other steam-producing apparatus, the engines for using the steam, the dynamos for generating the energy, and, finally, the means for distributing the energy to the users—in each case with a view of locating the losses that now take place, and considering the best means of minimising these losses as far as may be possible.

In London the favourite fuel hitherto used in electric supply works has been Welsh coal of the best quality, as it has been found that the cost of the carriage of fuel form such a large part of its total cost when delivered on to the works, that in most cases it pays best to use nothing but fuel of the highest calorific value. This value in the case of the best Welsh coals may be taken at 14,500 British thermal units; for, although values as high as 16,700 have been noted in the case of Nixon's and a few other Welsh coals, yet is probable that these exceptional values are not attained on the average, even from coals from the very same seam.

As our ideal figure of 2½lb., therefore, contains 36,250 B.T.U., it will be convenient, for purposes of comparison, or for considering the use of other fuels, to point out that 2½lb. of Welsh coal is equal to 36¼ B.T.U. per watt-hour of the energy sold.

Table V. gives the calorific values of various fuels, determined by Bryan Donkin and Co. (Limited), arranged in the order of their efficiency when used in a Lancashire boiler fitted with Perret's furnace.

TABLE V.—*Calorific Values of various Fuels, determined by Messrs. B. Donkin and Co. (Limited).*

I have been enabled, through the kindness of Messrs. Bryan Donkin and Co., to avail myself of these figures, which show at a

* *Proceedings* Institute of Civil Engineers, Vol. CVI., p. 2.

Digitized by Google

glance the (comparative) value of Welsh coal as compared with other steam coals, of large Welsh as compared with small Welsh, of small anthracite, large and small coke, and coke dust; and, for the information of those who hope for great things from the use of town refuse for steam-raising purposes, I give at the foot of this table Mr. Bryan Donkin's determination ot its value. The Perret furnaces used for these determinations is well suited for making such a comparison, as it burns efficiently all classes of fuel, even the smaller and finely divided coals, coal dust, coke breeze, and coke dust, and in these cases minimises the loss of small combustible, which is liable to fall through the grate bars. The results shown on this Table emphasise the fact that in practice we can utilise a large percentage of the thermal unit in such fuels as anthracite, Welsh coal, and coke, the heating power of which lies chiefly in the solid carbon which they contain; and that the small and dust fuels of the same class are only less valuable because a part of them is liable to fall through the bars, and because, being so finely divided, they usually contain more earthy matter to form clinker and ash in the furnace than the larger coals or cokes, which can be more easily hand-picked, sorted, or washed free from such impurities.

The very large class of steam coals used in the Midlands and North is only represented in the Table by the one test of the Yorkshire Ravensworth coal, but the majority of these coals, whether station, which my firm put down for the London, Chatham, and Dover Railway at Victoria Station in 1883. These boilers had copper fire-boxes, and, on test trials, gave an evaporative efficiency of 8½lb. to 9lb. of water per lb. of Welsh coal. This type is in most respects satisfactory; but, on account of the level of the grate bars being so much below the level of the fire doors, it is difficult to propely clinker the fires—so much so that when a batch of coal is used that contains much clinker it is very difficult to clean the fires in a reasonable time, so that the evaporative efficiency is thereby much reduced. From this cause the average efficiency of locomotive boilers does not much exceed 7lb. of water per lb. of coal when taken from the monthly bills, and under the conditions usually met with in supply works. It is also not an easy matter to bank the fires of a locomotive boiler in an economical manner.

The St. James and Pall Mall Company have used large boilers of this type made by Davey, Paxman and Co.; and the Metropolitan Company have used others made by Hornsbys—all, I believe, with good results. I, however, have been unable to obtain the correct evaporative duty. This type of boiler is rather more costly to maintain than the other types; the fire-door ring is liable to give trouble from leakage, and a great deal of space must be wasted in order to give access to the smoke-box end of the boilers for tube-sweeping purposes.

large engine coal, nuts, or engine slack, only contain from 50 to 70 per cent. of carbon in the solid form; so that, although on account of the thermal unit contained in the combined carbon and in the hydrogen, these fuels, when tested in the calorimeter, may give a calorific efficiency approaching that of the anthracite and Welsh coals, yet we find very rarely that any form of furnace now in use is able to utilise any considerable percentage of these hydrogen units, even when the best of the modern automatic stoking apparatus is used. So that. when judging the comparative value of these fuels, we should always remember that it is far more difficult to obtain a high boiler efficiency from these latter fuels than from those which contain the larger percentage of carbon in the form of coke. In order that you may conveniently calculate the T.U. contained in a pennyworth of coal of various qualities and prices, I have prepared Table V. (*a*), which shows this at a glance for all fuels from 10,000 up to 16,000 B.T.U. per lb., and for all prices from 5s. up to 22s. per ton.

Fuel and Water.—Divs. 1 and 2.—Boilers, Economisers, &c.

The boilers which have hitherto been chiefly used in electric supply works have been of the locomotive, marine, or semi-marine tubulous, or Babcock and Wilcox type, and the Lancashire type.

Locomotive Type.—Several large locomotive boilers were put in by Mr. W. H. Maw for driving the *Daily Telegraph* printing works, and the success of these was so great that I asked him to design for me boilers of the same type for the first London central

The Marine and Semi-Marine Type.—The marine type has been used in a few instances, notably in the Whitehall Court station of the Metropolitan Company, and is highly economical; but it is a rather costly boiler to construct. Equally good results may be obtained from the semi-marine type, which is a modification of it, made by Messrs. Davey, Paxman and others, which they call the "Economic" boiler; in this boiler the flues are carried right through from front to back, and the products of combustion are deflected back through the tubes by a firebrick back. In Scotland this boiler is called a "dry-back" boiler. It has many merits: it is very simple, and easily repaired; the intensely heated "dry-back" acts as a very good smoke preventer, so that Midland steam coals can be used without producing smoke, which is not the case with either the locomotive or Babcock's type. Prof. Kennedy has used a large number of these boilers for the Westminster Supply Company, and, he tells me, with uniformly good results from every point of view. The test of this boiler given in Table IV. shows it to be of the highest efficiency. I have not personally had much experience in its use until quite recently at the new central station in Shoreditch for the Great Eastern Railway. The sole fault in this boiler (and it is not a great one) is the rather awkward position of the smoke-box over the fire door.

Babcock and Wilcox Boilers.—These boilers, as you well know, consist of a large group of inclined tubes, having the water inside the tubes, the highest end of the tubes being at the firing end of

Digitized by Google

the boiler. The tubes are connected at both ends by special headers to steam drums placed overhead. The firing is carried on on large grates, and the products of combustion are deflected by fire-tile bridges so that they are obliged to follow a serpentine course through the tubes, the hot gases passing several times transversely to the tubes. My experience in the use of Babcock boilers has been altogether satisfactory, and I believe that the best evaporative efficiency yet obtained in supply works has been with these boilers. I make this statement all the more readily as in my 1891 Paper* I said that this class of boiler, presenting as it does such considerable radiating surface of brickwork, would not give such economical results during the long hours of standing with banked fires as other boilers which are internally fired; but since that date the skill of the designers, and the great skill and attention of the users, has resulted in so minimising these losses that I believe these boilers stand quite at the head of the list, not only as regards economical working on full-load tests, but also in the small use of fuel when standing banked. These are my own observations, but I understand that the experience of others has been equally satisfactory, at least wherever Welsh, anthracite, coke, or other smokeless fuels are used. I am told that when used with smoke-producing fuel there is a tendency for the lower row of tubes to cool down the products of combustion, that these tubes become coated with soot, and the evaporative result is unsatisfactory. I believe, however, that the makers have now introduced special means to get over this difficulty. The chief refinements that those who use these boilers have been able to introduce, and which have led to reduction in the waste of fuel during long hours of light firing and banking, are principally in the alteration of ash-pit, flue doors, and dampers, so as to regulate the air admission with great nicety, or to completely shut it off. We also find that the maintenance of the fire-tile bridges between the tubes which cause the gases to follow the undulating path above described is a matter of extreme importance; and last, but not least, this boiler should be kept perfectly clean. Up to a few years ago we were content with periodical cleanings and scalings; but now, by the use of suitable boiler fluids and frequent blowing off at the surface as well as at the lower cocks, we find that we can keep the interior of these boilers as free from scale, and in all respects as clean, as when they left the makers' hands. Test results with these boilers have shown that 9¾lb. of water can be evaporated with Welsh coal at 170lb. boiler pressure: if the calorific value of this coal is taken at 15,000, this is equal to 76½ per cent. efficiency; and, as my table of costs will show you, in practice we have reached to within a narrow percentage of this figure, even when all banking coal and other sources of waste are taken into consideration.

Lancashire Boilers.—We are told from time to time that the evaporative efficiency of this boiler ought to be the highest, and its maintenance cost the lowest, of any boiler. I believe the latter claim to be better founded than the former. The boiler is easy to clean, and the repairs should be few at low pressures and far between; but it must be remembered that we have no extended experience of the cost of maintenance of these boilers when used at the higher pressures of 140 to 170lb. per square inch, now so common in electric works—as, for instance, the maintenance of the usual fusible plug is not an easy matter, and it is, therefore, necessary to depend on some form of low-water alarm, which is always a troublesome piece of apparatus; again, although the accidental lowering of the water level of a locomotive or a Babcock boiler, or an "Economic" boiler may have serious consequences, yet these are nothing to what occurs when the flues of a Lancashire boiler come down from this cause.

As regards the evaporative efficiency of the Lancashire boiler, I think it has been somewhat overrated. Owing to the fact that the great majority of Lancashire boilers are in use in the Midland and Northern counties, where the fuel used is cheaper than that we use in London, and where little or nothing is said if smoke is produced, and where low cost of maintenance is of higher importance than high evaporative efficiency, mill engineers have been led to regard this as the one and only boiler; but that this type is not efficient when taken by itself is amply proved by the fact that no first-class mill is ever fitted up without the addition of economisers—in fact, we may say that the Lancashire boiler without its economiser is only half a boiler. In most cases the gases would leave the Lancashire boiler at 700deg., leaving 300deg. to be taken out of the gases by the economiser; whereas in tests of the locomotive, marine, semi-marine, or Babcock boilers the gases leave the boiler itself at a temperature very slightly in excess of that of the steam; so that in this latter case an economiser would be a refinement and not a necessity. I do not think this fact has been sufficiently brought home to us engineers when the merits of the Lancashire type of boiler have been so persistently put before us by outside engineers, so that many of us—myself included—have made the mistake of putting down Lancashire boilers for supply stations in country towns without economisers, thinking that if we made these boilers large for their work we should get the required economy, whereas with this type the only way to get high economy is to use a rather small boiler and a large economiser. At any rate, the electric works using Lancashire boilers have hitherto not shown at all well in comparison with other types. In towns where the fuel is obtained so near to the works that the cost of carriage is small compared with the actual cost of the fuel itself, it pays to put down boilers fitted with special stoking plant to deal with these inferior fuels. In most of these cases Lancashire boilers have been used, but, as I shall show hereafter, the results hitherto obtained from the use of such cheap fuel have not been very satisfactory; in fact, the very cheapness of the fuel itself has been a snare to the works engineers, causing them to neglect refinements in fuel economy to such an extent that in many cases the greater part of the saving which they ought to have shown from the low price of their fuel has been lost. In some cases the price of their fuel has been actually higher that in the best London works, where economical working has been studied.

It is now time to put before you in a tabular form the data which I have been able to prepare to show the working efficiency of the boiler plant used in 10 of the works which I propose to compare. In all cases the quantity and calorific value of the fuel used is given with sufficient accuracy; but I have not in all cases been able to ascertain the water used per unit with the same accuracy, although this would have been a very desirable check on my other figures.

Table III. shows the actual boiler efficiency observed in these 10 works; I have designated them by letters, which enable you to identify them, in the following tables:—

TABLE III.—*Boiler Efficiency.*

Works.	System.	Type of boiler.	Fuel.		Lbs. of fuel per unit sold.		Lbs. of water evaporated per lb. of fuel.	Efficiency of boiler per cent.

In all the tables they are arranged in the actual order of fuel economy, F showing the largest consumption of fuel per unit sold, and W the smallest.

Table IV. gives the evaporative duty and efficiency of several types of boiler determined at special tests.

I would draw attention to the remarkably high results obtained by Prof. Kennedy, shown on Table IV., in his Glasgow trials, and beg that this result, which was obtained with marine-type boilers using small gas works coke, may be compared with that shown by Bryan Donkin, in Table V., with a Lancashire boiler using similar coke.

Referring to Table III., works J are using Lancashire boilers fitted with automatic stokers of the Vicars type. In this case, which is under my own control, every means has been studied to increase the evaporative efficiency of the boilers; but this is a typical case of the difficulties attending the use of small coal, even if it be of a fairly high calorific value. In this case a considerable part of the loss is due to the small coal falling through the bars. The coal supplied is of variable caking quality: sometimes it cakes together sufficiently to reduce this loss; in other cases it hardly cakes at all, and from 15 to 20 per cent. of the combustible is lost. The point I have above referred to of the extreme difficulty of utilising the heat units in the hydrogen is here met with. If the air admission is not managed with the utmost nicety, the losses due to over-dilution of the products of combustion by air become so great that the evaporation is largely diminished, and this without any apparent neglect on the part of the stoker.

Before leaving the subject of boilers, I ought to say a few words on the use of forced draught. A good many of us have formed the opinion that one of the best methods of meeting the short period of heavy load is by the use of forced draught applied to a closed ash-pit, as has been done by Meldrum and others. It is evident that existing boiler plant might in case of emergency, or for short periods, be forced to evaporate 50 per cent. more steam than at present; and this would be particularly convenient to meet the times of maximum load, so that in this way the waste of fuel due to lighting up extra boilers for these short periods might be reduced or altogether avoided. We should also be able to burn small or finely-divided, and hence cheaper, fuel during the times of light load in an efficient manner. Another method of reducing the cost due to the necessity of lighting up additional boilers for the period of maximum load would be by using liquid fuel, to be used only on emergency, or during these periods of maximum load.

As is well known, Mr. Holden, on the Great Eastern Railway, has been very successful in the use of astatki, or crude petroleum, with his works boilers, and on some of the locomotives of the Great Eastern Railway. The principal objection to his system appears to be the noise of the blower, and the same applies to nearly all the systems of forced draught where an injector blower is used; but there seems little doubt that this noise may be minimised by properly arranging the air inlet—that is to say, by drawing the air fom a point outside the building, placed so that the noise at the entrance cannot be a nuisance to the neighbours. As it is evident that it is very easy and convenient to safely store such liquid fuel in deep underground tanks, and as is evident, in face of the troubles we have lately gone through from the coal strike, that it is necessary to have such a considerable storage, this question of the employment of liquid fuel deserves careful attention by all interested in supply works.

There is another point to which I wish to call attention. A long and interesting series of articles has recently appeared on water-tube boilers in the *Engineer*, in the course of which the writer more than once states that it is impossible to force any of the existing types of water-tube boilers, as any such forcing invariably results in the production of wet steam, and consequent loss of economy. It is difficult to know how the writer could have formed such an erroneous impression. My own experience is that the works where the best results have been obtained are those where the Babcock and Wilcox boilers have been forced the hardest. At works W, the boilers, which are nominally supposed to evaporate 11,000lb. of water per hour, have frequently been forced to 16,000, or about 50 per cent. in excess of the duty guaranteed by the makers, and at such times of heavy forcing there has never been any trace of priming or wet steam.

On the whole, I think that there is a fair prospect of improving and supplementing our boiler plant and our methods of working it so that we may obtain in the future an average boiler efficiency of 70 per cent.—equivalent to an evaporation of 10lb. of water at a pressure of 150lb. when using Welsh coal, and an equivalent smaller evaporation from inferior and lower-priced coal.

(To be continued.)

Electric Tramways in Russia.—The municipal council of Nijni-Novgorod has just decided upon the construction of three electric tramways.

THE GLASGOW CORPORATION ELECTRIC SUPPLY.*

BY WILLIAM ARNOT.

The Provisional Order was obtained on August 14, 1890. Lord Kelvin was consulted in October, 1891, and advised supply with a direct current at not more than 200 volts. In November, 1891, Prof. A. B. W. Kennedy was requested to prepare a scheme. A site was obtained in Waterloo-street, at the corner of Mains-street. On Saturday, February 25, 1893, the arc lamps on the principal streets were first lighted, and the current was switched on to the incandescent mains on Saturday, April 22, 1893. The site at Waterloo-street station measures about 31 yards by 31, and contains 972 square yards. The building stands on a layer of concrete 2ft. thick laid throughout the entire block. It consists of the engine room, first floor with offices and workshop, and second floor with laboratory, drawing office, meter room, and cable floor. Behind the main building is the boiler house, with the battery room above it.

Boilers.—These consist of six marine type steel boilers, measuring 12ft. long and 10ft. in diameter, working at a pressure of 160lb. They have each two furnaces of the corrugated type, with an internal diameter of 3ft. The fire grates are 5ft. long. There are 194 wrought-iron lap welded tubes in each, 2¾in. external diameter and 8ft. 6in. long. A smoke box is on the front of each boiler connecting the tubes to an uptake which communicates with the main flue. This is led into the chimney at a height of 15ft. There are no underground flues. Each boiler is covered with 2½-in. composition, and stands on two cast-iron brackets. There are two "Tangye" (steam 7in., water 4½in.) pumps, each capable of delivering 4,800 gallons per hour, either through a Wright's feed-heater or direct. There is an injector connected to the cold feed capable of delivering 5,000 gallons per hour. The water tank has a capacity of 3,500 gallons.

The steam pipes are 7in. and 8in. diameter, steel, lap welded, with wrought-iron flanges screwed and brazed. In the engine room the steam main forms a complete ring, slung by means of rods from cast-iron brackets. Four of the boilers have a duplicate connection to this ring, the remaining two have one connection.

Engines.—These are Willans' central valve compound engines.

Dynamos.—The nine dynamos are two-pole shunt-wound with drum armatures. They are coupled direct to the engines, with a heavy disc to ensure steadiness in the running. The combined plant stands on one sole plate. The total maximum output of the several dynamos is 1,190 units.

The absolute necessity of working without making any smoke has led to the use of gas coke, obtained from the Corporation Gas Works. At a preliminary trial on one boiler, in April, 1893, when working with a very light load, the water evaporated was 27,458lb. in eight hours, 3,770lbs. of coke being used.

Mean boiler pressure, 149lb.
Mean feed temperature, 145°.
Evaporation per hour, 3,432lb.
Actual evaporation per lb. of coke, 7·28.
Reduced to standard ....8·15.

The value of this per unit generated was ·24.

The analysis of the coke showed :—

Moisture	10·68
Ash	10·16
Loss on ignition	79·16

Assuming this to be carbon, it gives 11,416 thermal units per lb. The result of measurement in a calorimeter gave 11,286. It may therefore be taken that the evaporative value of this coke is 11·75 pounds of water under standard conditions.

These figures do not take account of the coke used at night when no work is being done. The trial only lasted for eight hours. An extended test was made by Prof. Kennedy on the 2nd and 3rd of November, when the following results were obtained :—

Total duration of experiments	hours	48
„ Coke put on fires	lbs.	61,900
„ Coke used in boilers of which the stop valves were closed	„	9,260
„ Net coke used for steam	„	52,640
„ Water through meter, allowing for all differences of level	„	378,970
„ Water used while station was shut down	„	16,296
„ Net water used during running hours	„	361,674
„ Electrical work at dynamo terminals	E.H.P. hours	8,991
Electrical work in Board of Trade units, or kilowatt hours		6,708
Pounds of water evaporated per lb. of coke put in fire, actual,		6·12
„ „ „ „ „ „ reduced to standard,		7·38
„ „ „ „ of net coke, actual,		6·87
„ „ „ „ „ reduced to stand.		7·91
Ratio of stand-by fuel to total fuel on fires		14·96 per cent.

* Abstract of a Paper read before the Institution of Engineers and Shipbuilders in Scotland, March 20th.

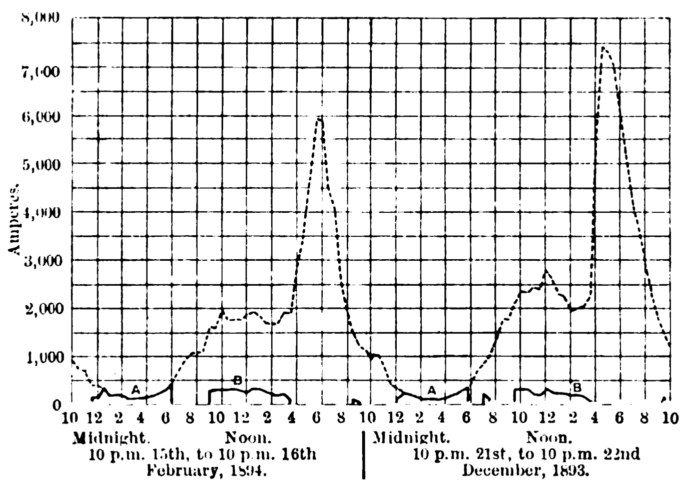
Maximum load	"	669·4
Ratio of mean to maximum load	29·7	per cent.
Load factor per actual hours and engines	68·4	"
Mean steam pressure, lbs. per sq. inch above atmosphere		151·5

The total coke put on the fires was 61,900, but of this 9,260 was required to supply damped fires and condensation in the steam pipes through the night. The main steam pipe is always under steam for the sake of the joints. The ratio of 14·96 per cent. between these figures is rather high ; the water consumption is much too high. These figures will be improved, faulty traps and drain cocks being responsible for much of the loss.

The engines and dynamos combined show an excellent efficiency. Curves given by the author show that with an engine load factor throughout the station of 50 per cent., or half load, an efficiency of 80 per cent. can be maintained in the generating plant.

Accumulators.—A set of accumulators is placed over the boiler house. This position keeps them in a suitable temperature ; otherwise during the winter they would be affected by frost. The set consists of 114 cells. Each cell has 61 lead plates, with a capacity of 1,000 ampere hours, with a discharge rate of 200. There are six cells as



Load Curves.—Full line curves A. A., Battery Discharge ; B. B., Battery Charge.

repair cells, or, as they are sometimes called "milkers." From these plates are taken to replace faulty ones in the working set, and should a cell show any weakness it is not allowed to discharge for a day, but is short-circuited by two "milkers" in series. It has thus four volts across it.

Distribution.—The distribution begins practically at the switchboard. The current is generated at from 210 to 230 volts, and is kept constant at the feeding points at 205, or 102 on each side of the system. The balance is maintained in the station by means of two 100-volt machines. The difference in current between the two sides does not generally exceed 200 amperes at any load. Exceptional nights have been known, such as 650 amperes, when both machines had to be run on the one side.

I have put before you (see Figure) curves showing one of the heaviest days, and one of last month, which shows a falling-off. I have noted the ratio between the amperes of current applied for and the maximum output. In December it was 54·3, and in February 37·1. The real efficiency of running is shown in the plant load factor, which in February was 68·5 per cent. It has been as high as 71 per cent. This factor is the ratio between the output and the possible output if the machines were run full load from the time each one is started till stopped. This is the percentage that tells on the costs of running, fuel, water, oil, &c.

The lamp connections have progressed in a fairly steady way. October has the largest number of applications. The maximum output has not reached more than 54 per cent. of the total lamps wired.

The underground work in the streets is, I presume, pretty well known to you. The copper strip is laid on porcelain insulators in iron culverts, which are water-tight. I do not mean that under a pressure they would keep out water, but owing to their construction, the lids overlapping the culverts, the ground in which they lie must be flooded before the water could rise high enough to enter through the seam. I have never known an instance of water in the culverts. Water does collect in the brick junction boxes, especially in Bath-street, and districts where we have heavy clay soil. Provision is made in all such for their thorough drainage. Where it is not possible to lay copper strip, indiarubber covered cables have been laid in cast-iron pipes.

There are, generally speaking, three wires on each side of the street ; in some cases there are only two wires, positive and middle on one side, negative and middle on the other. Where strip is laid, the positive is always next the building, and the negative always outside. Where cable, the positive is painted blue, middle white, and negative red. The entire network is connected together throughout the city, positive to positive, middle to middle, and negative to negative. There are only two conductors to each feeder, one positive and one negative. The middle wire is brought back to the station from several points, and has a sectional area of 1in. at the station.

Faults in the underground mains are easily found by means of a compass needle. The needle is placed on the faulty conductor and brought to be parallel with it by means of a strong directing magnet. The other conductor is flashed to earth, and the direction of the excess current due to the fault is noted. In this way it is easily traced. Nearly all the faults are caused by careless workmen.

There are now 382 consumers, who have applied for a current of 15,487 amperes, which represents roughly 46,460 8-c.p. 33-watt lamps, distributed somewhat as follows :—

CORRESPONDENCE.

A UNIVERSAL SHUNT-BOX.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The writer of the "Editorial Notes" in your issue of the 20th inst. is apparently compelled to admit that this form of shunt-box has some important advantages, a conclusion somewhat different from that to which an ordinary reader would be led by your article of the 6th inst. But he endeavours to explain away the errors observed when using ordinary shunts, and in so doing makes several mistakes.

In the first place, he assumes that the galvanometer with which the tests given on page 695 of your last issue were made (and which showed errors of 4 per cent. and 11 per cent. when used for condenser tests with the ordinary shunts) had "a serious amount of damping," and was "therefore badly suited for ballistic purposes." Secondly, he states that the error made in measuring the ratio of two steady currents can quite easily be attributed to slight want of proportionality between the deflections of the galvanometer and the currents producing them." Both these statements are incorrect.

As a matter of fact, the galvanometer in question was an excellent ballistic one, specially constructed for condenser work, and in the first condenser experiments quoted, had a logarithmic decrement of only 0 053. This, as anyone knows, is far from being "a serious amount of damping," especially for comparative tests such as tho·e under discussion ; and yet the apparent ratio of the capacities obtained by using the ordinary $\frac{1}{99}$th shunt was wrong by 4 per cent. What *is* "serious," however, is that with the ordinary form of shunt, *the act of shunting the galvanometer alters the damping*, and (unless this alteration is determined and allowed for) leads to incorrect conclusions. With the "universal shunt" the damping is independent of the shunt used, and, as shown in the figures above referred to (*see* p. 695), gives results practically right without the necessity of determining and making any correction whatever.

Coming now to the second statement, that the error in comparing the two steady currents can be attributed to want of proportionality, it is easy to see that this cannot possibly be the true explanation. For since the second current was 100 times the first, it follows that if the resistance of the $\frac{1}{99}$th shunt had been exactly $\frac{1}{99}$th that of the galvanometer, then

Digitized by Google

the two deflections would have been exactly the same whatever the law connecting deflection and current. The fact of the two deflections not being identical, absolutely proves that the resistance of the shunt and galvanometer were not in the ratio 1 to 99, although the conditions for promoting equality of temperature between the copper-wound shunt and the copper-wound galvanometer were (as pointed out by Prof. Ayrton at the meeting of the Institution of Electrical Engineers on the 12th inst.) exceptionally favourable.

Thirdly, I am quite at a loss to understand why "The selection of a shunt which happens to give a ratio of 99·63 for purposes of comparison was unfortunate, and greatly reduces the value of the experiments." Surely, the two first letters in "unfortunate" should be deleted, and the word "reduces" replaced by "enhances." As a matter of fact, the two currents in the ratio of 100 to 1 were chosen as being two widely different currents whose relative strengths we could conveniently measure with great accuracy, and the $\frac{1}{99}$th shunt was purposely used in the comparison by the ordinary method of shunting, *so as to eliminate all possible error that might otherwise result from want of proportionality of the galvanometer.* Had we not made this so-called "unfortunate" selection (or something equivalent) the tests would merely have amounted to a relative calibration of the galvanometer, whereas our sole object was to test the relative merits of the two methods of shunting. It was therefore essential to arrange the experiments so that *the shunts*, and *not the galvanometer*, were placed under test, and this was done in a very satisfactory manner by the method adopted.

Referring to the question of alteration of the resistance in the circuit produced by shunting, your criticism is correct. But with the usual shunting ratios $\frac{1}{10}$th, $\frac{1}{100}$th, and $\frac{1}{1000}$th, it is to be noted that for all values of r (the resistance permanently shunting the galvanometer) not exceeding 20·4 times the resistance of the galvanometer, our original statement holds good, viz., that altering the plug of our shunt-box produces *less* change in the resistance of the circuit from its original value, than if an ordinary shunt-box be employed.—Yours, &c.,

T. MATHER.

ELECTROSTATIC ERROR IN ELECTROMAGNETIC INSTRUMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In referring to this subject in your Editorial No es last week, you say that you "incredulously stroked the glasses of both instruments with a finger," but found no deflection in either case. May I suggest that perhaps your "incredulity" might have something to do with the failure of the unvarnished instrument to respond to the touch. But, joking apart, there is not the slightest doubt that merely stroking the glass with the finger will produce the effect stated in the Paper, and it is not at all necessary that the glass should be "rubbed briskly, if not violently, with a handkerchief," to deflect the pointer, for many times I have produced a deflection of 80 volts or more on the unvarnished 100-volt instrument, by a *single* stroke of my *finger* across the glass, without either the glass or my finger having been dried or specially prepared in any way whatever. In some cases the instrument had been standing on a bench in the laboratory of the Central Technical College unused and untouched for several days previous to the test, and the glass had become quite dusty. Not only have I obtained this result, but Prof. Ayrton and several of our students and staff have done likewise. Further, it is a well-known fact that certain voltmeters in central stations can be deflected by a stroke of the finger on the glass. For example, little more than a week ago the engineer in charge of an important low-pressure central station begged me not to stroke the glass front of one of the voltmeters on the switchboard, for he said that he could not be sure of its readings for five or ten minutes after it had been touched.

To give another instance, an electrical engineer of considerable experience informed me that he had returned a voltmeter, which had been fixed with an isolated plant, to the makers several times, with the complaint that it was vague and inaccurate. Each time the makers, after testing it, said the instrument was quite correct. Eventually the vagueness and inaccuracy were found to arise from the attendant taking a pride in his engine-room, and keeping his instruments clean, thereby electrifying the glass and producing the errors complained of.

Sticking gold leaf on the glass, as suggested by the "engineer of unusually large experience," whose letter you quote, will, of course, prevent the error; but this remedy has the serious disadvantage that gold leaf, not being transparent, the pointer is mostly hidden behind an opaque sheet. Now, the conducting varnish (not "hygroscopic varnish," as you term it) is not only as effective as gold leaf in preventing electrostatic action, but, being quite transparent, allows the whole length of the pointer to be seen.—Yours, &c.

T. MATHER.

ROLLASON'S WIND MOTOR.

TO THE EDITOR OF THE ELECTRCIAN.

SIR: We thank you for your notice in last week's issue. Your paper being an influential one, we hope you will allow us to correct some statements relating to the cost per horse-power. I take the figure 3-H.P. for 10 hours per day, this gives us a total of 30-H.P. per day. Assuming the light is required for three hours per day, a gas engine to accomplish this (direct lighting) would have to be of 10-H.P., working for three hours, thereby bringing the cost up to more than our motor (in addition to the cost of gas). I am taking summer breezes and lighting, as in the winter the winds are stronger, and consequently the motor developing more power.

We are completing our price lists, which compare favourably with other motors in the market, and are at present in a position to make them up to 20-H.P.

Thanking you, in anticipation of insertion.—Yours, &c.,

GEO. R. ROLLASON.

13, Berners-street, Oxford-street, W., April 25, 1894.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *April* 13, 1894.

General Electric Company.—This concern has issued its annual report, which shows a sad state of affairs, a shrinkage of assets of no less than \$12,450,000 being confessed, as against a surplus of over \$1,000,000 a year ago, and a surplus (that of the separate companies) of \$9,278,000 two years ago. Among the assets, patents and franchises are valued at \$8,159,264, though but few have any real value and these but a short life remaining, while the expenses which they have entailed in litigation have made them a burden rather than a source of profit. Of the other assets, amounting in all to \$25,300,000, \$4,200,000 are represented by manufacturing plant and real estate, \$5,500,000 by stock and bonds of manufacturing and local companies, \$4,800,000 by manufacturers' stock and material, \$8,900,000 by notes and accounts receivable, and the remainder by cash (\$591,000) and the value of work in progress. The liabilities consist of stock, \$34,711,000, debenture bonds and interest on same, \$10,083,000, notes and accounts payable, \$1,067,400, and sundries \$65,000.

The Niagara Plant.—No action has yet been taken for the transmission of power from Niagara though a half-dozen subsidiary companies have been formed for that purpose. One of these, on the plea of propelling canal boats by electricity, obtained a franchise, by corrupt political methods it is charged, permitting it to use the tow path and lands of the Erie Canal, which are owned by the State of New York, for the purpose of laying conduits and erecting buildings for the distribution of electricity. It now seems that the terms of the franchise are such that the grantee can erect generating stations anywhere on these lands, and thus compete in this manner with the scores of central stations now established in towns along the line of the canal. This is an example of the dangers to which legitimate business enterprises in the States are subjected through the power of corrupt politicians.

LEGAL INTELLIGENCE.

Wise v. Metropolitan Electric Supply Company (Limited).

The hearing of this case was resumed before Mr. Justice Stirling, on Wednesday. Counsel engaged in the case were:—Mr. Graham Hastings, Q.C., and Mr. Beaumont for the plaintiff; and Sir Richard Webster, Q.C., Mr. Phipson Beale, Q.C., and Mr. Vernon Smith for the defendants.

Sir RICHARD WEBSTER referred to the decision of Mr. Justice Kekewich in the case of Shelfer and Meux's Brewery Company against the City of London Electric Lighting Company, and said that that learned judge held that the liability of the Company with regard to nuisance still existed, but he would not grant an injunction under the circumstances of the case. He (Sir Richard) would show his lordship that they had an even stronger case against an injunction than had the defendants in the other action.

Mr. JUSTICE STIRLING said, unless there was something to distinguish the legal aspect of this case from the case referred to, he should feel bound to accept Mr. Justice Kekewich's construction of the law as to the liability.

Sir RICHARD WEBSTER said the question of law was the same, but his clients had an even stronger case as against an injunction. He then called

Mr. STEPHEN BABINGTON BARLOW, solicitor, member of the firm of Messrs. Barlow and James, solicitors to the defendants, who said he had a conversation with Mr. Hunt on June 1, 1892, and he made notes at the time of the substance of the conversation. Mr. Hunt said, in his opinion, the site at South Mews was the most suitable of any place between Oxford-street and Marylebone-road. He himself and the Vestry Clerk desired to have the Company in the parish. He further said the site had been occupied by a filthy mews behind small and old property. Mr. Hunt did not make the slightest suggestion that he did not approve of the site, or that it was not a proper site; nor did he say that he objected to White assigning his lease to the Company.

Mr. FRANK BAILEY, engineer to the defendant Company, said he was appointed to that position on October 1, 1889. Mr. Gordon had prepared the plans for the erection of the station, and he (witness) superintended the construction of the works. The question of possible vibration was most carefully considered, and no suggestion made with the view of preventing it was rejected without consideration. It was decided at first that the foundations should be a brick bed set in cement and resting upon a layer of felt, which, in turn, was placed upon sheet lead, whilst underneath that again were two or three feet of concrete. The foundations were perfectly isolated from the surrounding walls. The whole cost of the station, excluding the laying of the mains, was probably over £80,000. The first complaint, so far as he knew, was from the houses on the east side, and those houses were acquired by the Company, who put in the wiring for electric lighting, and let them to new tenants. So far as he knew, no complaint had been since received. Witness took two bedrooms and a sitting-room at No. 9, Manchester-street, and occupied them conjointly with Mr. Hick, from the beginning of January until about the middle of February. At that time four engines were running at the station. He made numerous experiments, but could never detect anything in the shape of vibration. Mr. Gillam, of whom these rooms were held, said he had not noticed any vibration, and the works had been no nuisance to him. He (Gillam) said he believed Mangan, the tenant of the houses purchased, had only complained in order to compel the Company to purchase. The houses were well kept up; but it was quite clear that they were not well-built. After receiving complaints from the immediately-adjoining houses, they carefully examined all the steam-pipe connections in the station, and made every provision they could think of to isolate all portions of the moving plant from the surrounding walls. It was suggested that the connection with the exhaust pipe might tend to increase the vibration, and that connection was cut off at the point where it left the engine, the joint being made good again with a copper sleeve. It was further suggested that the exhaust of the vapour from the top of the shaft set up pulsations in the surrounding atmosphere, and in order to counteract that a fan was applied, which blew air under pressure into the base of the exhaust pipe, but no difference was found in the working, and that led him to the conclusion that there was nothing in the suggestion; the fan itself caused far more disturbance outside the station than anything else. As the speed of the exciting-engines was rather high, it was decided to reduce it to the extent of 20 per cent. In 1892 complaints were received from the houses on the west side of Manchester-street; he could not at first believe that there could by any possibility be any vibration there, but after visiting the houses several times he did detect a slight tremor in No. 43. He reported the matter to his Board, and was instructed to do everything possible to remedy the trouble. He came to the conclusion that the only cause of the vibration was the presence of some sensitive communicating medium in the subsoil. He therefore sunk a bore-hole to learn something of the nature of the strata. Down to a depth of 25ft. he found a spongy clay which was more like mud than clay; at a depth of 25ft. he found what at first was supposed to be a layer of gravel, but which was afterwards discovered to be claystone. Below that claystone they came to very hard dry blue clay. This at once revealed the cause of the trouble, that they were resting upon a compressible bed. Witness submitted a plan showing a method of sinking pillars or columns down to the hard clay, and to brace the tops of the columns by a system of girders, which would form a platform upon which the engines would work. This plan was adopted, and the columns were sunk. They tested at the base of the column to ascertain whether the clay upon which they rested was really incompressible, and incapable of transmitting vibration downwards. When the columns were constructed, and after a complaint had been received from Mr. Wise, he made experiments with a beam and pencil, and found that there was a lateral movement. He then prepared plans for sinking and tieing together two diagonal struts or raking piles. It was clear from their observations that the vertical columns were not sustained by the material through which they were sunk; the clay was too soft to afford sufficient support to keep them rigid, and the function of the struts was to afford that rigidity which they could not otherwise obtain. One pair of struts had been sunk, and it was proposed to sink another pair at the north end of the engine-house. The cost of these remedial works was, up to the present, about £2,000. They were also sinking a trench on one side of the premises to the depth of 12ft., the effect of which would be to cut off any tremor on the surface, but would not cut off the lateral movement for the prevention of which the diagonal struts were put in. They thought it advisable to increase the rigidity of their engines by tieing together the top of the cylinders of the engines with the side of the alternators. From observations he had made, he should say the vibration observable was less in times of frost, if, indeed, there was any at all then. They used at the station the best Welsh steam coal. At the time of the coal strike the coal merchant could only obtain bituminous coal, which caused smoke. He had made observations to see what amount of smoke and dirt came from surrounding property, and the result was appalling. Within five minutes a piece of varnished cardboard 2ft. square was completely covered with smuts. He was at present making experiments with the view of reducing the noise from the machinery, but had not yet found the best remedy to apply. When the other works were completed they would, if the experiments were not successful, make such structural alterations as would lessen the effect of the noise outside by constructing double roofs, and other changes of a similar kind. They supplied 236 shops, 702 private houses, 6 churches, 4 public halls, and 21 hotels and public-houses, and they had further applications coming in every day.

Cross-examined by Mr. Graham Hastings: He did not say the nuisance was now entirely got rid of, but he believed it would be when the struts now being constructed were completed, which would probably be in about two months' time. He had in his first affidavit stated it as his opinion that the putting in of the vertical columns would prevent any vibration. He was prepared, if necessary, to clear out the intervening soft, spongy clay, but that was not contemplated in the works now proceeding. The trench had been completed for more than a month.

THURSDAY, APRIL 26.

On Thursday morning the cross-examination of Mr. Frank Bailey was resumed by Mr. Beaumont. Witness thought the lateral vibration at the top of the vertical columns was not more than two millimetres, or one thirty-second of an inch. If only one strut were used for the purpose of stopping lateral vibration the horizontal position would be the best, but with two struts tied together at the apex of the triangle, the bases being firmly embedded in the hard clay, the angle of 30deg. from the vertical or 60deg. from the horizontal was quite as useful. He accounted for the variation in length of the vibrations, as shown by diagrams put in of observations at plaintiff's house, by the variation in the speeds of the seven engines. The incidence of the vibration was of an extraordinarily erratic character; at the same time that it was very apparent in Wise's house it might be scarcely observable in the house next door, and sometimes it was greater on one floor, and at other times greater on another. He would not say that the evidence of Prof. S. P. Thompson and other witnesses as to the vibration was inaccurate or exaggerated, but slightly coloured. There was "artistic colouration" perhaps on the part of Prof. Thompson. In the latter part of the summer of 1891 cracks developed themselves in the chimney at the works, and the shaft was hooped and rebonded, but he did not come to any conclusion as to the cause of the cracks. It would be a very difficult matter to clear out the whole of the spongy clay under the engine foundations, and either fill it up with concrete: it was merely a question of time and expense, but it would not be a ruinous expense. Some part of the district now lighted from the Manchester-street station might be supplied from the Paddington station, but the whole district could not be transferred without their going to a great deal of expense in putting in new machinery of a special type. It had been intended to replace the present engines by engines of slower speed, but he had found it impossible to get alternators to suit the proposed new conditions

Prof. A. B. W. KENNEDY said he had been consulted by the defendant Company with regard to complaints as to the works at Manchester-street. He visited Mr. Wise's house at a quarter past six one evening in November last year. Seven engines were running at the time at a speed of 350 revolutions per minute; two exciters were running on the load and one was running light. On the second floor front he distinctly felt a vibration with a slow and irregular period, from four to eight per minute. In other rooms he also noticed slight tremors. The vibration was greater in the back room of the third floor in Wise's house than in any other room in that or any other house he visited. The houses were old ones, and he had no doubt if they were rebuilt and put up properly there would be no vibration. He did not hear any noise in houses on that side of the street. He visited other houses than that of Wise, but found the vibration much less, and in some cases not at all. The hum of the alternators was perceptible in some of the nearer houses. He went again on a later occasion, and had similar experiences. Prof. Thompson was present upon each occasion. With regard to the means adopted to nullify the effects of vibration, he quite approved of them. He was not prepared to suggest that the removal of the spongy clay and the substitution of concrete would be an improvement upon the triangular struts; in fact, he preferred the stiffening by means of the struts.

Cross-examined by Mr. Graham Hastings: As an addition to the struts a block of concrete might be of some use in minimising the tendency to vibration; but the combination of these two means would present a very

Digitized by Google

great engineering difficulty, and would also involve a difficulty in the running of the station.

Dr. JOHN HOPKINSON stated that he had made a personal examination *in situ* of the clay formation in which the vertical columns were embedded, and found it as hard and firm a base for a foundation as could be had anywhere. He thought it was most probable that the diagonal columns, when completed, would completely remove the vibration. He did not approve of the suggestion of filling up the void, if the soft clay were removed, with concrete, for the height would be so great in comparison with the width of the block as to make it of little use. Slower engines would probably diminish the vibration, but, on the other hand, would cause more noise.

Cross-examined by Mr. Hastings: Even if it had been known at the outset that this layer of soft clay was present, he did not know that he could say the site was a bad one. With that knowledge to begin with, they might have taken steps of a similar character, though at a lesser expense, to those which had now been taken.

Mr. ROBERT WALKER, F.R.I.B.A., District Surveyor for St. Martin-in-the-Fields, stated that he was employed by the defendant Company to prepare the plans for the buildings for their central station at South-mews, Manchester-street. He submitted the plans to Mr. Hunt, Lord Portman's agent, and explained them to him. A question was raised as to whether there might not be a nuisance caused by the smoke, but witness showed the means which would be taken to prevent any nuisance from that cause, and he raised no further objection. Mr. Hunt never suggested that the site was an inappropriate one for the works.

Cross-examined by Mr. Hastings: Mr. White (the original lessee under Lord Portman) and himself had a trial hole made to ascertain the nature of the soil. They sunk down to about 14ft. near the chimney shaft, getting on to the spongy clay. They built upon that, putting in a bed of concrete. It was quite enough foundation for any building. There was very little water in the clay at the time the trial hole was sunk.

Re-examined by Mr. Phipson Beale: It was summer time when his trial hole was made, and the clay was fairly hard, but it was of a saponaceous character, which would become soft and spongy with the addition of water.

This concluded the evidence. A brief discussion took place as to whether it was necessary to address his Lordship upon the Electric Lighting Act 1882, and the Provisional Order, or whether his Lordship would follow the decision of Mr. Justice Kekewich in the Meux and City of London Electric Lighting Company case. Mr. Beale read the decision of Mr. Justice Kekewich upon the point of law, that learned judge having held, as reported in *The Electrician* last week, that there was nothing in the Act or in the Order which would exempt the undertakers of electric lighting works from the liability to an action for nuisance. Subsequently Mr. Beale addressed the Court upon the evidence, and contended that it did not reveal a sufficient interference with the ordinary enjoyment of the premises to entitle the plaintiffs to maintain an action for an injunction. If there was any annoyance at all it was of the slightest character, and such as might reasonably be caused having regard to the general requirements of the neighbourhood in modern times as compared with the period at which the leases were granted to the complaining tenants.

The Court adjourned for the day upon the conclusion of counsel's argument.

Alabaster and Another v. Harness.

This case came before Mr. Justice Hawkins and a Special Jury on Monday and Tuesday last. The defendant was the Managing Director of the Medical Battery Company (Limited). The plaintiffs alleged that in 1892 a certain Dr. Tibbits brought an action for libel against them; and that the defendant unlawfully and maliciously, and without reasonable or probable cause, and without having any interest in the action, advised, procured, and instigated the said Herbert Tibbits to commence and prosecute the action; and that the said Herbert Tibbits, acting on such advice and instigation, did in fact, without any reasonable or probable cause, commence and prosecute the action. Alternatively, that the defendant unlawfully and maliciously upheld and maintained the said action. That the plaintiffs were thereby involved in trouble and expense, and expended £596 in costs, which sum they now claimed. The defendant pleaded that he had a common interest in the said action.

Mr. T. E. GATEHOUSE said that during the year 1892 his attention was called to certain electric belts sold by the defendant, and an article on the subject appeared in the plaintiffs' journal. On September 16th they learnt that a circular had been sent by the defendant to the various newsagents in London threatening proceedings if they continued to sell copies of the paper. They at once consulted Messrs. Lewis and Lewis, and on September 22nd a writ was issued against the defendant claiming an injunction to restrain the publication of this circular and damages. On September 23rd, there appeared in the journal an article headed "The Medical Profession and Electrical Belts," and commenting severely on a pamphlet written by Dr. Tibbits about Harness's belts, and on that day Harness issued a writ for libel against the plaintiffs in respect of their earlier articles. On October 6th Tibbits issued his writ in the action complained of. Tibbits stated at the trial that he was bringing the action for his own benefit, and that Harness was finding the money; and that he had not been solvent since 1885 or 1886. This action resulted in a verdict for the defendants, and the costs as between solicitor and client amounted to £596. The taxed costs as between party and party amounted to £435, of which not a penny had been received from Dr. Tibbits.

The witness was cross-examined about a defence fund which had been started, but he stated that his paper refused to accept any sum from the public for their costs, and he believed the subscribers to this fund had had their money returned.

OLIVER STOCKMAN said he had been a clerk to Mr. Fleet, who acted as solicitor to Harness and the Medical Battery Company. Asked as to what took place before Dr. Tibbits brought his action, witness said that there were interviews at Mr. Fleet's office while the action was pending and before the issue of the writ, at which Harness was present. When he was asked to give evidence he informed Harness of the fact, and the latter instructed him to tell all he knew. Harness wanted everything to come out.

J. F. S. CRIDLAND, Solicitor, said he was the solicitor to Tibbits on the record. His costs were paid by the Medical Battery Company. The cheques were signed by Harness and A. Smith, an accountant to the Company.

Mr JELF, Q.C., for the defendant, submitted there was no case, because Harness obviously had a "common interest."

The learned JUDGE said there could be no doubt a common interest would prevent any cause of action arising. The question of what was a common interest had never been decided, and should be fully discussed.

Mr. JELF intimated that he should call no evidence, and it was agreed that the jury should be discharged, and that the case should be adjourned for further consideration, and decided by the learned Judge alone on the facts already in evidence.

Moritz v. Lord Ardilaun and Others.

In this case, heard last week in the Queen's Bench Division, Dublin, before Justices Harrison, Johnson, and Gibson, Mr. W. M. JELLETT applied on behalf of the defendants, who are sued as the committee of the Kildare-street Club for an order for security for costs. The action was brought by Mrs. Rose Moritz to recover a sum of £170 on account of a contract for putting in electric light in the club premises, Kildare-street. It appeared that in July, 1892, the defendants advertised for tenders for the lighting of the club by electricity, with the result that the tender of the Manchester and Liverpool Electric Engineering Company was accepted. The contract was signed by George Moritz as manager. It was subsequently discovered that the Company was not a registered Company, and a long correspondence ensued, the outcome of which was an agreement to take the personal undertaking of the proprietor of the Company, it transpiring that it was really owned by one person. The contract was then signed by "R. Moritz," as proprietor. On February 13th a writ of summons was issued in the name of the Manchester and Liverpool Electric Engineering Company, and that was discontinued. The present action was then commenced, and for the first time they heard of the plaintiff, "Rose Moritz." The Company had since been wound up. The amount sued for was made up of £70, which had been deducted by the defendants for alleged delay, and the balance was for extras, the amount of the contract having been paid. The plaintiff resisted the application, and referred to a joint affidavit made by Rose Moritz and George Moritz, her husband, stating that since the Company, of which she had been the sole proprietor, had been wound up all its liabilities had been cleared off.

The Court made the order applied for.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "THE ELECTRICIAN" Electrical Trades' Directory and Handbook is NOW READY. This valuable book contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

TENDERS INVITED.—The Royal Free City of Arad (Hungary) invite tenders for the construction and carrying on of electric works to furnish electric light and power for the district with all the necessary plant and apparatus. Further particulars are given in our advertisement columns, and all other information, including conditions, &c., can be obtained on application to M. Salacz Gyula, Mayor of Arad, Hungary. Tenders have to be in by noon of July 1st.

——— The Directors of the Great Indian Peninsula Railway require tenders for the supply of telegraph and miscellaneous wire, &c., which must be in by Thursday next.

TENDERS ACCEPTED.—The Dublin Town Council have accepted the tender of John Fowler and Co. (Limited), Leeds, for the entire work for the extension of the city electric lighting plant for £8,050, on the condition that the buildings be executed by Dublin tradesmen, and that the boilers and copper steam and exhaust pipes be manufactured in Dublin.

Digitized by Google

Plant Wanted.—University College, Bristol, require prices of dynamos and motors. Particulars will be found in our advertisement columns.

Plant for Sale.—We would again call our readers' attention to the advertisement in another column of the electric plant offered for sale by Mr. H. Cuthbert Hall, 46, Queen Victoria-street, E.C., offers for which will be received up till Monday next, the 30th instant.

Sale.—An advertisement appears elsewhere, offering for sale by private contract the valuable and well-known electrical and telegraph plant and apparatus business carried on by Messrs. Latimer Clark, Muirhead and Co. at Westminster. All particulars can be obtained of Mr. J. Worley, 27, Leadenhall-street; Messrs. Trinder and Capron, 47, Cornhill; or of Messrs. Bircham and Co., 50, Old Broad-street, E.C.

Appointment Vacant.—The Corporation of Sunderland require an engineer to superintend the laying of mains and the construction of their electric lighting station, and after to act as resident engineer at the station. Further particulars will be found elsewhere, and applications must be sent in to the Chairman of the Highways Committee by May 12th next. Mr. F. M. Bowey, Town Hall, Sunderland, is Town Clerk.

Sale by Auction.—The whole of the electrical fittings of the Industrial Section of the recent Bristol Industrial and Fine Arts Exhibition are to be sold by auction in the buildings on May 10th.

Liquidations.—A meeting of the Caledonian Telephone Company, Limited (in voluntary liquidation), is to be held at Mr. Barton's, 109, St. Vincent-street, Glasgow, on May 23rd, at 3 p.m., to receive an account of the winding up.

Bankruptcy.—A receiving order has been issued in the estate of William Glover and William Henry Hobson, trading at 272, St. James-road, Old Kent-road, S.E., as Glover and Hobson, engineers.

Dissolution of Partnership.—Messrs. Vaughton and Titley, electrical engineers, of 26, Great Charles-street, Birmingham, have dissolved partnership. Debts will be paid by Mr. E. E. Vaughton, who continues the business.

Personal.—Mr. F. H. Nalder, of Messrs. Nalder Brothers and Co., was married on March 27th last, at Beckenham, to Miss H. M. Merry.

——— We understand that Mr. T. H. Parker, son of Mr. T. Parker, of Wolverhampton, has set up in business as a consulting electrical engineer in Stourbridge.

——— The National Telephone Company having acquired the business of the Home Telephone Company, Mr. John L. Newland, who was Manager of the latter Company, has now assumed the management of the Private Wire and Telephone Installation Company.

Underground Mains.—The underground work for the Edinburgh Corporation electric light scheme is now in progress. "Doulton" casing is being used, and about fifty miles of 2½in. ways on this system will be laid. The Sunderland conduits will, we understand, shortly be commenced, for which work about ten miles of 2½in. ways of "Doulton" casing is to be provided. Some bare copper mains in culverts will be laid both at Edinburgh and Sunderland, and Messrs. Doulton and Co., of Lambeth, are supplying special insulators for both contracts.

"Parish Councillors' Guide."—Messrs. Jordan and Sons, of 120, Chancery-lane, have just issued a handy guide to the Local Government Act by Messrs. H. C. Richards, W. H. C. Payne, and J. P. H. Soper. The object of the book is to give explanations and notes for the benefit of those who have dealings with the newly-formed local authorities. The authors promise a larger work dealing with the subject in greater detail, to be shortly published.

Messrs. Marryat, Lillywhite and Co.—In addition to a contract just completed for lighting Mr. W. Hazell's house at Russell-square, London, and contracts in hand for installation work at Manchester, Liverpool, Cardiff, Richmond, and London, this firm have just received instructions to put down a complete plant for about 200 16-c.p. lights for Mr. J. W. Kennedy, at the Horse-Shoe, Chatham.

Messrs. John Davis and Son.—This firm have sent us a catalogue relating to coaling and mining, surveying, engineers', and mathematical instruments. A large number of dials and compasses, &c., are illustrated, together with drawing materials, and general optician's goods.

Messrs. Gent and Co.—This firm have secured the contract for lighting the offices into which the centre of the Agricultural Hall, London, N., will be divided (over 100 in number), and also the stands and exhibits at the forthcoming shoe and leather fair.

Gas v. Electricity.—At the half-yearly meeting of the South-West of England District Association of Gas Managers, held at Salisbury last week, a general notion was expressed that so far from the electric light having been a detriment to the consumption of gas, its introduction had really acted as a stimulus to managers and companies to increase the business and to perfect the utility of gas in every possible way.

Electric Lighting of Trains, &c.—The flooring and sides of the brake vans carrying the accumulators on the electrically-lighted trains of the London, Brighton, and South Coast Railway are being coated with "anti-sulphuric enamel" to prevent damage by the fumes and spray given off from the batteries. This material is also being employed by the Birmingham Central Tramways to prevent possible damage to the cars from the storage batteries.

Electric Fire Risks.—An interesting and instructive lecture upon fire risks was delivered on Tuesday last by Mr. A. Barrett, of Cambridge, to the members and friends of the Norwich Insurance Institute.

National Telephone Company.—This Company announces under date April 20, 1894 (original date of circular March 13, 1894), that, "in order that the telephonic service in London may be brought to a state of the highest efficiency, the Company have decided to introduce the Twin Wire or Metallic Circuit System." The alarming announcement is also made that this will render necessary a rearrangement of the Company's exchanges, requiring that the present exchange numbers of subscribers to the National Company's system will have to be altered. There have been for some time past unmistakable indications of discontent amongst subscribers to the Company's metropolitan service, and the rearrangement of the telephone numbers will undoubtedly prove the last straw. The change will be most serious to those firms who, at certain periods of the year, prepare large quantities of stationery for their various offices, warehouses, &c., and so serious will be the dislocation of business arrangements entailed in the change of the telephone numbers that we shall be much surprised if an agitation is not started to prevent the rearrangement suggested by the Company's circular, in which subscribers are naively told that they will be informed at the earliest possible moment as to what their new exchange number is likely to be. As the alteration in the exchange numbers must have been under consideration long before the new contracts for 1894 and 1894-1898, were entered into by the present subscribers, the liability of subscribers to abide by the terms of their contract in the light of the serious change contemplated, is surely open to question. There must be many old subscribers to the system who would prefer to be without the telephone in preference to adopting other numbers than those by which they have become well known to their clients and friends.

Hooper's Telegraph and India-Rubber Works (Limited).—A circular has been issued by the Managing Directors of this Company, notifying that the estate of the late Mr. William Hooper having been taken out of Chancery, a limited liability company has been formed to continue the business.

Indestructible Gas and Ignition Tube Company (Limited).—This Company have just issued new circulars and price lists of gas engine tubes, and incandescent lamps and electric lighting plant and apparatus, of which they are either manufacturers or for which they act as London agents. The Company are sole agents in London for the "Duplex" high-speed gas engine, the "Crown" gas engine, and for the dynamos, arc lamps, carbons, &c., manufactured by Messrs. Conrady and Co., of Keighley.

Straker's Filtering Oiler and Oil Bath Bearing.—In this system of bearing lubrication, which has recently been brought out by Messrs. Straker, Whitworth and Co., the oil is supplied to the shaft from an oil bath enclosed within the pedestal. Attached to the shaft is a small milled wheel, the lower edge of which is immersed in the oil, and the rapid rotation of this oil-flyer carries the oil in a fine spray upwards to the top of the pedestal, from which it passes through a strainer to the bearing. The action can be maintained at any speed above 150 revolutions per minute. It is claimed that this system introduces a saving of 75 per cent. in the oil used.

Patent Office Library.—Number of readers during the week ended April 21st, 2,440.

Antwerp Exhibition.—A meeting was held on Wednesday last at the Mansion House, London, to settle certain matters of detail connected with the Antwerp Exhibition, which opens on the [illegible] prox. It was stated that everything pointed to the British section of the Exhibition being a great success.

Alleged Theft of Copper Wire.—At the Woolwich Police Court, Thomas Haynes and John Wenbourne were charged with stealing and receiving 280lb. of copper wire, &c., value £13. 10s., the property of Mr. W. C. Johnson, of Charlton, and, after some evidence had been offered, were remanded.

Digitized by Google

BLACKPOOL.—Efforts are being made to get the trams running again by Whitsuntide, and it is anticipated that by that time the line will again be worked by electricity from Foxhall to the north end of the line.

BRADFORD.—The Gas and Electricity Supply Company of the Corporation on Wednesday instructed their electrical engineer to draw up plans for an electric lighting station at Frizinghall.

BRECHIN.—At a meeting of the Town Council, held on Thursday, it was moved that a deputation from the Council be appointed to accompany the Montrose Town Council on their visit to inspect the electric light station at Coatbridge; but it was resolved to delay sending a deputation until the result of the visit of the Montrose Council was known, and what action was taken in that burgh.

CHELMSFORD.—At the meeting of the Town Council on Wednesday the Town Clerk intimated that the Board of Trade would not agree to a portion of the Council's draft Provisional Order, and after some discussion it was decided that the matter be left to the authorities in London.

CHURCH LIGHTING.—The Marylebone Presbyterian Church is to be renovated and improved, and the opportunity is to be taken of installing the electric light therein.

CLAIM FOR WAGES.—James Gifford Black, electrician, manager for Messrs. Spagnoletti and Crookes, on the electric lighting works at Hanley (Staffs.), was summoned by Thomas Shuling, a wireman, for a week's wages, at the rate of 35s. a week, in lieu of notice, and 7s. 10d. railway fare. The evidence showed that plaintiff came from Banbury, and in March was engaged by the plaintiff as a wireman on the electric lighting works at Hanley. He began work on March 31st, and on the following day the defendant complained of some of the work. Plaintiff stated that he was not responsible for the bad work, which was the fault of the carpenter who made the joints. The result was that the plaintiff said he would give notice on the Saturday. Defendant replied that he must either go at once or that evening. Plaintiff came back to work next morning, and when defendant saw him he wished him to take 12s. 6d. for the twenty hours' work he had done. Plaintiff asked for his railway fare, but defendant refused to give it, and Shuling took out a summons.—The defence was that it was the custom of the trade to give only an hour's notice.—Several workmen were called, and stated that with most firms it was the custom to give only two hours' notice to the men, but in some cases a week's notice was given.—The Stipendiary ultimately found for the plaintiff for £2. 15s. 4d. and £1. 4s. 6d. costs.

COUNTRY HOUSE LIGHTING.—Messrs. Drake and Gorham have secured the contract for the lighting of "The Rookery" for Baron W. Von Schroder. The plant will include a dynamo suitable for charging a D.P. battery of about 100 16-c.p. incandescents for nine hours.

DARTFORD.—The Electric Construction Company having written to the Local Board that they had seen that a member of the Board was preparing a scheme for lighting the town by electricity, and inviting a deputation to visit their works at Wolverhampton, it was announced at the last meeting of the Board that they were not prepared to consider the question of electric lighting, having just entered into a three years' contract with the Gas Company.

ELECTRICAL TRAMWAYS IN IRELAND.—The Dublin Grand Jury on Friday considered an application for permission to construct tramways from Dollymount to the Hill of Howth, and, having heard the evidence and arguments of counsel on behalf of the promoters of the Company, and on behalf of the Great Northern Railway Company in opposition, decided to approve of the proposed tramways; tramways Nos. 1 to 4 to be worked by electricity, and tramway No. 5 to be worked by electricity or steam.

EXHIBITION.—It is under consideration to celebrate the Jubilee of the Emperor of Austria by a great exhibition for the whole Empire, to be held at Vienna in 1898. The chief object of the exhibition is to illustrate the progress achieved during the 50 years' reign of the Emperor Francis Joseph.

FAREHAM.—The Chairman of the Local Board of Health has called a public meeting of ratepayers, to be held at the Foresters' Hall last (Thursday) evening, to take into consideratian the offer of the Fareham Electric Light Company (Limited) to sell their business and undertaking to the Local Authority.

FOLKESTONE.—A public meeting convened at the request of a number of the largest ratepayers to protest against spending £35,000 on the electric Light was held at Folkestone on Monday, the Mayor presiding. The speakers were all in favour of the electric light being introduced either by a private company or at a lower cost. A resolution proposed by Councillor Hall and seconded by Councillor Baker:—"That the spending of £35,000 to light such a small area as stated in the scheme passed by the Corporation on the 6th inst. would be extravagant and unnecessary," was carried unanimously; also "That a copy of the resolution be forwarded to the Corporation, and should they continue to proceed with the scheme, that copies be sent to the Local Government Board and the Board of Trade."

GREAT MISSENDEN.—The contract for the village street lighting by electricity has expired, and there will be no more public lighting until the autumn. The electric light will, however, be continued to be supplied to private consumers.

HULL.—Some complaint having been made as to the alleged excessive charges for electric light supplied to the Town Hall in comparison with the corresponding quarter of last year, Dr. Holder, the Chairman of the Electric Lighting Committee, has elicited from the Borough Engineer that the electric current had been used to drive a 1½-H.P. engine in the Town Hall, as well as for lighting several rooms, marquees, &c., for which no allowance had been made. Dr. Holden said that if the current for the engine had been taken from a separate meter a great saving would have been shown in the charge for lighting the Town Hall, and it was manifestly unfair to work the engine as had been done, and to allow it to be supposed that the increased consumption of current was due to the lighting of the hall. After some discussion it was resolved to lay down a separate meter for motor purposes.

IPSWICH.—At the meeting of the Town Council on Wednesday it was decided to at once take the necessary steps to obtain a Provisional Order.

KINGSTON.—The Town Council have resolved to apply to the Local Government Board for permission to borrow £6,000 additional capital for electric lighting purposes, in order to meet the increasing demand for the current.

LLANDUDNO.—Messrs. Bellis and Kingsland have forwarded the Improvement Commissioners a draft of the Provisional Order, which they propose respecting the electric lighting of Llandudno. The Commissioners have referred the Order to a Committee for consideration and report.

LITTLEHAMPTON.—To those gentlemen who had written to the Local Board on the matter of electric lighting for the town, the clerk was instructed at the last meeting of the Board to reply to the effect that, although the Board did not at present contemplate supplying the electric light in their district, they would not oppose the formation of a company for that purpose, subject to the conditions of ultimate purchase, &c., being satisfactory.

LONDON COUNTY COUNCIL.—At the meeting on Tuesday the Highways Committee reported that the Council on April 10th instructed them to consider the advisability of widening the footways of the Victoria Embankment by taking in a few feet of the carriage-way on each side, in order to allow the electric light standards to be placed on the sides of the carriage-way without interfering with the trees. With reference to this suggestion they pointed out that the footways are of great width, 20ft. on the river side and 16ft. on the other, and in order that the lamp standards might be clear of the trees the width of each of the footways would have to be increased by 8ft., and that of the carriage-way correspondingly reduced from 64ft. to 48ft. Having regard to all the circumstances, they were of opinion that it was not advisable that the course indicated in the reference should be adopted. They understood that the Parks Committee had now under consideration a suggestion that some of the trees should be removed to facilitate of the proper growth of the remainder; and they thought it advisable that, until some decision should have been come to upon this suggestion, the further consideration of the question of the position to be occupied by the lamp standards should be deferred. The Council adopted the Committee's report.

NEWARK.—At the quarterly meeting of the Newark Tradesmen's Association last week a discussion arose on the question of introducing the electric light into the town. Mr. Norledge said that several gentlemen had obtained the best expert advice, and had ascertained that the electric light could be supplied to Newark at practically the same price as the gas, and they were prepared to enter into an arrangement with the Corporation to establish a plant, and they proposed to light the principal parts of the town as an experiment. An installation in the north of England had been inspected, which had proved a great success from the start, and a similar plant could be laid down in Newark for £5,000 or £6,000. After some discussion it was resolved to ask the Corporation to take up the matter, Mr. Norledge saying that all the information that had been collected would be placed at their disposal.

POPLAR.—The report prepared by Mr. W. H. Preece has been presented to the district Board of Works, and will be considered at their next meeting. Mr. Preece states that, having obtained a Provisional Order, the Board is under an obligation to proceed with it, the principal question being whether the Board shall itself undertake the supply or whether the powers shall be transferred to a private company. He recommends the former course being adopted. The report points out that the price of gas is constantly rising, whereas the price of electric current is assuredly becoming less,

Digitized by Google

largely on account of labour troubles in connection with the former, and the expiry of patents in connection with the latter. Practically there now little difference between the cost of the two illuminants. The population of the Bow, Bromley, and Poplar district is estimated at 166,000, and the area covered by the Provisional Order represents about 6 per cent. of the whole. It is necessary to consider the probable needs of the entire district, and Mr. Preece recommends that full provision should be made for supplying not only the area covered by the Order, but the more extensive area not yet included. He estimates the probable ultimate demand at an equivalent of 50,000 8-c.p. lamps, and the installation of this number would cost about £150,000, and realise an annual income, at 6d. per unit, of £22,000, with a profit of about 6 per cent. on the capital outlay. Thirty-five arc lamps would be required to light the two principal thoroughfares in the district, at an estimated cost of £18 per lamp per annum. He also recommends that buildings should be erected capable of containing plant for the whole ultimate supply, but that to commence with only sufficient plant should be put in for a 10,000-lamp installation, at an estimated expenditure of £28,500, plus working capital, bringing up the amount to £30,000.

PORTSMOUTH.—We understand that the ceremony of switching on the electric light is to take place on the 9th prox., when a large and representative gathering will witness the inauguration at the works, and in the evening a banquet is to be given by the Mayor at the Town Hall.

SHIRLEY AND FREEMANTLE (HANTS.).—At the last meeting of the Local Board the Clerk read the minutes of an extraordinary meeting of Board whereat he was instructed to make application to the Board of Trade for a licence under the Electric Lighting Act. He had since received a communication from the Board of Trade, pointing out that it was unusual for Local Authorities to apply for a licence before they took up a Provisional Order. It was resolved to refer the matter to committee, as was also a communication from the Brush Company.

SOUTHAMPTON.—The Town Council on Wednesday referred to a committee the consideration of the advisability of acquiring the undertaking of the Southampton Electric Lighting and Power Company.

STAFFORD.—At the last meeting of the Town Council the tenders recommended for acceptance by the Electric Lighting Committee (as set out in last week's *Electrician*) were adopted. An attempt was made to substitute the tender of a local builder for that of Mr. Lovatt, but it was defeated by 17 to 13 votes.

SUFFOLK.—The Visiting Committee of the Suffolk Joint Committee have had under consideration the question of lighting the new infirmaries by electricity, the Medical Superintendent having submitted a report setting forth the relative merits and cost of lighting by gas and electricity, and an application was made to the Joint Committee at the last meeting for power to expend a sum not exceeding £1,720 for such purpose. After some discussion, however, it was decided to light the new infirmaries with gas while the present contract with the Woodbridge Gas Company continued.

SUNDERLAND.—A special meeting of the Highways Committee of the Corporation was held on Friday for the purpose of considering the progress of the preparations for lighting the principal streets of the town by electricity, and the question of the contract to be made with the gas company in view of those preparations. The Borough Engineer was of opinion that the works would be ready for supplying electricity next December. The present contract with the gas company expires in June, and the Committee decided to negotiate with the company for the purpose of entering into another contract for one, two, or three years, with power to withdraw all or any of the lamps (92) in the electrically-lighted area, and that in the meantime Prof. Kennedy be requested to prepare an estimate of the number of lamps required, their cost, and the cost of supplying them with electric current.

WOLVERHAMPTON.—The foundation stone of the new Corporation electric light works in Commercial-road is to be laid on the 21st prox.

WREXHAM.—The Town Council on Tuesday accepted the offer of the Wrexham Electric Lighting Company (Limited) to sell their Provisional Order for the installation of electric lighting in Wrexham and district for the sum of £350.

YORK.—At a meeting of the Streets and Buildings Committee of the Corporation, held on Tuesday, to consider the question of electric lighting for the city, it was resolved that the high tension system should be adopted, and the City Surveyor was instructed to prepare a report upon the tenders of four firms to be presented to an early meeting.

SMOKING CONCERT.—The second annual Bohemian concert in connection with the City Electric Athletic Club was held at the Café Monico, Piccadilly-circus, on Wednesday evening last. Mr. J. Cecil Bull acted as chairman of a most successful gathering.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

March 22, 1894.

6,046. L. A. P. LIÉNARD and H. E. A. LIÉNARD. London. Improvements in the methods of effecting the electrolysis of saline solutions. (Date applied for under Patents, &c., Act, 1883, Sec. 103, September 22, 1893, being date of application in France.)*

6,057. H. EDMUNDS. London. Improvements in electrical conductors and in the method of making connections between electrical conductors.

March 24, 1894.

6,039 J. A. KINGDON. London. Improvements in the means of protecting electrical conductors.

March 27, 1894.

6,212. M. A. CATTORI. London. Improvements in and relating to conduits for electric railways.*

6,218. W. P. THOMPSON. Liverpool. Improvements in or relating to electric keyboards for type-writing and type-setting machines and the like, also applicable for circuit-closing devices. (C. E. Allen, United States.)*

March 28, 1894.

6,241. F. A. R. READ and H. G. COLEMAN. Stoke-on-Trent. A method of depositing and affixing metals by electricity upon a medium which is fastened upon ceramic objects by burning in a kiln.

March 29, 1894.

6,315. A. L. SHEPARD. London. An improved rotary electrical differential controlling device.

6,323. W. M. MORDEY. London. Improvements in or relating to alternating current apparatus or circuits.

6,323. J. A. ARCHER. London. Improvements in electric battery apparatus.

March 30, 1894.

6,366. E. V. COOKE. Patricroft. Improvements in electric arc lamps.

6,368. E. A. HOOD and P. SIMON. London. An improved apparatus for tightening telegraph wires and the like.

6,389. R. HUTCHINSON. Glasgow. Improvements in making elastic or semi-elastic compositions for insulating and other purposes.

6,402. G. E. B. PRITCHETT, T. W. PRITCHETT, and A. G. GOLD. London. Improvements in electric accumulators.

6,417. A. ESSINGER and T. HARDEN. London. Improvements in connection with switches for electric current transformers.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d. each.

1893.

6,000. THWAITE. Electrofusion of steel.
6,233. DU BOIS. Electric clocks.
6,306. NIELSEN. Electric current meter.
6,780. DOUBLEDAY and SUSSMANN. Secondary batteries.
8,958. RIGOLA. Applying electricity to the body.
9,380. HADDAN (Reisinger). Breaking electric circuit.
9,557. PRENTICE. Dynamo-electric machines.
9,627. FARADAY. Electric light fittings.
9,641. HALL and PICKERNELL. Signal for telephone circuits.
9,864. EVERED and WATSON. Electric switches.
10,015. CROMPTON and DOWSING. Utilising electrical energy for culinary purposes.

COMPANIES' MEETINGS AND REPORTS.

Indo-European Telegraph Company (Limited).

The twenty-seventh ordinary general meeting of this Company was held on Thursday at Winchester House, Major-Gen. G. B. Tremenheere, R.E., presiding.

The MANAGING DIRECTOR (Mr. W. Andrews) read the notice convening the meeting.

The CHAIRMAN said: I am very sorry to tell you that since we last met we have lost from our midst Mr. Henry Weaver, who died last autumn. Mr. Weaver was one of the oldest and most prominent figures in the telegraph world, and a gentleman of great ability and ripe experience. I need hardly add that his services were valuable to you and to us all. Our Chairman, Mr. Herbert Tritton, having had a long illness,

Digitized by Google

I regret to say he has been obliged to go away for a charge, which we hope will restore him to health, and that we shall soon see him in his place again. From the figures set out in the printed report you will see that we have had a very prosperous year. We have realised £5,380 more than in 1892, but the expenses are rather in excess of the previous year. We are, nevertheless, enabled to place £15,000 to the reserve, to declare, with your sanction, a dividend, including the bonus at the rate of 10 per cent. for the year, and to carry forward £6,452 to the next account. The working of our telegraph has been carried on with great regularity. It is, as you are aware, 4,000 miles in length—from London to Teheran. After crossing the North Sea by our wires in two of the Government cables, the line passes from the German coast to the Russian frontier, 585 miles; through Russia, 2,382 miles; and Persia, 471 miles. It is extremely creditable to our staff and employés that the messages have been as a rule transmitted with great accuracy, punctuality, and speed, day and night, all along the line. The actual average time between London and Teheran has been eminently satisfactory throughout the year. The result has fortunately been equally satisfactory on the lines of the Government of India and on the Government lines in Persia and in the Persian Gulf. The through service from origin to destination, covering an average of some 8,000 to 9,000 miles, through almost every variety of climate, has left nothing to be desired. Of course, while giving the manipulating staff every credit, the engineering staff must not be forgotten, nor the excellent management which has to organise, control, and regulate the whole, producing the result which is seen in the prosperity of the Company. The Directors, looking at all the facts, at the large augmentation of the Company's business and work, have thought some recognition should be given of the valuable services rendered, and with this object we have set aside the sum of £4,000 from the receipts of the year for that purpose. We think that the occurrence in June, 1893, of the completion of the first 25 years of the incorporation of the Company would be a peculiarly fitting occasion to let the officers and staff see that the Company is not unmindful of services rendered, and I am glad to think from the applause just accorded to my statement that the shareholders cordially approve of this policy. The Directors are glad to say that the measure has given the staff great satisfaction and encouragement. Gentlemen, there is little more for me to say. As on previous occasions, and in continuation of a cautious policy, we have written down certain items this year which are included in our expenses account, and I think I may congratulate you upon the very sound position of your company. If any shareholders desire to ask any questions or make any remark, the Board will be happy to hear them. I will now move—

"*That the report and accounts now submitted be received and adopted, and that a dividend be, and is hereby declared for the half-year ended December 31, 1893, of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 20s. per share, both free of income tax, making in all 10 per cent. for the past year.*"

Mr. C. W. EARLE seconded the resolution.

Mr. STOCK hoped that of the £4,000 to be given to the officers a portion would be set aside for the executors or representatives of the late Mr. Weaver, who, he believed, did a great deal for the benefit of the Company.

Mr. MACANDREW asked if he was to understand that the £4,000 had been already deducted from the income of 1893, or was to be charged to the amount carried forward?

The CHAIRMAN: It has been deducted already. I may just say that we understand Mr. Weaver's family are left in very good circumstances, and we could not well distribute any money to his executors.

The resolution was then carried unanimously.

The CHAIRMAN: I now beg to move the re-election of Mr. John Von Berenberg Gossler and Mr. H. H. Meier, who retire by rotation in pursuance of the provisions of the Articles of Association.

Mr. C. HOLLAND seconded the resolution and it was carried.

Mr. STEVENS moved a vote of thanks to the auditors and their re-election.

Mr. STOCK seconded, and the motion was agreed to.

Mr. GARDINER (of Messrs. C. F. Kemp, Ford and Co.) said that as one who had occupied the honourable position of auditor of the Company for 26 years he desired not only to thank the meeting for re-electing his firm as their auditors, but he had also to thank them for what was a very unusual thing, namely, that the auditors should be thanked for their services. It was very nice to get their remuneration, but it was better still to get it with a vote of thanks.

Mr. STOCK then moved—

"*That the very best thanks of this meeting be given to the Chairman and Directors for their ability in conducting the business of the Company.*"

He said the Board had managed the Company for a long time with great skill, as was shown by the dividend declared on that and on previous occasions.

Mr. ST. LAWRENCE SMITH seconded the motion, which was adopted unanimously.

The CHAIRMAN briefly acknowledged the vote of thanks, and hoped that the attention of the Board to the shareholders' interests would be as successful in the future as it had been in the past.

The proceedings then terminated.

Great Northern Telegraph Company.

The following abridged report of the general meeting held at Copenhagen on the 21st inst. has been forwarded by the Company for publication:—

Mr. F. Zahle presided at the meeting, and the CHAIRMAN of the Company (Mr. C. F. Tietgen), in rendering an account of the working of the Company during the past year, stated that the twenty-fifth year of their existence had been a stormy one in several respects, and especially to the Company's cables. In Europe 11 of their cables had been subject to 22 interruptions, while 18 interruptions had to be recorded of six cables in the Far East. The cable steamer "H. C. Oersted" had been on active service for 177 days; the "Store Nordiske" for 218 days, of which only seven days have been on account of other parties. This explains the fact that the item of "sundry receipts" appears in the working account as a much smaller amount, and the expenses of the cable steamers as a much larger amount than usual. The interruptions have been not only more frequent than in former years, but also of longer duration. This was due to the stormy and unsettled weather that prevailed in European as well as in Eastern waters. In Europe some of the repairs have been effected under circumstances of special difficulty, as at the beginning of 1893 the movements of the cable steamer were hampered by ice. Both in Europe and the Far East it has been necessary to renew considerable lengths of the cables where they have been found corroded by rust. This is especially the case where the cable has been covered with seaweed and other vegetation on the bed of the sea. The expenses on account of spare cable charged to the reserve and renewal fund have therefore been rather heavy, and shareholders must be prepared for similar expenses in the future. The old cable picked up is, however, not entirely without value, as a large portion of the core is perfectly sound, and fit to be re-sheathed with new iron wires, and by taking advantage of this the cost of spare cable is sensibly reduced.

There has been a very brisk traffic over the Company's lines, in Europe especially, and also in the Far East. The receipts have in consequence shown an increase, but one by no means proportionate to the increase in work. This is due to several causes, which are entirely beyond the Company's control, but which, nevertheless, call for special attention. The first is the great and constant depreciation of silver. Three years ago the Company could effect their remittances from the Far East to Europe at a rate of exchange of 5s. 3½d. per tael, or 3s. 11d. per dollar; a year ago the value of the tael had declined to 3s. 10d., the dollar to 2s. 9½d., and at this moment a tael is worth only 2s. 8d., and a dollar only 2s. At the beginning of 1893 the Company endeavoured to meet the losses thus incurred by a moderate increase in the rate of exchange at which the charges were collected at their stations in China and Japan. Both the Japanese Telegraph Administration and the Eastern Extension Telegraph Company concurred in the expediency of this measure, but, unfortunately, the Chinese Administration refused to agree, and, consequently, it had not been possible to apply the increased collection to the whole of the traffic. The Chinese have not been satisfied with preventing the general application of this arrangement, but have started a direct competition of rates with the Company's cables. It was mentioned at the last general meeting that the Chinese had opened their first competing line across the Siberian frontier in March, 1893, but so confident were the Company of the superiority of their service, that although the new route might have the effect of decreasing the Company's revenue, they contemplated the result with perfect equanimity, provided the Chinese loyally carried out their obligations and did not underbid the Company. The correctness of this statement has been amply borne out by subsequent events, seeing that within six weeks after the opening of the so-called "Helampo Route" to the public, that route had to be closed and remained totally interrupted for three months. The Company, however, have been sadly disappointed in their hopes as to the loyalty of the Chinese in carrying out their obligations. Instead of competing with the Company at equal rates, as stipulated by the Russo-Chinese Convention, they at once commenced underbidding the Company by fixing lower charges to Europe. At their stations in the interior, they have even gone to the extremity of refusing to accept telegrams directed by the senders to go *viâ* the Company's cables, and have also refused to collect the charges officially notified by the Company. In addition to this, the Chinese Administration in October last began a severe competition with the Company for the local traffic between the ports where the cables are landed, viz.:—Shanghai, Foochow, Amoy, and Hongkong, by reducing their rates between those places to one half of those which, according to arrangement, had been in force since 1886, and this in face of the fact that the depreciation of silver had already virtually reduced the charges in the same proportion. The Company have met these and other provocations in a most considerate and conciliatory spirit. At first they tried by friendly remonstrances, followed by more formal protests, to induce the Chinese Administration to fulfil their obligations—unfortunately, however, without success. After that the Company applied to the Danish and Russian Governments, both of whom promised their support, and the Russian Minister at Peking, Count Cassini, who is also the representative of the Danish Government at that place, has actually succeeded in persuading the Chinese to take up a more correct attitude in several respects. There is, therefore, reason to hope that the Minister will also ultimately succeed in inducing the Chinese Administration to desist from contravening the Russo-Chinese Convention by underbidding the Company. In the meantime the war of tariffs continues, but fortunately the Company's case is so just, and their position so strong, both financially and legally, that they are perfectly able to stand a prolonged campaign if required.

Whilst the injurious influences hitherto mentioned relate only to the Far East, the third cause of the Company's revenue not having been in proportion to the increased work has chiefly affected the European traffic. This is the considerable reduction of rates inaugurated at the International Telegraph Conference, at Berlin, in 1885, and completed at the Conference at Paris in 1890. As this cause has been operating for a long period, it is possible to speak with authority as to its constant and detrimental effect on the Company's revenue as proved by statistics. The following Table shows the total number of telegrams exchanged every year over all the Company's cables since 1881, the year succeeding the application of the word rate to the European traffic, and also the exact traffic receipts, includ-

Digitized by Google

ing Government subsidies, which the Company have earned by their work, due allowance being made for losses on exchange.

	Number of telegrams.	Traffic receipts.	
1881	797,670	£225,192 10 4	
1882	884,410	230,382 16 8	
1883	910,532	243,826 14 2	Duplication of Far East cables
1884	921,259	266,080 6 0	
1885	937,561	262,259 12 5	Telegraph Confrnce. at Berlin
1886	961,259	241,408 14 1	
1887	1,065,538	250,783 0 3	
1888	1,227,420	260,150 15 9	
1889	1,265,996	267,828 15 0	
1890	1,319,912	*280,911 13 0	Telegraph Cnfrnce. at Paris; Laying of Swedish-English cable.
1891	1,405,315	*284,696 1 8	Duplication of Danish-French cable.
1892	1,417,912	263,045 19 8	
1893	1,531,271	275,593 0 6	

* The rise in 1890-91 is partly due to a temporary appreciation of silver.

It will be seen from this summary that the increase in traffic during the said period of 12 years leaves nothing to be desired. Although in some years—as, for instance, 1884-86 and 1892—the increase has been comparatively trifling, the period taken as a whole shows an increase in the number of telegrams transmitted of no less than 733,601, or about 92 per cent. This is ample proof not only of great commercial progress, but also of the activity displayed by the Company, who have spent during the same period some half a million of pounds on new cables in order to insure a satisfactory transmission of the growing traffic. The traffic receipts, on the other hand, present quite a different aspect. They, too, show a fairly satisfactory increase before the Telegraph Conference at Berlin (1885), considering that from 1881 to 1884 they increased about 17 per cent., or in about the same proportion as the number of telegrams. The reduced tariff adopted at Berlin, however, resulted in a sudden and marked decline in the receipts in 1886. It is quite true that the latter rose again by degrees during the next few years, but only to fall off once more in 1892 in consequence of the reductions adopted at Paris. And although a fresh rise made itself felt in 1893, the whole of the receipts in that year were only 3½ per cent. higher than in 1884, while the number of telegrams had increased by 610,000 or 66 per cent. during the same period. From a practical point of view, the receipts during the last 10 years must be considered as stationary, seeing that the average yearly receipts are actually lower than the receipts in 1884. When, at the same time, it is borne in mind that both the ordinary and the extraordinary expenses of the Company are necessarily increasing, and that considerable outlays are constantly required, in order to keep their cable system in a state of efficiency, even the most sanguine shareholder will no doubt agree that the circumstances referred to above give rise to serious reflections. It is not with the object of discouraging the shareholders that this subject is brought to their notice, but only in order to prove to those shareholders—especially in France—who now and again advocate a higher dividend at the cost of the additions to the reserve fund, that such a policy would be fatal to the Company. The present additions to that fund are absolutely necessary—firstly, because the expenses of maintaining and renewing the Company's lines are becoming heavier in proportion as the cables are getting older; and, secondly, because it is only by means of the accumulating interest on the investments of the reserve fund that the Company will be able to meet such further tariff reductions as cannot fail to be in store for them, and also to compensate for the cessation of the Government subsidies, when in course of time their concessions expire.

Although the results of the last ten years' working, when thus closely examined, are not absolutely gratifying, and although they clearly prove the necessity of the financial policy adhered to up to the present, it is still gratifying to study the financial recapitulation, comprising the first 24½ years of the Company's existence, which has been prepared by the Directors, and a copy of which can be obtained by any shareholder. This recapitulation shows total receipts of £5,474,533, against ordinary and extraordinary expenses of £1,664,573 on total net receipts of £3,809,997. These receipts have permitted a distribution of £368,250 in interest and amortisation of debentures, £2,474,527 in interest and final dividends on shares, £862,968 in reserve and renewal fund (less amounts written off), £35,443 in pension fund for the staff, £30,653 in remuneration to Directors, and a balance of £38,154 carried to 1894.

At December 31, 1893, the liabilities of the Company were £1,700,000, against assets estimated at £2,824,536, or an excess of assets of £1,124,536.

The yearly dividend has averaged nearly 7½ per cent., and the shares have attained more than double their nominal value, and it must therefore be admitted that the shareholders have every reason to congratulate themselves on the results of the past. With regard to the future, the Company can face coming events with equanimity, provided the shareholders are prepared to place the same confidence in the Board as hitherto, and to support their financial policy.

For the year 1893 the Board recommend that the extra dividend, the addition to the reserve fund, &c., be fixed at the same figures as last year.

The Directors have sustained a sad loss through the demise of their able and conscientious colleague, Mr. A. Garde, who has been on the Board since 1887. To fill the vacancy the Directors have invited His Excellency Vice-Admiral J. S. Meldal to join the Board.

Metropolitan Electric Supply Company (Limited).

The seventh ordinary general meeting of the Metropolitan Electric Supply Company (Limited) was held last Monday, under the presidency of Sir John Pender, G.C.M.G. M.P.

The SECRETARY (Mr. E. Cunliffe Owen, C.M.G.) having read the notice calling the meeting, and the report of the Directors having been taken as read,

The CHAIRMAN said: The accounts which are in your hands, and which have been prepared in the form prescribed by the Board of Trade, give such full details as to the Company's financial working that it will not be necessary for me to trouble you with more than a few remarks upon them. You will have seen from the capital account that the second £50,000 of the debentures authorised in 1892 have all been issued, making a total of £100,000, nearly the whole of which are held by our shareholders, showing the real interest which is taken by them in the progress and welfare of the Company. This issue of debentures brings our capital up to £600,000, which has practically been all expended, while the continual increase of new customers and the extension of mains will render it necessary for us to make still further provision for coming capital outlay. Referring to the other side of the capital account, you will find that the expenditure during the year has amounted to £35,072, the greater part of which has gone in mains and in the necessary apparatus and connections for supplying our new customers. There has also been some expenditure, which, though not large in amount, is of considerable importance to the Company's welfare. I refer to the expenditure at our Manchester-square station and at our Sardinia-street station. In the first of these cases we have found it necessary to alter and supplement the foundations of the engines and machinery in order to do away with any possible cause of complaint as to vibration, and I may add that these works are also having the effect of materially improving the working of our plant. You have doubtless seen that an action in reference to this question of vibration is in course of being heard. I am, of course, unable to refer to it in detail, but I can assure you that the Board are fully alive to its importance, and have left no stone unturned to provide for the interests of the Company being properly and adequately guarded. With reference to the expenditure at Sardinia-street, we have sunk a well at the station, and have put down a pumping engine for the supply of water, and from the experience we have gained, we have no doubt that we shall be practically independent of the water company and water rates, and that a very considerable economy will thus be effected in one of our prime necessities. One other point to which I must refer is the item of management charges, which now disappears for the first time from the capital expenditure of the year. In dealing with this matter the Board have considered it right to allocate a small portion (about £700) of the salaries of the engineer's department direct to the more important items of construction, by way of percentage, as representing the work done by that department in the way of supervision and actual expenses; but no appointment of general management expenses has been made to capital this year, the time having now arrived when, in the opinion of the Board, the whole of such charges should be borne by revenue. This leads me to the consideration of the revenue account itself, which in one sense has been somewhat disappointing. When in November last we issued a circular to you referring to the prospects of the Company, the Board were guided by the fact that in each of the three quarters which had then been completed, the income from current had shown an increase of nearly 50 per cent. over the corresponding periods of 1892. We had, therefore, reason to hope that the Christmas quarter, under normal conditions of weather and demand for light, would show a similar increase. Owing, however, to the remarkable absence of fogs, which, except from our point of view, has been so pleasant a feature of the past winter, and to the exceptional brightness of the general weather, the increase of revenue over the Christmas quarter of 1892 was only 8 per cent.; and this was in spite of the fact that our customers were increasing in numbers in about the same proportion as usual. But I would remind you that all lighting companies have been seriously affected by the past winter, and I am simply repeating what has already been dwelt upon by the chairman of all other kindred companies, whether gas or electric. In our case we estimate the falling off at about £10,000, which, after allowing for extra cost of production would have given an extra 1½ per cent. dividend on our capital. The total income for current has been £64,312, being an increase of £13,500 over 1892, which has been earned at an additional works cost of £6,600, which would have been only slightly increased to earn the larger income to which I have just referred. Looking at the details of this expenditure, it will be seen that, speaking generally, coals have increased by only £2,200, general stores by £800, station wages and salaries by £1,600, and repairs and maintenance by £2,000. With regard to the item of fuel, the Board took full advantage of the reduced price of coal at the time the contracts were made last year, but the small increase of cost under this head as compared with earnings is not so much due to economy in purchasing as to the fact which the Board have always desired to impress upon shareholders—that increase of output does not involve anything like a proportionate increase of cost. The more light we can sell the less per unit does it cost us to produce, and therefore the more profitable is our working. This observation also applies to the second item of oil, water, and stores, which need no further remark. Wages and maintenance make, however, an important item of increase, which is owing to the fact that our Rathbone-place and Amberley-road stations have been working during the year—not, as yet, to a sufficient extent to earn a large income, but still involving the expense of staff and maintenance as though they were. With all these considerations, the total works cost has been kept down to a figure which is most hopeful for the future. The items remaining for special notice are the general management expenses, which now appear for the first time as a full charge against revenue and the depreciation fund. With regard to management, very considerable economies have been in operation since last year, reducing the total by

nearly £4,000 from the cost in 1892; and as to depreciation, to which question the Board have given specially careful attention, without laying down any hard-and-fast principle for the future, we are of opinion, at present, that the amount we have advised should be written off (namely, £7,000), with the further £1,000 off preliminary expenses, fairly meets the case, more especially having regard to the fact that our business compels us to maintain our buildings and plant in the greatest condition of excellence and efficiency, the whole cost of which up-keep is charged direct to revenue, as is apparent from the figures before you. We now come to the final result as shown in the net revenue account No. 5—namely, a net balance (after providing for debenture interest) of £13,548. With this we recommend payment of a dividend of 5s. a share, carrying forward £1,073 to next year. We should have liked to recommend a larger dividend, but under all the circumstances we consider that the progress is very encouraging, and that our business, which I want you to realise, is still in process of development, is being established on a firm and satisfactory basis. Our lamp connection is still continuing to increase in very much the same proportion as heretofore, as will be clear to you from the diagram on the wall. You will also notice the plan which shows the houses we supply, and which gives a most encouraging idea of the gradual filling up of our areas, especially those in which we have worked longest. Paddington still lags behind, but that is our newest district. I ought to mention here that we are of opinion that the time has now arrived for the institution of transformer sub-stations in some of our more crowded districts. By the adoption of this system, which we have always kept in view, we hope to effect a considerable saving in the cost of supply. Before saying anything further, I think it is right to allude to a letter which I have received this morning from one of our shareholders. He intimates that he may probably not be able to attend the meeting, but that he feels greatly disappointed that in the speech which I made last year I alluded to a dividend of 5 per cent. You will remember, gentlemen, that that was not in my speech. It was a question that was put to me, and which I answered with the same confidence then that I would answer it to-day. My belief then was strong that, looking to the growth which we had before us of our system, we should, in all probability, pay a dividend of 5 per cent.; but I have shown you to-day that one of the quarters of the year was short by £10,000, and that made all the difference in our power to pay this 5 per cent. I mention that as showing the uncertainties and the changes that may take place from time to time; but I am pleased, to tell you to-day that in this quarter of March we have received £24,000, whereas in 1893, for the same quarter, the amount was only £19,000 while in 1892 we received only £13,000, and in 1891 only £10,000. I therefore think you will see that I am justified in speaking hopefully, though at the same time I want you to understand that we are engaged on a new business altogether. Science has not yet developed it to the extent that I believe science will develop it, but when I tell you that at the present time our machinery would, if continuously worked, produce in about 40 days the power which we need in the course of a year, you can see that we have a large amount of electricity at our command, and I hope that by-and-by we shall have customers to use it. There are other things connected with this system which require to be dealt with, and they are the use of this electric power for other purposes than lighting. We have not even touched any of these matters yet, but there is no doubt that these days of active competition will find some means of employing that enormous waste which exists now in the system. We have not the power which the gas companies have of storing our electricity in great reservoirs. If by scientific progress and development we can establish some cheap system of accumulating the electric power on an enormous scale it would add greatly to the advantage and dividend-paying power of these companies. Let me say another thing, because I know that a great many who go into these undertakings think that the wisdom of the Directors is such that they can do anything they please; but we have to learn as well as you. I may tell you that after a very careful investigation at the time this Company was formed, we made our calculations that we should receive at least £1 a light, and I was rather criticised for mentioning such a low price. Other experts thought that we ought to receive 25s. or 30s. To-day, however, the average amount that we receive is only 8s. 9d. per light You, therefore, see what Directors have to contend with, and with all the knowledge we possess it is very difficult for us to extract gold out of stone if there is no gold in it. I speak, however, with perfect confidence and belief in the future of electric lighting. It has so many advantages that I cannot conceive it being otherwise than prosperous. It remains, however, for your Directors to use all their knowledge and experience in conducting the affairs of the Company. Knowledge can only be gained by experience, but you may depend upon it that that experience will not be thrown away, and we shall do all we can to increase the dividend-paying powers of the Company. I may say that we have also to contend against a great many difficulties which have been set up by the Board of Trade, and I think the time will come—and will come very soon—when the different electric light companies will require to meet and consider the question of approaching the Board of Trade with a view to obtaining an alteration in the relations subsisting between that Board and these Companies. We are too much restricted, and we do not, I consider, get quite fair play, and until we get fair play from the Board of Trade, you may rest assured that we shall not be satisfied. There is competition, as you know, between companies. One company wants to try and do a little better than their neighbours; and there is a little of what is called "cutting," which will, I hope, be eventually stopped. I trust that we shall establish our system upon a broad and honourable basis, and that those who do the work the best will get the work to do, and that they will not be dependent upon making a small reduction here to-day and another small reduction there to-morrow, because all that will end in the necessity of an understanding with one another in order to protect our mutual interests. I think I have pretty well given you the whole of the details that it is in my power to give you. We have a suit pending about vibration. People take advantage of such undertakings as ours to try and get a little money out of us if they can do so. Until all these questions are settled, we shall have trouble; but still I hold that we have got the nucleus of an important business, and if we watch it carefully I think its development will be such that it ought to satisfy both the Directors and the shareholders. I now beg to move:—

"*That the report and accounts for the year ending December 31, 1893 presented to this meeting, be and are hereby approved and adopted, and that a dividend of 5s. per share on the whole of the Ordinary shares of the Company be and the same is hereby declared, such dividend of 5s. per share to be payable on May 1, 1894, to all holders on the Company's register on April 17, 1894.*"

Admiral of the Fleet LORD JOHN HAY, K.C.B.: I will second that.

Mr. H. E. YOUNG complained that the Chairman's anticipations regarding the dividend had not been fulfilled. He was a shareholder in the City of London Electric Lighting Company, the Westminster Electric Lighting Company, the St. James and Pall Mall Company, and the Liverpool Electric Light Company, and he was also a shareholder in other electric lighting companies in the country. He had had reports from all these companies this year, and they have all had to contend with the same weather which this Company has had to contend with. This was certainly a point in their favour, but from all the other companies he had received what he called better reports. From some of them he got a steady dividend of 5 per cent., and they all showed good hopes for the future. He also complained of the amount of the Directors' fees, and asked whether the Company had had any dealings with the Telegraph Construction and Maintenance Company, and whether it had had any dealings with Messrs. Verity and Sons. He concluded by moving a resolution, in effect fixing the Directors' remuneration at 800 guineas, instead of £2,100.

Mr. MUNRO seconded the motion.

Mr. ADAMS said that the question of the remuneration of the Directors was, if he remembered aright, dragged up last year or the year before, and he thought that the shareholders came to the conclusion that "the labourer is worthy of his hire."

The CHAIRMAN: In answer to the gentleman who moved the resolution, the solicitor informs me that that resolution is out of order. At the same time, while it is ruled out of order now, he can have it in perfect order for the next meeting. However, I want to take up the question which he has raised, and to deal with it irrespective of the question of order altogether. He has not been quite as straight as he might have been in mentioning other companies, which, I may say, are suffering quite as badly as we are. I think that when comparisons are made it will be found that we are building on a foundation which is likely to result in a permanent structure in the future. He has not told you with respect to the St. James Company that, while they paid their shareholders 7½ per cent. in 1892, they paid only 4½ per cent. in 1893.

Mr. YOUNG said that he took as an example not the St. James Company, but the Westminster Company.

The CHAIRMAN: You named the St. James Company.

Mr. YOUNG: But not, I think, in contrast with this Company, with which I compared the Westminster Company.

The CHAIRMAN: I like a little opposition myself and for attention to be drawn to any sore that may exist, because it is the duty and the business of Directors to heal sores if possible. In building up a concern like this we have a much larger area than any of the other companies. We have laid down about 70 miles of mains, and we are likely to run that up to 100 miles. That is a very large area of main work, and without the mains, you cannot, of course, exist. When we get our system completed, we shall then be in a position to deal with a much larger amount of income than we can at present in giving dividends, but you cannot expect in a new company of this kind that that should be the result at once. As this gentleman has said, I am connected with nearly all the Electric Telegraph Companies, but do not suppose that the connection with those companies does not give one knowledge and experience. My whole time is devoted to the work. I rarely leave this building from the time I come into it in the morning until I go home. I am attending carefully and closely to all these matters, and I think that my time and experience ought to be considered. It is not an ordinary concern you are dealing with, but a concern which is developing every day. It requires men of judgment to do this work, and I think we have such men at this Board. It is a very old story, after all, and I have had to deal with it in all these companies. The first thing which someone tries to do is to cut down the Directors' remuneration. We are not, however, what are called "guinea-pigs," but practical working Directors, doing our work well and faithfully to the shareholders, and if you think that we are not doing it faithfully, the sooner you get rid of us the better. At the same time, I have laid before you truthful statements—statements that can be investigated by any men you choose to appoint, and I hold that the shareholders, getting all the information that we can give them, should not ignore the fact that when we first approached them with the prospectus we based our estimates on £1 a-light, whereas we are now only receiving 8s. 9d. That will show you how we have had to adapt ourselves in order to meet that great difference. Had we been getting £1 a-light, we should have paid you a dividend which would have astonished you. However, the future is there, whether you leave us to conduct the Company or appoint others. Depend upon it, however, that it is not a good thing to make changes when a concern such as this is growing, although my co-Directors and myself are ready to do what the shareholders wish. My experience in electricity entitles me to say that I have never yet misled the shareholders or put before them anything that was not actually true and accurate. The question was put to me whether we have any connection with the Telegraph Construction and Maintenance Company. We have no connection with them, excepting, I believe, that we have a small sample of their mains to lay down and to test alongside

Digitized by Google

of the Company. It is two miles out of 245 miles. That is all the connection we have with the Telegraph Construction Company. So far as regards Messrs. Veritys doing work for us, we do something for them in supplying them with current, but they do nothing for us. If, therefore, you thought there was any jobbery—because it is as well to come to the point at once—you were in error. Our connection with the Telegraph Construction Company, so far as regards the telegraphs, is very important, but, as I have already said, our relations with them so far as this Company is concerned are very small, while at the same time they are as pure as crystal glass. If there is any other question to be put to me I shall be glad to answer it.

Mr. ADAMS asked what number of lights could be got with their present capital and mains?

The CHAIRMAN: Your first question is rather difficulty to answer, but, so far as I can see, we can get at least 50,000 more lights, and probably double that number. There is one thing, however, that I find about this question of electric lighting, and I find it in my own case. I use the electric light from the Westminster Company. I have a good many lights in my house at Arlington-street, but it is marvellous how I have learned to be economical in its use. When gas is lighted it continues alight generally until the household retires, but with the electric light it is turned off when its use is no longer required. In my own case, when I go down to dinner I turn the light off, and I turn it on again when I come back. The greatest economy is practised in connection with the use of the light. As far as I can see, the margin of light we have still at command ought to give us a very considerable dividend when we get it fully employed.

Mr. POLLOCK said he thought that a circular was sent out in the autumn telling the shareholders that the dividend declarations would be not once a year, but twice a year. Was there any alteration in regard to that question?

The CHAIRMAN: That is a matter that has been very carefully considered. I think I said when we talked about this matter of half-yearly dividends that we would declare them the moment we had such a number of lights taken up as would enable us to pay such a dividend. That is still the intention of the Board, but it is a very considerable expense to hold half-yearly meetings. What I have thought was that sending out a sort of letter would answer the purpose. I think it is quite right that shareholders should be informed about their affairs twice a year. I have no objection to sending you a letter every half-year, or to meet you every six months, but we desire to keep down the expenses in every way. When we get into an easy position it will give me the greatest possible pleasure to meet you and tell you how we are going on, and encourage you as you would encourage us in the work we have to do. What I propose to do at the end of the six months is to send you a statement showing the position of the Company. It is, however, difficult to fix upon the proper time to do so, because, as I have said, we expected to receive £10,000 more, and the absence of fog deprived us of that amount and made all the difference in addressing you to-day as rather discontented shareholders. I am a large shareholder, and am discontented, too, but next year I look forward with great hope to being able to declare a better dividend than that which we recommend on the present occasion.

Mr. MUNRO asked whether it was intended to fill the two vacancies on the Board?

The CHAIRMAN: No; that is one of the economies we are practising.

Mr. MUNRO thought that the auditors' fees were very large.

The CHAIRMAN pointed out that the amount included the Board of Trade's fee.

Mr. MUNRO inquired what the recognised fee of the auditors was?

Mr. JOHN GRIFFITHS replied that no fee had been fixed. He should like the shareholders to understand that what the Directors required of them was a great deal more than usually devolved on auditors. They were quite prepared to act as auditors for the usual fee, and for such work they would accept a very reasonable fee; but if they were called upon to perform, as they were, a continuous audit of the accounts, they would require the remuneration they had hitherto been paid. A very large proportion of the expenses this year for auditing had been absorbed by the Board of Trade on account of their official audit.

Mr. HILL thought that as comparison had been made between this Company and the Westminster Company, he would like to know how the question of capital bore.

The CHAIRMAN: I think that the less we say about our neighbours the better. You ought to be satisfied, I think, with what we tell you in our report, and you can yourselves look into the reports of other companies. I only ask you to look carefully into the affairs of this Company, and if you are shareholders in them, to look carefully into the affairs of other companies, and then make up your mind and form your own judgment whether we are acting wisely and properly, and in the interests of the general body of the shareholders. I believe that at the present time all the companies are more or less disappointed because they are not paying larger dividends. I have already told you that I am disappointed in the case of this Company on that account, but I see that there is a great future for us, and I am disposed to be patient. It is a new source of business. When gas was first established, those connected with that industry went through a great deal more trouble than we; and I say that looking to the advance of the electric light already and its youth in every sense, I anticipate its becoming one of the best investments in the City of London.

Mr. JOHN NEWTON said that about three years ago he took the same line as Mr. Young did, and referred to the number of companies that Sir John Pender was connected with. He pointed out that that gentleman was trying to control a capital of £20,000,000, that he was a Director of so many companies, and this, that, and the other. He then felt a little sore because his friends had been induced to put their money into it. Since then their capital had doubled, because they were then laying the foundation of a vast business, and they had got the benefit of it. It was that that caused him to rise and say that Mr. Young had made a mistake in one of his remarks. The Companies which the Chairman was connected with as regarded telegraphy had been enormously successful.

Mr. YOUNG: I did not say that they had not been.

Mr. NEWTON said he thought that Mr. Young had stated that where gentlemen were Directors of a great many companies it would be found that those companies had large amounts of debenture capital, and paid small dividends. The telegraph companies were burdened with a large amount of debenture capital, to which he objected, but they were, nevertheless, getting good dividends. Theirs was a company in which he thought they could very wisely wait patiently, and they might be sure that if they paid those who looked after the property well, it would be well managed.

The CHAIRMAN: You have heard the remarks which have been made by the different speakers, and you have heard my reply; and I will now ask you to approve of the resolution which I have moved, and which had been seconded by Lord John Hay.

The resolution was unanimously adopted.

Sir EYRE M. SHAW, K.C.B., then proposed the re-election of the retiring Directors, Lord John Hay, Mr. Joseph Charles Parkinson, and Mr. John Denison Pender. Those gentlemen had, he remarked, brought to bear on the business of the Company all the experience and knowledge which could be obtained in a lifetime of business habits. They had rendered very great service to the Company.

Admiral Sir GEORGE H. RICHARDS seconded the motion, which was unanimously adopted.

The auditors, Messrs. Deloitte, Dever, Griffiths and Co., were also re-elected.

A cordial vote of thanks was then passed to the Chairman and Directors for their services in the past year.

The CHAIRMAN: On behalf of my colleagues and myself I beg to thank you. I assure you that I always prefer that any feeling or grievance of any kind should be fought out at these meetings. We come by degrees to get a thorough knowledge of our shareholders, who on their part come to get a thorough knowledge of the Directors. You may depend that "unity is strength," and I have not the slightest doubt in telling you that I am quite sure that we shall become better friends every time we meet.

The proceedings then terminated.

Brazilian Submarine Telegraph Company (Limited).

The following is the report of the Directors to be submitted to the forty-first ordinary general meeting, to be held at Winchester House, Old Broad-street, E.C., on Wednesday next, May 2nd, at noon:—

The revenue for the half-year ended December 31, 1893, amounted to £96,261. 16s. 6d., and the working expenses to £24,284, 12s. 4d. After providing £12,880 for Debenture interest and sinking funds, and £1,423. 1s. 9d. for income-tax, there remains a balance of £57,674. 2s. 5d., to this is added the sum of £3,533. 6s. 9d. brought forward from June 30th last, making a total of £61,207. 9s. 2d. First and second interim dividends, amounting to £39,000, have been paid, and £20,000 transferred to the reserve fund, leaving the sum of £2,207. 9s. 2d. to be carried to the next account.

The receipts for the half-year include the sum of £1,500 dividend to June 30, 1893, on the Company's shares in the African Direct Telegraph Company (Limited).

In accordance with the provisions for repayment of the first issue of debentures, dated July 31, 1884, 187 bonds, representing £18,700, were drawn on the 20th inst. for payment at par on July 31st next. By this payment the first issue of debentures will be extinguished, and a reduction will be effected in the expenses of £19,360, the annual amount of the sinking fund and interest now payable in respect of this issue.

The new land lines between Buenos Ayres and Valparaiso constructed by the Pacific and European Telegraph Company (Limited), in which your Company has acquired a considerable interest, were opened for public service on March 19th last, with satisfactory and promising results. We are thereby again enabled to carry traffic to and from the West Coast of South America, and the public are thus afforded further facilities for telegraphic communication.

The various sections of the Company's line are in good working order.

Submarine Cables Trust.

The following is the report of the trustees to be presented to the twenty-third ordinary annual meeting of the certificate holders, to be held at the offices of the Trust, 50, Old Broad-street, London, on Thursday next, the 3rd prox., at 1 p.m.:—

The revenue for the financial year to April 15, 1894, including the balance of £80. 3s. 3d. brought from the previous accounts, amounted to £22,672. 19s. 5d.

During the past year the following coupons have been met:—

Due.	Paid.
April 15, 1893	£1. 10s. balance July 14, 1893.
October 15, 1893	£1. 15s. on account October 16, 1893.
	£1. 5s. balance February 1, 1894.
April 15, 1894	£1. 15s. payable April 16, 1894.

The expenses of the Trust amounted to £1,301. 7s. 4d., and the payments on accounts of the coupons to £21,131. 5s., together £22,432. 12s. 4d., leaving a balance of £240. 7s. 1d. to be carried forward.

The trustees regret to report the death, on May 7, 1893, of their colleague, Sir James Anderson, who was one of the original founders of the Trust. The meeting will have to elect two auditors for the current year; Mr. John G. Griffiths and Mr. John Gane offer themselves for re-election.

NEW COMPANIES. STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1893, pages 320-348, *&c., &c.*]

THOMAS PARKER (LIMITED).—This Company was registered on April 19th, with a capital of £75,000 in £10 shares, to carry on business as electrical and mechanical engineers, electricians, and manufacturers of and dealers in machinery, materials, stores, appliances, and apparatus of every description applicable for or in connection with the supply, or use, of electricity or magnetism for any purpose, and to generate, accumulate, distribute, and supply electric, magnetic, or other force, for the purposes of light, heat, sound, motion, &c. The subscribers (with one share each) are:—John H. Woodward, Edmund S. G. Rees, William Armistead, Charles H. Iles, Lawley T. Smith, Mein Wilkie, and Robert Willcock, all of Wolverhampton.

JOHN SIMPSON (LIMITED).—This Company was registered on April 18th with a capital of £15,000, in £10 shares, to acquire the weaving shed, gas works, electric lighting works, &c., at Hapton, Lancs., the property of John Simpson, and to carry on the business (*inter alia*) suppliers of gas and electricity for the purposes of light, heat, and motive or other power.

WILLIAM SMITH AND BROTHERS (LIMITED).—Capital, £100,000, in £10 shares, machinists, iron and brass founders, metal workers, boiler makers, millwrights, tool makers, implement makers, mechanical engineers, &c.

TRAMWAY MOTOR COMPANY (LIMITED).—This Company was registered on April 18th with a capital of £200,000, in £10 shares (of which 5,000 are Preference), to enter into and carry into effect certain agreements to be made with the Connelly Motor Company (Limited), George. F. Mellen, and William N. P. Reid, for the acquisition of certain inventions, and in relation to the employment of motive or other agencies in tramways, railways, carriages, ships, &c.

VALENCIA AND ALBERIQUE TRAMWAYS COMPANY (LIMITED).—This Company was registered on April 17th with a capital of £1,000, in £1 shares, to acquire from Joaquin Latorre a concession granted by the Spanish Government for the making of a system of tramways between the towns of Valencia and Alberique; to enter into and carry into effect two agreements with the vendor for the acquisition of the concession, and for the construction of the tramways; and to carry on the business of tramway and omnibus proprietors, electrical engineers, and contractors for electric lighting in the Kingdom of Spain.

VULCAN GAS ENGINE COMPANY (LIMITED).—This Company was registered on April 14th with a capital of £1,000, in £1 shares, to enter into and carry into effect an agreement between Henry M. Dimsdale and the Company for the acquisition by the latter of certain patents relating to improvements in the construction of gas engines, and to carry on the business of engineers, tool makers, iron and brass founders, boiler makers, &c.

"WILLIAMS" VALVELESS ENGINE COMPANY (LIMITED).—This Company was registered on April 19th, with a capital of £25,000 in £1 shares, to carry on the business of engine and boiler makers and builders, metal founders, mechanical, electrical, and general engineers, &c.

ANDERS' TELEPHONE COMPANY (LIMITED).—The statutory return of this Company, made up to March 26th, has been filed; 3,607 £1 shares have been taken up, of which 3,000 were issued as fully paid to the vendors, George L. Anders and Walter Kottgen. Upon the remaining 607 shares the full amounts have been called and paid.

ANGLO-PORTUGUESE TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to April 12th, has been filed. The nominal capital is £75,000, in £1 shares, and of these 50,000 were issued as fully paid to the Edison-Gower-Bell Telephone Company (Limited), of 53, New Broad-street, London, E.C., who now hold 37,400 shares. Share warrants, comprising 10 shares each, are outstanding to the extent of £4,020.

BIRMINGHAM ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to March 20th, was recently filed, when the whole nominal capital of £100,000, in £5 shares, was subscribed for and allotted. Upon 20,000 shares a call of £2 per share has been made, while the full amount has been called on the remainder, resulting in the receipt of the full amount of £70,000.

BRITISH ELECTRIC LIGHT COMPANY (LIMITED).—At the time of filing the annual return of this concern for 1894, 8,641 shares of £10 each were taken up, of which 1,145 were issued as fully paid. Upon the remaining 7,496 shares the full amounts have been called and £74,960 paid.

BRITISH ELECTRIC PROPULSION AND TRACTION COMPANY (LIMITED). In consequence of neglect to file annual returns, steps are to be taken to strike the name of the Company from the Register or to enforce the penalty for such neglect.

BRITISH VOLTA ELECTRIC GLOW LAMP COMPANY (LIMITED).—The statutory return of this undertaking shows that out of a nominal capital of £2,000, in shares of £1 each, 542 have been taken up, of which 300 were issued as fully paid to William Habgood, and 100 to Edwin C. Lacey, for their interest in Provisional Patent No. 16,514 of 1893, for "Improvements in electric incandescent lamps." Upon the remaining 142 shares a call of 6s. per share has been made, resulting in the payment of £36. 13s., and leaving £5. 19s. in arrears.

GALLOWAYS (LIMITED).—The annual return of this Company, made up to March 12th, has been filed. 2,108 shares of £100 each had been taken up out of its nominal capital of a quarter of a million. Upon each of these shares the full amount has been called, and £210,800 has been paid in respect thereof.

GORSEINON ELECTRIC LIGHTING COMPANY (LIMITED).—The statutory return of this Company, made up to and filed on March 22nd, shows that 786 shares have been subscribed for out of a nominal capital of £1,000, in £1 shares. Upon each of these shares a call of 7s. 6d. has been made, resulting in the payment of £273, and leaving £21. 15s. in arrears.

CITY NOTES.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—Notice is given in our advertisement columns that a drawing of 111 Four per Cent. Mortgage Debentures and of 14 of the Four per Cent. Registered Debentures (Series B) of this Company will take place at the offices, Winchester House, E.C., on Tuesday next, at noon.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—Our advertisement columns set out the numbers of the 187 Five per Cent. Debentures (1884 issue) which were drawn at the eighth and final drawing at the offices, Winchester House, E.C., on Friday last. These Debentures will be paid off at par on July 31st, at Parr's Banking Company and the Alliance Banking Company (Limited), Bartholomew-lane, E.C., after which date the interest thereon will cease.

CHARING CROSS, EUSTON AND HAMPSTEAD RAILWAY COMPANY.—We announced last week that the amount received in response to the application for capital had been returned to the subscribers. It is now stated that the prospectus is to be revised with the view of placing the scheme again before the public later in the year.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended April 22nd were £886, as against £851 in the corresponding period of 1893, being an increase of £35. The total receipts for the half-year amounted to £14,612, as against £14,568 for the corresponding period of 1893, an increase of £44.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The Directors forward the following returns relating to this Company for the quarter ended March 31st last, and state that it is their intention for the future to publish similar returns at the expiration of every quarter:—

	Quarter ended March 31st.	Corresponding quarter last year.
Revenue from sale of current for public lighting	£3,100	£2,778
Revenue from sale of current for private lighting, &c.	12,460	5,061
Total	£15,560	£7,839

No. of 8-c.p. lamps connected March 31, 1894, 84,634; increase during quarter, 19,293. No. of 8-c.p. lamps connected March 31, 1893, 85,275; increase during corresponding quarter last year, 15,034.

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The 16th ordinary general meeting of the shareholders of this Company will be held at the offices, 19, Great Winchester-street, E.C., on Tuesday, at 1 p.m. The Register of Transfers was closed on Tuesday last, and will remain closed until Wednesday next.

PANULCILLO COPPER COMPANY (LIMITED).—An extraordinary general meeting of this Company was held on Wednesday, at Winchester House, London, E.C., when resolutions were passed authorising the Directors to transfer the undertaking to a new company, to be called the Central Chili Copper Company (Limited), to be formed with a capital of £280,000.

SAN PAULO GAS COMPANY (LIMITED).—At the meeting of this Company, Mr. Frederick Delmar, who presided, said that, "with regard to the question of electric light competition which was alluded to on former occasions, he did not think there was much to fear, for several reasons. In the first place, with electric light a large expenditure had to be incurred in the first place for the cost of wiring, &c.; and with regard to the incandescent lamps, which were a great feature in electric lighting, the current was charged for at the rate of 7d. per Board of Trade unit, which, worked out volume for volume, gave a result in cost of about one-third more than gas. It was his opinion that under those circumstances they need have no fear, as the electric light would only be adopted by the richer portion of the community, while the poorer would continue to use gas. Added to that there was always a field for the utilisation of gas into which electricity could not enter; such as for cooking purposes and for heating and ventilating apparatus. They need, therefore, have no anxiety for the future." The speaker is evidently uninformed of the steady progress which is being made in the application of electricity to cooking and heating apparatus.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee by the Telegraph Construction and Maintenance Company (Limited) to grant a quotation to their £150,000 Five per Cent. Debentures in lieu of £150,000 Five per Cent. Bonds expired January 1, 1894. The Committee have appointed this day (Friday) a special settling day in the partly-paid scrip of £100,000 Five per Cent. Debenture Stock of the City of London Electric Lighting Company (Limited), and have ordered these securities, as well as the undermentioned, to be quoted in the Official List:—National Telephone Company (Limited), further issue of £74,983 Four and a-Half per Cent. Debenture Stock; Oriental Telephone

Digitized by Google

and Electric Company (Limited), 171,504 shares, Nos. 1 to 171,504, in lieu of those of the old Company of the same name; W. T. Henley's Telegraph Works Company (Limited), 6,837 Ordinary shares, Nos. 602 to 1,091, and 1,182 to 7,528.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended April 20th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited) were £2,940.
